Other aspects of the food and agriculture program include a further 20 percent increase in the use of fertilizer—already double the prewar consumption; improved farm credit facilities; and expanded research and educational projects.

Capital investment required to modernize and mechanize the existing plant and expand to the goals established is equivalent to about \$1.8 billion. This is only three and one-half times the value of the annual return in decreased imports, so the program will pay for itself quickly in terms of foreign exchange savings.

What is ECA's contribution to this program? It is, first, financing about 13 percent of British food and agricultural imports—that part of the imports which must come from dollar areas and which is beyond the dollar resources of the United Kingdom without assistance. This enables the United Kingdom to maintain a monotonous diet about two percent lower in calorie content than prewar. Cereals and dairy products are the major food imports

financed by ECA funds. Food alone comprised approximately 46 percent of ECA imports into the United Kingdom from April 3 to October 15, 1948, and is estimated at 33 percent of the total in 1948-49.

A second important specific contribution of ECA to the food and agriculture program is its financing of certain types of agricultural machinery and spare parts from dollar sources. This machinery is of a kind and type not made in Britain. Except for extra heavy tractors and a few other items, the British are rapidly increasing production of the machinery needed to supply their own requirements.

Some of the longer run questions and problems are: Is Britain turning her back on her old policy of being an industrial nation and buying foods in the cheapest world market? Is Britain overlooking the whole principle of comparative advantage? The answer to both questions is a weak and modified "yes." In the language of the report, "Unfortunately at the moment, food is not purchased with 'principles' of any kind; it takes dollars, pesos, francs, lire, kroner and the like. The recent war, world politics, current world economics and exchange difficulties have thrown our old friend 'comparative advantage' off balance. What to do *now* was a question that needed not only an answer but action as well. The British have answered by producing more because they couldn't at the moment buy more. They have also come up with a long time plan of producing still more. The plan is not rigid and, no doubt, will be subject to continual change."⁴

Few economists have found fault with the plan to increase the fluid milk, fresh eggs, potatoes, or even the 10 percent more beef, based on better pasture use. A good many, however, do raise questions about the extra four and one-half million tons of grain called for by the targets; a few also wonder how high incentives will have to go to gain the various production goals, and how much these floor prices and subsidies will cost if world food prices drop sharply.

*France*⁵

Before the war 85 percent of the food supplies of France was produced on French farms, and 70 percent of the imports came from overseas territories, mostly as fats, fruits, vegetables and feeds.

⁴ E. N. Holmgreen, *op. cit.*

⁵ Based on a report from K. J. Nicholson, Chief, Food and Agriculture Division, ECA Special Mission to France; and R. C. Desmond, Acting Agriculture Attache, American Embassy, Paris, March, 1949.

These supplies, together with wines and other alcoholic beverages, gave the French people an average caloric intake which was one of the highest in the world.

The war and a series of years of bad weather placed France's agriculture in a critical condition. Fertilizer was reduced, machinery was worn out from use or idle for lack of parts, horses decreased in numbers, fuel was not available for the few thousand operating tractors, and manpower was reduced. The drought of 1945, and the hard winter of 1947 followed by a summer drought, resulting in two of the worst crop years in a century, left France with a 200 gram bread ration and a total average consumption of only 2400 calories in 1947-48. Food was truly the major concern of everybody, furnishing part of the basis for continued black markets, inflation, political disturbances, and a heavy drain on national resources to keep the food situation in hand, even with very large imports from abroad.

During the first quarter of 1949, as a result of a very favorable crop in 1948, and continued help from abroad in the form of ECA aid, France appears to be slowly but constantly making progress on the road to recovery. However, the balance is still so sensitive that another poor crop or other economic setbacks could have very dire consequences.

Crop production in 1948 was 93 percent of prewar in relation to 80 percent in 1947, by far the largest part of the change being due to vastly improved weather. All types of livestock and poultry production are increasing materially. Individual rationing of bread has been dropped, prices of many agricultural commodities are easing, and black marketeering of food is disappearing. Significant surpluses of vegetables and potatoes have appeared. Major foods in short supply are milk, fats and meat, the first two still being rationed, but important improvement for all three is expected if feed grain imports are continued and another favorable crop year follows 1948.

ECA aid has had a large part in easing the food situation since it began operations. In the first few months this came in the form of bread grains to lift the bread ration from the low point it had reached in the early spring of 1948. Purchases of processed milk financed by ECA were intended to enable the French to meet the milk ration for children in the winter period of low production. Imports of vegetable oil-bearing materials and oils, that have

always been essential to the French economy were made possible by ECA. In the future, however, the means of increasing home food production will receive more emphasis than direct foods in the ECA program.

The ECA program in France operates within the framework of a four-year program and of yearly programs developed by the French Government as a member of OEEC (Organization for European Economic Cooperation). Present French plans call for increases of agricultural production by 25 percent above the rate of production in the second half of 1948. The increase is to be accomplished in part by an extension of the area in key crops, but largely by a sharp improvement in yields and a more intensive utilization of land resources. In particular, the yield of wheat is to be increased from a prewar average of 15 quintals per hectare to 20 quintals per hectare in 1952, and thousands of hectares now in pastures or natural meadows are to be converted to annual forage crops because of their higher yields. Total forage units available for feed, other than from straw, are to be increased by one-sixth.

In addition to a doubling of use of fertilizer, the program assumes that lime application by 1952-53 will have reached a rate five times that of 1938-39. Also, there is to be a rapid increase in supplies of tractors, other farm machinery and maintenance parts. A major program is planned to speed consolidation of small land parcels affecting two million of the 3.6 million hectares needing consolidation. A plan is also projected to regroup crops grown on the parcels not consolidated.

Further, the French program calls for the use of the principle of price guarantees to farmers as an inducement to necessary investment, and to the adoption of the improved techniques. In addition to investment by farmers from their own capital, large extensions of credit are to be made by the Government, and business firms serving agriculture are expected to invest heavily in the production and distribution facilities necessary.

The attainment of these goals would do much to solve France's problems. However, it is by no means certain that these goals can be attained within the period of ECA aid. In spite of the very favorable crop yields in 1948, first year performance is below the goals, and there are no indications yet that 1949 goals will be reached. Many of the parts of the program necessary to accomplish the goals are still in the planning stage, yet to be implemented.

The French have no adequate counterpart to the American action agencies administering programs to adjust individual farm production, to improve the facilities of production, or to supply farmers with the means of increased production and to demonstrate their best use. There are no county, community or individual farm goals, no county farm committees, no ACP payments, no government distribution of fertilizer, no Farm and Home Hour, and no soil conservation districts in France. Lacking personnel and funds, Departmental agricultural services are generally forced to limit their extension activities to a few demonstration plots and to speeches to farm groups. The major tool employed by the Government to adjust farm production in line with long-time needs is the guarantee of attractive prices for key crops, such as wheat, oil seeds, and sugar beets. Beyond this price support policy, governmental extension of credit, governmental encouragement of consolidation of parcels, and a few government subsidies for imported materials such as oil cake, custom largely determines what French farmers produce and the methods they employ.

For the economy as a whole, many major problems exist. France's most critical shortage is power. This results in a continued reliance upon manual labor and antiquated methods by American standards. This situation grows out of a long period of fear for their security as a nation and individual lack of confidence in the franc. Net investment was negative for many years. In agriculture it was retarded by lack of purchasing power prewar and a lack of materials in recent years. Those with francs want hard currencies or commodities which can be held or converted to cash easily as the changing value of the franc dictates.

As of March 1, 1949, prices were about 20 times prewar, with agricultural prices turning downward, while industrial prices show some indication of levelling off in face of increasing economic activity. Trade balances continue unfavorable, metropolitan exports to foreign countries being only 46 percent of imports from those countries in 1948. From this latter situation is created the principal question confronting all French planners, namely, how to earn more foreign exchange, particularly dollars, and how to obtain what is needed from abroad without having to pay for such imports in dollars. France, like the United Kingdom, is embarking on a major program of expanding home food production because she cannot sell enough abroad to take care of her food needs.

Italy⁶

The ECA program in Italy also has as its first objective increased production. This is to be accomplished by improving the unit yields and extending the productive cropping areas by reclamation, irrigation and land improvements; by shifts in land use to a more intensive agriculture and a higher utilization of the land and labor resources of the country; and by modernization of Italy's agriculture commensurate with her practical, physical and economic limitations. In addition the program is striving to raise the standard of rural living by providing roads, schools, utilities and houses in large areas woefully lacking in these facilities; and to broaden the base of land ownership to attain in a measure at least an improvement in the social problems which weigh so heavily on Italy.

Positive action on many fronts is directed toward fulfillment of these objectives, and the ECA program is used to accelerate the long-time trends. There will be a gradual shifting away from the over-emphasis on grain to a more intensive agriculture. Cattle will be gradually increased; the production of dairy products stepped up by herd improvement. Of particular interest is the good start which has been made in artificial insemination with 10 percent of the dairy cows already bred by this method. Vegetables and fruits will certainly be increased.

An extensive irrigation and reclamation program has been implemented under which three and a half million acres will be reclaimed and improved—and irrigation provided for 1,300,000 acres. Work is ready to start on many projects which will bring improvements in production as early as 1949. Work will be provided for 150,000 men for the next year. Production in dry farming areas will eventually be increased by 30 percent and on land where irrigation is provided, by 200 percent.

The implications of such a program are far-reaching. It means a great transformation of large areas now undeveloped. The gains will be not only economic but social. It will result in agriculture absorbing more people, important because over-population is a major problem. It is estimated that after the improvements are made there will be an average increase in employment from 40 work

⁶ Based on reports from Harry McClelland, Chief of Food and Agriculture Division, ECA Special Mission to Italy, Rome, February, 1949; and Howard R. Cottam, First Secretary of Embassy, and Robert A. Brand, American Embassy, Rome, February, 1949.

days per year per hectare in the dry farming areas, up to 200 work days per year per hectare on irrigated land.

Much of this work will be done in the south of Italy, in Sardinia and Sicily where the need is great. The ECA Mission has already examined in the field, prepared reports and submitted recommendations on twenty such districts. Plans are ready and work should start at once. The examination on the ground has been made in great detail by the Chief of the Division and by the Reclamation and Irrigation Specialist. Every canal, dam, road or flood control project has been passed upon—out of this has come a fine cooperation with the Italian government.

Another interesting development is the introduction in Italy for the first time of hybrid corn. Two thousand tons embracing 16 varieties of American hybrid, tested and found suitable for Italy, will be planted (last year 40 tons were used). The results obtained have been spectacular, with yield increase up to 86 percent over local varieties, with an over-all average well above 50 percent. For 1949 this should bring about an increase of 150,000 tons in corn production.

This represents the initial stage of a long range development which may culminate in Italy producing the hybrid seed corn for all of Europe. All of this is being done with direct assistance of ECA finances. When it is realized that over three million acres in Italy are planted to corn each year, the possibility of extending production of hybrid corn opens up new possibilities for livestock expansion and increased supplies for manufacturing.

Other experimental work along practical lines has been implemented by ECA. A top flight agronomist will study in the field the best way to adapt new crops to the great areas to be improved. Helicopters purchased with ECA dollars will be used to fight the dacus fly which does millions of dollars damage to the olive crop. ECA assistance is being given to rebuild a more vigorous extension service upon which will rest the sustained progress of Italian agriculture. Schools of instruction to farmers will bring to them for the first time some fundamental principles of new and modern husbandry and open up to them vistas of the new agriculture. A fund is provided to assist and help the individual make necessary improvements on his own farm; the small farmer will be helped to become an owner under current government plans.

ECA assistance given Italy in the form of large imports of foodstuffs, and increased domestic production has resulted in marked improvement in the food situation. Controls on all foods except a portion of cereals have been eliminated; that is, consumers are assured rations of 200 grams of bread and 100 grams of pasta per persons per day. Additional bread and pasta are available on the free market at prices only slightly higher than those of comparable rationed products. Foreseeable imports of breadgrains from the U.S., Argentina, and Iron-Curtain countries are sufficient to meet Italian consumption requirements until the new harvest.

One of the most important current problems of food distribution is the inadequacy of domestically produced fats and oils due to the very poor 1948-49 olive crop. The government has taken steps to solve this problem by contracting for 47,000 tons of edible fats and oils during the first half of 1949, in order to avoid the danger of price increases, particularly of olive oil.

The report from Italy closes with a thought common to most of the reports, "American agricultural economists may be interested to note that it is becoming increasingly evident that in the years to come Italy, and as a matter of fact all European countries, are going to buy where they can sell. That is axiomatic—and if the United States is to maintain its trade in agricultural commodities in a highly competitive market, it must revamp its trade policies to permit Italian goods freer movement. Otherwise Italy will look to the Argentine and to the East for her wheat and fats and oils and to other areas where Italian products are purchased."

*Bizonal Germany*⁷

The greatest problem facing Western German agriculture today is that of increasing production to provide for a refugee-expanded population 20 percent larger than prewar; and to offset as far as possible the loss of the highly productive areas east of the Oder-Neisse Line. This means a greater intensification of production, a shift to direct food crops with higher calorie yields per hectare, increased imports of fodder, and a limited production of livestock and livestock products for domestic consumption. It seems unlikely that the high prewar rate of consumption of meat, fat, and other

⁷ Based on a report from Paul Quintus, Bipartite Control Office; Food, Agriculture and Forestry Group, Frankfurt, Germany, March, 1949.

animal products will be achieved in the foreseeable future. On the contrary, the German diet will probably consist largely of cereal and vegetable products for an extended period.

Thus the agricultural policy aims not only at increasing production but developing a much more intensive type of farming and better crop rotation. The root crop area should be expanded considerably, and the area under pulses and oil crops is to be expanded, both as a means of soil improvement and to provide edible fat and oil cake for the cattle. These adjustments must be made at the expense of fodder grain and grasslands, however; a course of action squarely opposed by the farmers' strong determination to hold to the traditional farming pattern of livestock farming. It will be exceedingly difficult to keep livestock numbers in balance with available fodder supplies. So long as adequate fodder is imported the results need not be unfavorable. But if fodder imports are too small, home grown grains needed for direct human consumption will be fed to livestock and poultry. This is the reason every effort is being made to increase the availability of fodder grain and protein concentrates with ECA funds and through trade agreements.

ECA contributions to the bread grain program and direct fodder imports have greatly improved domestic butter production and have permitted an expanded hog raising program. In the first instance, better bread grain supplies have made it possible to lower the extraction rate for flour with increased milling residue for dairy cattle. This residue, oil cake from imported seeds, and imported feed concentrates coupled with a heavy crop of indigenous fodder during 1948 resulted in a sharp recovery in milk production this past winter. The combination of larger fat imports with ECA funds and stimulated domestic fat production have permitted an increase in the monthly fat ration for the normal consumer from 125 grams in March, 1948 to 750 grams in March, 1949.

A correlated problem facing agricultural planners in Western Germany is lack of the technically well-trained farm population necessary to maximize production. At present there are only six agricultural colleges in the Bizonal area, which has an estimated five million farm population. In June, 1948, these colleges had a combined enrollment of 2,700 student which was considered exceptionally large. The German agricultural education system is especially deficient in facilities for bringing the results of agricultural

research to farmers. A tentative request for 30 million dollars of ECA funds has been made as the minimum amount necessary for bringing about the desired improvement and expansion of agricultural teaching, extension and research facilities.

While most food and agriculture controls are still in effect in Western Germany a transitional period of relaxation and elimination of such controls is giving rise to new problems. A particularly serious problem which agricultural economists may be interested in watching is that of adjusting domestic agricultural prices to world price levels. For the fiscal year 1948-49, for example, it is estimated that wheat imported into Western Germany will cost \$109 or 363 DM per metric ton as compared with a domestic wheat price of approximately 250 DM per metric ton. Comparable prices for coarse grain are 283 DM per metric ton for imports and 190 DM for domestically produced coarse grain. In the case of sugar the situation is reversed, with imported sugar 370 DM per metric ton as compared with a fixed price of approximately 475 DM for domestically produced sugar. A decision will have to be made as to whether the prices of these and other commodities are to be permitted to rise or fall to world price levels, or whether they are to be controlled independently of world prices by means of subsidies, import duties, equalization schemes and other devices.

Although the direct expenditure of ECA funds in Bizonal Germany has been relatively small, this cannot be taken as a true measure of the role which ECA funds are playing in the recovery of Western Germany. It is largely due to the existence of these funds that the export trade of the Bizonal Area is able to finance urgently needed food imports.

Much of the gain from ECA activities is intangible and even psychological. In any case the export trade is rapidly climbing to a level which will enable Germany to finance to an ever increasing degree the food imports needed to maintain and improve a scale of nutrition which a year ago seemed out of reach.

Denmark³

In contrast with most other European countries, no major changes are contemplated in the pattern of Danish agricultural production in the long-term program. By and large the agricultural

³ Based on a report from George L. Peterson, Agricultural Officer, ECA Special Mission to Denmark, Copenhagen, February, 1949.

goal is to restore prewar production. The combined tonnage of milk, beef and veal, pork and bacon, eggs and poultry meat projected in the long-term program is approximately seven percent greater than prewar production.

Before the war, Denmark exported 83 percent of its butter, 66 percent of its bacon and 70 percent of its eggs. In order to export the largest possible volume, domestic consumption of butter, margarine and pork is held down by tight rationing. From a food standpoint, the Danes enjoyed a much higher standard of living during the war than now, because they could not export to England and they delivered as little as possible to Germany.

The end objective of Danish agriculture is to produce butter, bacon and eggs; all other agricultural production is of secondary importance or an intermediate step. To produce the maximum amount of butter, bacon and eggs, Denmark has always imported a large amount of feeds, mostly from dollar areas. Because these imports were not available during the war, cow numbers fell to 85 percent, pigs to 38 percent, and chickens to 38 percent of the prewar average.

In 1948 milk production was back to approximately 77 percent of prewar; butter production 66 percent of prewar, bacon and pork production 52 percent and eggs 79 percent of the prewar output. It is too early to measure the effects of imports of feed stuffs on the output of livestock products, but the number of cows at the end of 1948 was 63,000 above the same date in 1947, and pig numbers were roughly 500,000 more on December 31, 1948 than on July 1, 1948. A good 1948 harvest and the import of oil meals and oil seeds with ECA assistance account for increases in production.

In connection with imports of oil meals, however, a distinct effort is being made to reduce the amount of oil cake used in relation to prewar use. The use of coarse grains and silage from root tops is to be increased. The change is an effort to decrease the need for dollars for oil seeds and oil meal imports.

ECA assistance is particularly helpful in purchasing tractors and tractor machinery. Denmark is today in about the same stage of mechanization as the United States in the early 1930's. There are altogether too many horses for economical production. Before the war there were about 4,000 tractors; there are now between 8,000 and 10,000. As a result of imports of farm machinery the number of farm machinery stations—most of them private farmers

—who do custom work for the small farmers, almost doubled in 1948. There were 425 such stations at the last count. About 1,700 tractors from the U.S. will come in under the 1948-49 program and about 2,500 in the 1949-50 program.

A trend in Denmark's agricultural policy of particular interest to agricultural economists is the political pressure to increase the number of small farms (under 25 acres) at the expense of the larger farms. At present, Danish farms average 38 acres, the largest in Europe with the exception of England. As a result of legislation in 1899 and 1919 providing government assistance for the establishment of small holdings, the average size of Danish farms went down about $3\frac{1}{2}$ acres. At present, consolidation of two or more farms into a larger unit is prevented by law.

Another matter of particular interest is the dairy industry. There are in Denmark (16,600 square miles in area) approximately 1,600 dairy plants, of which somewhat more than 1,300 are cooperative. Most of the milk is delivered by horse and wagon. The management is aware that costs of production can be reduced by truck delivery to larger plants. It is intended over a period of years to reduce the number of creameries to somewhere between 300 and 400.

Restoration of trade is particularly important to Denmark. The United Kingdom is still the most important market for Danish butter, bacon and eggs, but substantial amounts have also been sold to Sweden, Russia, Belgium and Finland, and even 5,000 tons of butter to Canada. Prewar, 24 percent of Denmark's agriculture exports went to Germany, and restoration of that trade, particularly with the Bizonal area, is aimed at. Denmark would also like to export butter (primarily) cheese and pork products to the United States. Denmark must obtain dollars to purchase feed supplies (oil seeds or meal and coarse grains) which are available almost exclusively in the dollar areas. Unless she can export to the U.S. or the United Kingdom can provide convertibility, economic solvency by 1952 cannot be foreseen.

Belgium and Luxembourg⁹

Belgium and Luxembourg are returning to their prewar pattern of intensive farming, and this course is undoubtedly in line with long-time needs. ECA is making it possible to import sufficient

⁹ Based on a report from Jerome T. Gaspard, Agricultural Attache, American Embassy, Brussels, February, 1949.

foodstuffs for Belgium and Luxembourg to maintain their food consumption close to prewar levels. It has also made possible some very limited imports of agricultural machinery, and it is hoped that ECA will finance substantial imports of feedstuffs to make possible a restoration of prewar levels of production of livestock, dairy and poultry products.

In addition to continued good weather, the chief requirement of Belgian agriculture is the importation of sufficient supplies of feed grains. With the world grain shortage, world grain exports have been used almost wholly for human consumption, and Belgium has not found it possible to import normal feed supplies. As a result of the large 1948 corn crop in the U.S., the resumption of normal feed imports should soon be possible.

The most important problem facing Belgian and Luxembourg agriculture is that of making the necessary adjustments to meet the Dutch competition which will be felt under the Benelux Economic Union. Under the agreement of May 9, 1947, the three participating countries agreed that each country could limit its imports of agricultural products from its partners if the prices of such imports were below certain minima established by the respective countries. This agreement was specifically designed to prevent Dutch dumping of agricultural products in Belgium and Luxembourg. The Dutch costs of production are lower than those of Belgium and Luxembourg, and these two countries will be forced to take every possible measure to lower costs.

In this connection, there is no doubt that it would be desirable for Belgium to mechanize much more than it has to date, but several factors are operating to retard mechanization. There is currently considerable unemployment in Belgium and there is therefore no shortage of farm labor to create pressure for mechanization. In addition there is a tax on tractors, and a very high tax on gasoline. This high tax makes it economical for Belgian farmers to keep horses and oxen, which often eat up half the produce of small Belgian farms. According to the May 15, 1948 census, Belgium had only one tractor for every 100 farms.

The Belgian dairy industry requires considerable improvement at all stages: on the farm, in the processing plant, and in the distribution sector.

Although the Boerenbond (Farmers' League) has a highly developed extension service for its members, the extension service

of the Ministry of Agriculture is quite inadequate, and there is no effective means of passing on information from the agricultural colleges to the individual farmers. This is of particular importance in view of the Benelux Economic Union, and the highly effective Dutch extension service.

Despite the generally favorable economic situation there are disturbing factors: unemployment has risen to about 250,000 and prices are high, about four times the prewar level. It appears that 1949 will be for Belgium and Luxembourg a year of readjustment.

*Norway*¹⁰

Long-term agricultural plans in Norway worked out in connection with the ECA provide for increased efficiency in Norwegian agriculture. The program emphasizes crops best suited to the soils and climate, for instance the production of feed crops for the expansion of the dairy and sheep enterprises. It also stresses more pronounced grassland farming, with greater production of pasture and hay, and conservation in the form of grass silage, all to expand the production of animal products without too great imports of feed stuffs and concentrates.

Economic assistance to Norway by ECA has been of benefit to her agricultural program indirectly by financing raw materials and machinery imports required for reconstruction. This contributed to maintenance of full employment, which meant that the strong home market for farm products has been maintained. This maintenance of the home market may not be of greatest importance at present when the production of Norwegian farm products, mainly livestock products, is too small to satisfy the demand, but as production increases the maintenance of the home market becomes very important indeed.

As related to agriculture more specifically, Norway normally imports 80 percent of its bread grains, all of which have been financed by ECA since the beginning of the program. ECA has made it possible to import some concentrate feeds, even though the level of imports are still too low for full utilization of the productive capacity of Norwegian livestock.

There is a scarcity of agricultural labor, and the greatly increased cost of that labor creates an unprecedented demand for farm

¹⁰ Based on a report from Einar Jensen, Agricultural Attache, American Embassy, Norway, March, 1949

machinery. There is, for example, a considerable demand for tractors—and no production of tractors in Norway. Were it not for the ECA assistance, only British tractors, not heavy enough for many Norwegian conditions, could be imported. Thus, ECA has speeded up mechanization and helped to provide machinery better suited for Norwegian conditions.

Also as a result of the ECA program, many more agricultural scientists from Norway are going to the United States for study. After the isolation from other countries suffered during the war years, there is a great need for such study abroad, with all the stimulation of ideas and work it involves.

*Austria*¹¹

Austria, like Western Germany, has problems complicated by occupation. Austria is occupied by four powers, and food and agricultural supplies were furnished by the four occupation powers, by UNRRA, by Congressional aid and by interim aid, before the start of the ECA program. The big difference that can be noticed under the ECA program is the emphasis upon the rehabilitation phases of the food and agriculture policy, as compared to the dominance of relief assistance under the previous programs.

Livestock enterprises, especially the heavy grain-consuming hogs and poultry, suffered great decreases during and following the war because of complete lack of imports of feed stuffs and continued droughts. Under the ECA program feed supplies are being imported into Austria to supplement the increased production of 1948, so that livestock may be increased.

Long-time objectives for Austrian agriculture emphasize livestock—especially dairy cattle, which can effectively utilize the areas primarily adapted to grass production. The rough terrain and heavy rainfall makes many of the areas especially adapted to grass production.

Heavy applications of fertilizer are badly needed for both grass and crop areas. Phosphate and potash fertilizers are being imported under the ECA program in as large quantities as the farmers are able to buy. Likewise, supplies of seeds and other items necessary for increased production are being imported in quantities.

One of the big problems in carrying out the expanded agricultural

¹¹ Based on a report by W. S. Middaugh, Food and Agricultural Office, ECA Special Mission to Austria, and coordinated with Agricultural Attache.

program in Austria is price relationships. Great emphasis has been placed on price stability, and price-wage agreements between labor and the other elements of the economy have been reached only after protracted discussions, with agreement coming at about harvest time, rather than before planting time, which would be desirable to stimulate increased production. This lack of forward-looking price and the general philosophy that the agricultural sector of the economy fared well during the war and should now make sacrifices in order to maintain price stability, has meant that the agricultural production program has not had the desired impetus, and has not gone ahead as fast as would have been possible under more favorable circumstances.

Turkey¹²

Turkey's problem is also one of increasing production, not for home consumption, however, but for export. Turkey is at present self-sufficient in agriculture commodities and they have in the past made up approximately 90 percent of her exports.

The long-time agricultural program calls for increase in production of cereal crops, cotton, oil seeds, pulses, livestock and livestock products, and others. However, little or no consideration has been given to the development of the program from a standpoint of land use or over-all planning. It has been developed mainly commodity-by-commodity and there is need for a well-balanced agricultural mission from other countries to review the plan before it is finally adopted.

Turkey has only slightly over 6,000 farms that are 125 acres or more in size (with the exception of 13 large state-operated farms). In spite of this, 85 percent of the population is engaged in agriculture. Most of the farms are very small and crops are raised with nothing but hand tools. Very crude plows, many made of wood, and little or no equipment, insecticides, fungicides, are used on Turkish farms. Anything that can be obtained under the ECA program that will make it possible to improve tillage, plant crops at the proper time, prevent disease and destroy insects, and harvest and store crops properly, will materially increase total production and augment exports.

The ECA program, if carried out as planned, should increase

¹² Based on a report from Charles R. Enlow, Agricultural Attache, American Embassy, Ankara, February, 1949

production tremendously, particularly in an undeveloped area of virgin wheat land of several million acres. Tractors and farm machinery are being obtained under ECA to develop this area. There are now 13 state-operated farms of approximately 700,000 acres in this area that have been in operation from three to four years. These farms have proved conclusively that the production of wheat and other crops by dry land farming is not only possible but practical. One of these farms, about 70 miles from Ankara, in a 17-inch rainfall belt, had 26,000 acres of wheat last year that produced 35 bushels per acre.

There is also a large acreage in Turkey suitable for gravity irrigation, and other extensive areas that show possibilities for pump irrigation. Turkey is a country of winter rainfall and any irrigation that can be carried out increases production tremendously. Under the ECA program, Turkey hopes to acquire well-drilling equipment, irrigation pumps, assistance in constructing dams, and technical assistance.

The problems in Turkey of primary interest to agricultural economists are principally the possibilities of increased trade. Turkey has many products including strategic minerals that are in demand in the United States, and production can be greatly increased. As far as agricultural products are concerned, the main problem is for the Turks to improve the quality of the products and establish a name for their goods. If these things can be done, it will be possible for Turkey to increase her exports to the United States and narrow the gap between her imports and exports.

NOTES

RELATION OF METHOD OF ACQUIRING FARM TO PRODUCTION FACTORS IN COTTON FARMING

SINCE the war increasing attention has been given to the problem of maintaining the continuity of farm operation between generations. It is an issue that has vexed land economists in this country for some decades because farm tenancy and scale of operations are involved. The thought has been that if farms can be passed on to the next generation systematically, the benefiting son or son-in-law would be attracted to farming as an economic opportunity at a comparatively early age. This would tend to reduce absentee landlordism and therefore tenancy. From the standpoint of economy of operation, farms passed on intact avoid parcellation and a size, layout and location generally uneconomic to operate. Furthermore if the farm passes to the next generation anti-mortem, considerable decline in productivity of the farm may be avoided.

Although there are many variations, the central theme of these experiment station bulletins and extension circulars has been the advocacy of a father-son arrangement by which the two would operate the farm jointly until the death or retirement of the elder man, when the farm would pass by inheritance according to previous agreement wholly or in part to the younger man. These are well meaning intentions but certain relationships which have turned up in a recent study¹ suggest that, if the same findings hold true for other segments of the agricultural economy, such an arrangement may mean less to agriculture than generally believed.

The farms in the study referred to were obtained by conventional sampling methods from 9 counties² in the Upper Piedmont of South Carolina and Georgia. In all 988 farms were obtained in this region³ but only 624 farms had a production history of sufficient

¹ The study referred to, still in process of analysis, is a cooperative study of cotton yield variability between the University of Virginia and the Bureau of Agricultural Economics, Division of Agricultural Finance, Ralph R. Botts and E. Lloyd Barber, collaborators. Acknowledgment is made to the General Education Board for a grant in support of the project.

² Greenville and Pickens counties, South Carolina, Carroll, Clarke, Cobb, Douglas, Haralson, Jackson, and Madison counties, Georgia.

³ A second sample of about 750 farms was obtained from West Texas but the data are not yet in a sufficiently advanced stage of analysis to make a similar study of inheritance as here described.

TABLE 1. COMPARISON OF SPECIFIED OPERATOR CHARACTERISTICS, PRODUCTION FACTORS, AND YIELD AND YIELD VARIABILITY DATA ACCORDING TO METHOD OF ACQUIRING FARM

(Based on 376 white owner-operators, males, from the Upper Piedmont)

Items	Farms reporting 3 or more years of yields, 1938-46	
	Acquired by inheritance ^a	Acquired by purchase
Number of farms	59	317
Average acres of cotton harvested	15.6	16.3
Operator's characteristics:		
1. Years of schooling	8.3	7.5
2. Age in 1946	53	55
3. Experience growing cotton on 1946 farm	24	18
4. Percentage of operators engaging in off-farm work in 1946	33	27
Farm practices for period (3 or more years between 1938 and 1946):		
1. Average fertilizer applied (in 100 lbs)	4.9	5.2
2. Ratio of legume acreage harvested to cotton acreage	0.88	0.84
3. Percent of cropland in cotton	26	26
Percentage of farms in 1946 in severe erosion class ^b	30	22
Percentage of operators reporting:		
1. Farms operated with cropper labor primarily	36	27
2. Seed cleaned and/or treated regularly prior to planting	54	65
Farms reporting 3 or more years of yields, 1938-46		
1. Average yield	304	332
2. Average coefficient of variation	27	27
Farms reporting 8 or 9 years of yields, 1938-46.		
1. Number of farms	32	157
2. Average yield	313	351
3. Average coefficient of variation	27	25
4. Trend in yield, lbs. yearly	3.6	6.3

^a Farms were considered as inherited if over 50 percent of the existing 1946 farm was so acquired.

^b Based on judgment of enumerator, who was generally an employee of the county AAA office.

duration to give 3 or more years of yields. Comparative data according to two methods of acquiring farms for a homogeneous class of owner-operators are given in Table 1.

The data show that the operators of purchased farms, 317 in all, obtained 28 pounds more of lint cotton per acre for an average of 3 or more years during 1938-46 than those operators (59) who inherited their farms; there was no significant difference in variability of yield for the period. Increasing the number of years included in the yield average improved further the margin in

favor of the operators of purchased farms. Among the farmers in this group who purchased the farm which they were operating in 1946, 157 reported 8 or 9 years of yields in the 9-year period from 1938 to 1946. There were 32 comparable farms which had been inherited by their operators. As shown in the table the operators of purchased farms averaged 38 pounds or 12 percent more of lint cotton per acre during this longer period than did the operators of inherited farms, and had 7 percent less yield risk as measured by the Coefficient of Variation. Furthermore, the former were improving their yields at a more rapid pace than the latter, the yearly upward trend averaging 6.3 pounds as compared to 3.6 pounds of lint per acre.

Further examination of the data shows wherein the operators of purchased farms were superior and inferior to those of inherited farms. It is apparent they are not greatly superior in the production factors, certainly not sufficiently so to explain the yield differentials. Although a higher percentage of the inheritors occupy more severely eroded farms the differences are not great otherwise. The purchasers used 30 pounds of fertilizer more per acre and had a somewhat better record as regards treating and cleaning of planting seed but again these factors, and even taking into account the somewhat less erosion, probably are not sufficient to account for the higher average yield of those farmers who purchased, especially when the favorable factors of more education and younger average age of the inheritors are taken into account. Some of the difference must be due to entrepreneurial ability and conditions under which the two classes of farms are operated.

The conditions under which farms are acquired by inheritance may be, for analytical purposes, divided into two major categories—those left in the natural course of events to the non-resident child, and those farms left as consideration for the child's having remained on the farm.

Farms may pass by inheritance to city relatives or to farmers of the same type who live in the community or on an adjoining farm. In the former case the inherited farm would as a rule be operated as a tenant farm, and the effects on yields and yield risk would be those of typical tenant-operated farms with uncertain tenure. On the other hand, if the heir resides in the community, or on an adjoining farm, he would have the familiarity and interest in farming as a profession to capitalize on his good fortune. Such

farms would be expected to show up more favorably in yield and yield risk than other classes of farms.

Where the farm is bequeathed as a reward for the child's remaining on the farm, although the factor of interest can be reasonably assumed, the operator is more probably of lower inherent entrepreneurial ability and less maturely developed in the little he has than the typical owner-operator who purchased his farm with money saved or raised through some financial institution. While the purchased farm reflects the owner-operator's likes and judgment in its selection, the inherited farm shows neither. Obviously, those who inherit farms through this sequence of events would be expected to be less bold and energetic than their brothers who acquired land by other means, or left the business of farming altogether to find city employment. Furthermore, their entrepreneurial development would be hindered by the domination of the older generation, which would often prevent them from reflecting the alertness and progressiveness of their age in farm operation. On these farms this means that by the time the father passes out of the picture, the younger man often will have passed his physical prime and have become set in the ways and methods of a generation once removed.

Among the 59 inherited farms included in the analysis 18 operators had acquired considerable experience on the farm inherited prior to becoming its operator, 41 had not. The operators with experience on the farm prior to inheritance averaged 40 pounds or 13 percent less lint cotton per acre than the operators reporting no previous experience on the inherited farm. There was no significant difference in yield risk, but considering only those farms with 8 or 9 years of yields during the period, it is found that the inheritors with previous experience on the inherited farm had on the average a downward trend in yield of 4 pounds of lint cotton annually in contrast with an upward trend in yield of 6 pounds yearly by the inheritors with no previous experience on the inherited farm.

Although the number of operators with previous farming experience on the inherited farm is somewhat small for the significance desired, the results afford considerable support for the thesis, advanced above, that the son who remains on the farm with his father is more likely to be low in certain entrepreneurial abilities and have less chance for development of them than the son who strikes out on his own.

These relationships may not be applicable to those types of farming where a very high order of intellectual ability is required, and where frequent and important changes of technique occur. Both conditions would tend to produce progressive entrepreneurs in both generations. Also, irrespective of type the operators of large farms may and frequently would be sufficiently progressive to give the heir selected a free hand and to create opportunities for his entrepreneurial development. The author of this article is informed, however, that a very large Mississippi Delta plantation operator recently requested an only son upon his graduation from college to seek employment elsewhere until the farmer's certain retirement when the latter would return and take full control. The entrepreneur in question obtained his farm the hard way and is one of the most successful farmers in the Delta. He apparently is convinced that two lights shine less sharply together than either alone.

Certainly, maintaining continuity of operation between generations is quite desirable and a worthy objective if it can be accomplished without lowering the quality of farm operators and reducing the general level of efficiency of the agricultural economy as a whole. It seems necessary, however, if the above results are found to prevail in the other major segments of agriculture, that the second generation come into the picture as completely as possible in every respect. But such is not in accord with the traditions of American agriculture. The older generation insists upon staying in the picture and too frequently in a cramping and often dominating position, so that there's confusion as to who is in charge and hesitancy, delays, and half-measures in the control and in the making of progressive changes. What is needed is an effective retirement system which will get the older generation off the feet of the younger generation. In general retirement is not within the reach economically of the vast majority of farmers. But extending the Old-age and Survivors Insurance benefits of the Social Security program to farmers would help. Even this plan would not be completely successful because of the very modest scale of benefits. It would be more successful, however, if some plan could be devised by which a part or all of the retiring farmer's equity could be recovered and joined with the Social Security benefits in the form of an annuity for the remainder of his life and that of his spouse when she survives. If coupled with a farm or village housing plan which

would enable retirement to the place of their choice, either on the home farm at non-interfering distance from the farmstead or in a favorite nearby village, the aged in agriculture would have not only security to look forward to but also comfort and independence, while agriculture would have an efficient and sensible solution to a troublesome problem, one which along with many other factors keeps the industry working at less than its maximum efficiency.

ACCURACY OF LIVESTOCK PRICE FORECASTS AT KANSAS STATE COLLEGE

MONTH-to-month forecasts of livestock and grain prices have been made by staff members of the Department of Economics and Sociology of Kansas State College since 1925. These forecasts appear monthly in a printed publication entitled "The Kansas Agricultural Situation."

Difficulties in Measuring Livestock Price Forecasts

The principal difficulty confronting an analyst who attempts to measure the accuracy of a monthly price forecast is the lack of a standardized terminology to describe accurately the three dimensional variables of direction, timing and magnitude of price change. Such terms as "higher," "stronger," "steady to moderately higher," do not permit accurate statistical measurement.

The forecasting of livestock prices is not an exact mathematical science. Although analysis of historical, statistical data plays a prominent part in forecasting, such a procedure usually serves to give the forecaster only a rough indication of the effects of the various measurable factors influencing livestock prices, rather than to provide a definite answer regarding the exact price to expect.

Once the forecaster has determined the importance which he should attach to the various statistical indices, the problem of forecasting becomes that of keeping abreast of new or unusual developments in the commercial, political, and agricultural situation, and then properly evaluating the effect which these developments will have on price.

Method of Determining Accuracy of the Forecasts

Since an important element of uncertainty in the measuring of the accuracy of these forecasts was the determination of a quantitative meaning to be attached to the various terms used in stating the forecasts, an arbitrary statement, based on estimates of men engaged in making the forecasts, was prepared.

In preparing this score table (Table 1) it was decided that it would be illogical to hold the forecaster to an exact percentage

TABLE 1. SCORE TABLE FOR MEASURING ACCURACY OF PRICE FORECASTS

Forecast	100 percent	Score 66 percent	33 percent
	Percent change in price		
Substantially higher	5% or over	4% or over	3% or over
Higher	4% or over	3% or over	2% or over
Moderately higher	3 to 7	2% or over	1% or over
Slightly higher	2 to 6	1 to 7	0 or over
Steady to higher	1 to 5	0 to 6	-1 to 7
Steady to moderately higher	0 to 4	-1 to 5	-2 to 6
Steady to slightly higher	-1 to 3	-2 to 4	-3 to 5
Steady	-2 to 2	-3 to 3	-4 to 4
Steady to slightly lower	-3 to 1	-4 to 2	-5 to 3
Steady to moderately lower	-4 to 0	-5 to 1	-6 to 2
Steady to lower	-5 to -1	-6 to 0	-7 to 1
Slightly lower	-6 to -2	-7 to -1	0 or lower
Moderately lower	-7 to -3	-3 or lower	-1 or lower
Lower	-4 or lower	-3 or lower	-2 or lower
Substantially lower	-5 or lower	-4 or lower	-3 or lower

change for the meaning of each term, and in view of this a rating table was constructed which allows a certain range in the meaning of each forecasting term.

Each month's forecast was scored on the basis of the actual price movement during three ten-day periods of the month. The object in dividing each month into these three periods was to allow some credit for a forecast which may have been correct the first ten or middle ten days of the thirty-day period for which these forecasts are made, but which became inaccurate during the latter part of the month. Since these forecasts are intended to extend over a thirty-day period, and since more credit should be given for a forecast that was accurate throughout the entire month, an arbitrary weight of one was assigned to the score of the first ten-day period, two to the second, and three to the third. The later periods of the month were thus more heavily weighted. Having determined

the percent price change represented by each forecasting term, and the weight to be assigned to the accuracy for each ten-day period of the month, it was a simple procedure to score the accuracy of the monthly forecasts. Having scored each ten-day period, the weighted scores were averaged for each month, and a yearly average taken.

Accuracy of Hog Price Forecasts

During the period 1925-40, hog price forecasts made at Kansas State College averaged 64 percent correct.

A study of the seasonal variation of the scores of the actual forecasts shows a distinct seasonality in the accuracy of the predictions. The least accurate months were August (47 percent) and April (50 percent). The month during which the forecasts were most accurate was November, scoring 77 percent.

It was recognized that the arbitrary scoring table and the varying weights would affect the score obtained. Therefore, the calculated score was measured against a score obtained by using the average seasonal price variation as the only basis of the forecast. This forecast was based on the average seasonal price movement for 200-250 pound good-to-choice fat hogs at Kansas City during the period 1922-38. The average accuracy of the forecast based only on the seasonal price variation was 37 percent. This indicates that the hog price movement during an individual year differed considerably from the average seasonal pattern.

Having obtained the scores on both the actual forecasts and the forecast based on seasonal price variation, it was then possible to calculate an index which would show the extent to which the effects of factors other than the average seasonal price movement had been correctly estimated. On the basis of this index it was found that the actual hog price forecasts averaged 72 percent more accurate than the forecasts obtained by using only the seasonal price movement.

The objective evaluation of the hog price forecasts indicated an average accuracy of 64 percent. The forecasts were more useful than the score indicates. When these forecasts are scored only on the basis of whether or not they indicated the general direction in which the price moved, a somewhat better result is obtained, the forecast being accurate 69 percent of the time.

For purposes of comparison, a study was made of the accuracy that would have resulted if the forecast had been based on a

continuance of the trend as indicated by the previous thirty-day period. When the previous thirty-day period was used as the basis for forecasting an accuracy of 56 percent was obtained.

Accuracy of Cattle Price Forecasts

During the sixteen-year period cattle price forecasts made at Kansas State College averaged 62.7 percent accurate, ranging from a low of 37 percent accurate in 1931 to a high of 94 percent in 1929.

The seasonal variation in the accuracy of cattle price forecasts did not exhibit as great a degree of variance as did that of hog price forecasts. However, there was a general tendency for the forecasts to be more accurate during the late winter months and again during June, July, and August.

Using the average seasonal variation in the price of choice 700-1,100 pound steers at Kansas City 1922-38 as the basis for forecasting price, an average accuracy of 52.7 percent was obtained. During the months of April, August, and October the actual price changes most nearly corresponded to the change which would be expected from the average seasonal price movement. The actual forecasts made were 23.6 percent more accurate than those based only on the average seasonal price movement.

When the forecasts were rated in regard to their accuracy in predicting the general direction in which the price would move, it was found that they were accurate 68 percent of the time. When the trend during the previous thirty-day period was used as the basis for the forecast, an equal degree of accuracy was obtained. Thus it would appear that the general direction in which the price has been moving would be one of the most important factors to consider in formulating a price forecast for cattle.

Effect of Magnitude of Price Change upon Accuracy of Forecasts

The price forecasts made appeared to be most accurate during those periods in which there was little change in price and least accurate when the change was great. The hog price forecasts ranged in accuracy from 72 percent when there was no change in price during the thirty-day period to 59 percent when there was a great change in price. Cattle price forecasts ranged from 68 percent accurate during periods of no change to 57 percent during periods of great change.

RATE OF COMMODITY DISAPPEARANCE AND CONSUMER PREFERENCE

BECAUSE of the augmented program of research in marketing, many agricultural economists in the United States are finding themselves involved in the fields of psychology and statistics to a greater extent than formerly. Although these two fields are far from being unrelated, the former deals more with logical classifications of mental concepts and resulting human behavior, while statistical methods are the tools and devices for measuring the intensities and interactions of these concepts and the probabilities of repetition of behavior.

Terminology in the field of consumer preference is confusing. As one travels around the United States he hears people express desires in such terms as *like*, *fond*, or *love*. It is entirely possible that the housewife who at her bridge club "just loves" the cake from a certain recipe "likes" it at home if she is sincere. This makes it difficult to measure people's opinions by their verbal expressions. At any rate, a survey of people's opinions as to how they "feel" about subjective matters may be entirely fruitless unless it is carefully planned both from the standpoint of statistics and psychology. A physician might probe a patient's abdomen and ask whether it hurts "much." If the patient has a subjective concept in which significantly less pain than exists in the mind of the physician means "much" he may pay for an unnecessary appendectomy, whereas if the reverse were true he may die for lack of necessary surgery. A better method would be to probe the general region of pain asking the patient to describe the degree of pain and plot directions of trends of increasing pain in order to localize the point of greatest pain. The points would thus be plotted in terms of the patient's own scale of subjectivity instead of the patient's compared with the physician's. Subjectivity can not be a constant even within one mind, but it will come closer there than if its interpretation must be conveyed to another mind. It should be borne in mind in consumer opinion surveys that the responses, unless manifested by measurable action, are entirely subjective and can be measured only in terms of this subjectivity. Measurement can best be carried out by finding out what a person's choice would be out of two or more alternatives and get the verbal expression of choice in the chooser's own relative and superlative terms.

There is a large gap of unrealism between a consumer opinion survey and what the consumer actually would do if the conditions assumed in the question actually existed as freedom for real choices. It is not uncommon to hear people say, "I would give my right arm for that." Although it is merely a figure of speech it means a very high price in their minds. A high price is stated because they are sure the commodity is not on the market. People are not willing to tax their mental energies beyond rather loose opinions and evaluations unless their energies are to bear fruit in reality. It is thus ordinarily more difficult to analyze and derive valid conclusions from statistics of opinion than statistics of behavior.

Those specializing in opinion surveys are making progress in correlating loose opinions and evaluations with real behavior despite indications of serious reversals. For many purposes, what people say they will do when a condition presents itself is the best index (adjusted by former correlations) of what they will actually do. However, the correlation between opinion and action can never be perfect, so, if the individual can be observed under experiments setting up actual conditions the results will be more reliable. Both consumer opinions and instances of behavior are imperfect manifestations of preference but it is probable that behavior is a better basis for predicting preferences. On this basis, consumer preference should not be determined from opinion if it can be determined from observed behavior at the same time and cost.

In experiments on consumers' preferences a procedure not entirely unknown to the vendor has been used. The plan has been to offer the consumers two or more choices and to shift the prices to affect the rates of purchases. When these prices have not moved goods at the relative rates desired by the merchant he has, as a result of previous experience, hunches, or trial and error, shifted the prices more. Having found his errors too great he puts on his "clearance sale." Those commodities that have in his estimation moved too slowly are reduced in price. Actually they then sell for less than they would have if they had been priced competitively with other commodities at a normal rather than an accelerated rate of disappearance.

The merchant may choose arbitrary rates at which he wishes different commodities or different grades or qualities to disappear from his shelves. In general, the limits of his arbitrariness are set only by his capacity to lose money. The researcher should not

choose arbitrary rates. He can not assume as the merchant ordinarily does that for his purposes there is an unlimited supply of the several choices. In some of the experimental work on consumer preference, an error has been made by arbitrarily assuming that the proper preference was at the price differential that would make the choices disappear at equal rates. There are preferences that should be based on equal rates, as for example the choice of pre-packaging one way or another or handling in bulk, but in cases where the supplies of the choices are interrelated this should not be the case—unless, of course, if they are interrelated in such manner that the supplies are equal.

There are those in the field of agricultural economics who look upon themselves as the "hired men of agriculture." How meritorious this attitude is depends primarily on whether these economists are concerned with efficiency problems or with problems of individual or group equities and whether they are privately or publicly employed. In marketing problems involving equities the public researcher or administrator needs to guard against becoming the pleader for or against segments of society. In order to take an unbiased or indifferent attitude toward group equities in marketing research, and if marketing researchers vested with a public interest are to enjoy the influence accredited to scientists this must be done, it will be necessary to have a clear-the-market concept in controlled experiments studying consumer preference. The rates of disappearance must then be guided by this concept. This is something that can not be fixed immediately and for the long run because the relative production of choices normally varies and will vary again when and if the results of research in consumer preference become influential on the market. The degree to which there will be variation will depend on the differences in the elasticity of the supply of the several choices. An equilibrium should be established by the price structure so that it will not be necessary to have "clearance sales" for any of the choices tested. Unless the clear-the-market concept is a guiding criterion there will be a tendency on the part of the researcher in marketing inadvertently to fall into the trap of scarcity economics. It would then become a problem of finding out what volume and type of supply would bring the greatest net returns to agriculture despite negative effects on the rest of the economy. Action of this type would soon make a syndicated political issue out of the marketing research program. The attitude must

be taken that agricultural economists in public institutions and agencies are hired men of the public.

Merely to have reached an equilibrium between consumer choices is not always carrying the research far enough for an accurate test. Take as a hypothetical example a comparison of selling apples in boxes or baskets. Conceivably all apples could be sold either way, so it would be logical to assume that when equal volumes are moving in each of boxes and baskets the price differential is then correct. Some studies that should have been carried further have stopped at this point. In this situation the price differential would be correct only while the two alternatives existed. It would not follow that *all* the apples could be moved equally well in either method. If half of the apples disappeared in boxes and half in baskets it might be true that each customer had reached a "zone of indifference" as to which he would buy. This, however, would be extremely unlikely. It would also be possible that the experiment had segregated from the others those consumers who want apples in boxes rather than baskets, or conversely, and price was not a factor. This also would be unlikely and the probable situation would be somewhere between these two extremes, The incidence of this probability needs to be tested.

When the equilibrium of rates of disappearance has been found through the pricing mechanism the next thing to do is to *withdraw one choice* at a time alternately and see what happens to the remaining rates. If, by chance, the total volume of trade remains the same regardless of which choice is withdrawn, then the "zone of indifference" represents the general indifference of the consuming population. If the volume of trade falls for either choice there has been segregation of consumers and it would not be safe to say that it makes no difference, in this example, whether apples are sold in boxes at a certain price or in baskets at a certain price. Whether a choice should be maintained depends on the effect on the sales volume not only of the choices in question but also on other "lines" offered to the same customers.

For many purposes of prediction it would be desirable to analyze facts concerning the consumers who indicated their preferences both in the equilibrium period and at the periods of alternately withdrawn choices. Analysis of them should serve as a guide in setting up questionnaires for interviewing consumers. In general it is better to predict preference from instances of behavior but these

may be related to facts pertaining to consumers. It is also more valuable to obtain information that is less changeable even though the information might deal in the realm of opinion. For example, it would be more important to get church affiliation than it would political affiliation or perhaps even than how the consumer actually voted. Factors of importance in stratifying the consumer population, so that a more reliable expansion might be made from the sample of consumers whose behavior has been observed, might be found through the process of alternately withdrawing choices.

In some studies the fact that people need time to orient or condition themselves to a new idea has been overlooked. Suppose an entirely new type of choice is to be offered to consumers. It might then be more important to measure an acceptance trend over enough time to prove that adoption of the choice would or would not be economical. In research this trend could be studied as a byproduct of the method of alternate withdrawal of choices.

MARKET AND MARKETING RESEARCH IN THE MIDWEST

EACH state is doing work in these fields. Regional projects are set up in connection with livestock, milk, eggs, potatoes, fruits and vegetables, and poultry (technological). In some cases regional funds are used to expand work on local problems with little or no attempt to coordinate the efforts in a solution of a regional problem. There is need for a much more thorough and well thought out over-all program as to the basic problems in each field. It is recognized that effective research is done by competent individuals working often on rather small problems. But it is also desirable that these individual problems fit into a comprehensive plan.

Basic problems may be classified: (1) the market, (2) the organization of the marketing system in performing its functions effectively and efficiently; (3) the organization of individual firms in performing their particular jobs efficiently and effectively; and (4) the development and application of improved technology.

1. *The market*—This term is used to mean the quantitative and price aspects of an economy's sales of a particular good. We are concerned with the farm products and the products derived from

them in the 12 midwest states. Basically, we start in this area with grains, oilseeds, and forage crops as the major farming pattern with fruits, vegetables, tobacco, etc., as minor products for the region as a whole. In 1946 we converted these major products into animal products or sold directly as follows, in billions of dollars:

Meat animals	\$4.6	Feed crops (chiefly corn)	\$1.1
Dairy products	1.9	Food grain (chiefly wheat)	1.0
Poultry products	1.2	Oil-bearing crops	0.5

We need to know in detail all the factors which affect the market for these products and their principal subdivisions, e.g., cattle, fluid milk. By market we mean quantity and price considerations. The problem may be divided:

a. *General economic relationships*.—Price quantity relationships, income effects, distribution-of-income effects, general price level effect, competitive relationships, secular tendencies in relative demands, etc.

Much work has been done in this field, but much of it is now out of date. One can also criticize much of it as market research for undue attention to one phase of the problem viz, with price-supply relationships when the facts faced in the market are changes in the general price level, or with consumer incomes in the USA when the controlling factor may be a change in the international position.

b. *Market areas*.—To study the market one must know the size of the market area involved. This may be local or regional as for fluid milk; national as for beef; international as for wheat. An international market does not mean the whole world but only the areas in which the United States can actually sell. One must define the market area and its characteristics. For example, all our beef is sold within the United States but the market area for a particular class or grade of beef may be more localized.

c. *Market development*.—Consumer tastes change; new technology permits a product to be sold in a different form. These developments may be of minor importance to producers, as for example, a new pie crust mixture (which may be very important to the competitive position of a particular firm), or they may be very important. Important historical examples are refrigerator cars, vegetable shortening, and the rise in consumption of fluid milk. Economists should be alert to these developments and should be steadily evaluating them as they may affect situations in (a) and (b)

above. Thus the rise of vegetable shortenings apparently altered the demands for lard and refrigeration certainly changed the market areas for all perishable products.

The increased use of products in higher economic categories as consumer demands develop for them is in the interest of both producer and consumer. Some examples:

(1) Many consumers want better eggs than they can currently buy. Prevailing premium prices are evidence. The problem here is to develop marketing facilities which will act as the needed link between producer and consumer so as to satisfy adequately this market demand.

(2) Using dried skim milk as a food is a higher order of use than feeding it to livestock. Not only technology but effective merchandising efforts are necessary to develop this use.

(3) On a broader scale shifting milk from manufactured to human use moves milk up to a higher category of use. Much of the reorganization in the country end of the dairy industry over a long period of years has been in response to this fundamental shift in market outlet.

Many other illustrations might be given. The basic point is that market research should aim at searching out any undeveloped market outlets which will shift products to a higher category of use. To effectuate the changes, much marketing research may be needed.

When the use of a product increases (other than in response to population growth) adverse effects are likely for competing products. So market research must also be alert to developments tending to push certain commodities down the scale of use.

2. *The organization of a marketing system.*—Between the producer and consumer is a complicated marketing system. For simplicity we include in this system all agencies in the area whether they perform merchandising, transportation, processing, or other functions. For different groups of commodities the details of the system vary although in each case it performs broadly similar functions. However, for convenience in research the various commodity systems can best be studied individually but always in the light of the general principles common to all.

“What functions must a market system perform?” and “How effectively and efficiently does it perform them?” are key questions.

Some important functions will be briefly mentioned. Filling in the details of a particular system and measuring its efficiency are problems for specialized research.

a. *Pricing functions.*—The most important function of any marketing system is pricing at every level of the system where title to goods is transferred. It is by response to prices that consumers register their opinions as to their relative demands for different kinds of goods. It is by prices that the basic market factors—supply and demand—are balanced. Evaluating the system of pricing should be the first object of systematic marketing research. Certain criteria of efficiency need to be set up and each system studied to see how well these criteria are met.¹

After such an examination, one is in position to make suggestions for changes. Much research in milk marketing has centered on this problem. Formulas to guide public agencies in setting milk prices have been evolved. Some of them have broken down because the functions which prices must perform in a market were not clearly understood or the formulas did not allow for factors which would cause prices to vary so as to perform their functions.

The failure to provide a supply of the quality needed to satisfy a high level of demand may indicate a pricing system which does not reflect this demand back to producers. The University of Illinois research in egg marketing was set up to study this question.

A part of a pricing system is a system of market standards. Without such standards prices have no specific meaning. In analyzing the pricing system one should examine how well the standards in use really reflect the differences which users, either intermediate or final, really desire.

These illustrations point up the fact that evaluation of the marketing system should begin with the pricing functions.

b. *Risk functions.*—Investments in facilities or commodities create risks at every level of marketing. Risks are costs which must be covered if the people are to do certain jobs. Marketing systems develop ways of providing for these risks. It may simply be a wide margin or mark-up which will cover the risk involved. Fruit and vegetable markets illustrate this method. It may be the evolution of very large firms with large capital resources and stable retail price policies, as in tobacco. It may be the development of special market institutions for hedging as in the grain, cotton, egg, and butter markets. In any analysis of the marketing system these

¹ For a tentative list of such criteria see L. J. Norton, *The Effectiveness of Market Mechanism for Adjusting Farming to Public Need*, Proceedings of the Sixth International Conference of Agricultural Economists, pp. 113–115, Oxford University Press, 1948.

particular devices need to be studied and evaluated. The existence of risk is a primary cause for the entrance of governments into the marketing field. The various systems of supporting minimum prices that have been evolved should be included in any comprehensive study of risk.

c. *Physical functions*.—In moving goods from producers to consumers many physical jobs are needed: assembling, transporting, processing, storing, distributing, display, etc. Marketing research in agricultural products has perhaps dealt too much with these rather than with the more fundamental pricing and risk functions. The logical order of analysis is (1) to determine the jobs to be done and (2) to study the system to find out the kind of firms developed to do them. A careful analysis may find that some link in the process is unnecessary or that some other type of agency can do it more effectively. The actual patterns are constantly changing. The researcher should discover these changes. He should evolve a standard which will permit him to evaluate them and when adequately qualified, even to suggest changes. Cases in point over the last 30 years are:

(1) The development of larger units in food retailing with all kinds of foods in one store often associated with the combining of retail and wholesale functions.

(2) The shift to paper containers in milk distribution with accompanying increased sales of milk in retail stores.

(3) The decentralization of the livestock market particularly for hogs.

Other students may wish to analyze the marketing system in terms of more than these three major functions. However, our general division into pricing, risk carrying, and physical functions will be found useful.

3. *The organization of individual firms*.—The marketing system is made up of a very large number of individual firms, some large and some small. For any analysis of detailed operating problems, the firm is the basic unit of study. However, in a logical program of research a systematic knowledge of the market and the marketing system should precede studies involving individual firms. In getting answers about the market or the system we must often, of course, use data from firms.

Work with individual firms may be of the following kinds:

a. Development of basic data as standards to measure efficiency in performing different functions.

b. Analysis of specific practices in particular firms, especially those which are introducing new methods.

Since the big costs of marketing are in retailing, work in this field should emphasize studies in that area.

4. *Technological research.*—Many marketing problems can only be solved by technological research. Some of this may reach back into the area of production. Examples are: Retail store sales of milk are based on the paper container. Marketing ripper peaches apparently depends on a solution of the "brown rot" problem. Marketing better sweet corn depends on development of practical and economical methods to precool it at or close to the farms. Strengthening the competitive position of lard in comparison with the shortenings rests on development and promotion of more stable lards. The economist can point out problems based on market research and should be aware of technological changes and be in position to evaluate their effect marketwise.

Technological research by public agencies ought to be directed toward problems of general application rather than at specific problems of particular firms. A highly specialized product may be very important to the competitive position of a particular firm but such research on it can best be done in the firm's own laboratories. The paper milk bottle and the problem of stabilizing lard are examples of generalized technological research.

SUMMARY OF PRACTICES AND PROCEDURE IN TEACHING MARKETING OF FARM PRODUCTS

IN assembling material which might be helpful in discussing the problem "Methods of Teaching in Agricultural Economics" to be used at one of the roundtable programs at Green Lake in the autumn of 1948, a questionnaire covering certain phases of teaching methods and practices was prepared and sent to all the land grant college departments of agricultural economics or marketing. Forty states returned reports. Their replies may be briefly summarized as follows:

A. General

SAMPLING MEDICAL SERVICE CHARGES: A NEW APPLICATION OF SAMPLING METHOD

THE use of the "parity price" measure in the administration of government programs relating to farms and farmers places a heavy responsibility upon the agency which constructs the index numbers of prices farmers pay for the commodities they buy.

Since 1911, when the U. S. Department of Agriculture started to gather data on prices paid by farm families, there has been a continuous effort to develop such data and to use appropriate statistical procedures for obtaining and analyzing them and in constructing the index of prices paid.

Within the Department of Agriculture, the responsibility for gathering and summarizing the data that are used for computing the index of prices paid by farmers has been placed upon the Bureau of Agricultural Economics. The number of items on which price data are available has been expanded from time to time and at present most of the principal categories of farm family expenditures for commodities are represented in the index of prices paid. However, there are several types of services bought by farmers that are not in the index, and for which adequate data are not yet available. Medical service is one of the more noteworthy of these groups.

Expenditures for medical care are an important element in the farm family budget and this has long been recognized. A survey covering 1941, made by the Bureau of Human Nutrition and Home Economics of the U. S. Department of Agriculture, indicated that the families of farm operators spend annually about \$370,000,000 for medical care, medicines, and drugs. This was nearly \$60 per farm family, or 7 per cent of the average farm family budget.

In 1936, data on the fees charged for office calls and associated medical services were obtained by agents of the Bureau of Agricultural Economics in 19 states, covering the periods 1910-14, 1924-29, 1932, and 1935-36. Since then, the Department has not had the funds nor the personnel for collecting similar data on an annual basis. After the end of World War II, the Department has again investigated the problem of getting the information needed in the construction of annual index numbers of prices paid by farm families for medical services.

Measuring medical expenditures by farm families presents a number of difficulties. Many of these difficulties are inherent in

the nature of the expenditure patterns themselves. Heavy expenditures are often unplanned and arise from an accident or emergency operation. Broadly speaking, there are two general approaches to the subject. The first concerns surveying the farm families directly; the second would deal with doctors, dentists, hospitals, etc. that serve farm families. The technical design of sample surveys for either of these two broad groups is very difficult to work out. However, largely because of the variation in type and amount of medical care among farm families, it is believed that this question can best be approached through inquiries to hospitals and the medical profession. A survey plan was devised for Maryland and tests were made in that state to test the adequacy of the sampling procedures used and the workability of the schedules and methods.

The sample in the Maryland survey was designed for obtaining information by interviewing physicians, surgeons, dentists, hospital officials, oculists, and optometrists that would yield data from which state estimates could be made of the rates paid by farm families for selected types of general medical service. If such a survey were extended to a sufficient number of other states, data would become available for computing indexes of the percentage changes in the prices paid by farm families for all medical care.

In conducting the sample survey in Maryland, questionnaires were prepared for each selected type of medical service. Physicians and surgeons were asked to report the most common fees charged families for the ordinary types of services rendered. The questionnaire for dentists asked for charges to farm families for filling, cleaning, X-raying, and extracting of teeth. Hospitals, serving farm families, were asked to report on the cost of hospital rooms, salaries of registered and practical nurses, as well as charges for other common hospital services. Oculists and optometrists were asked the fees most commonly paid by farm families for eye glasses.

A separate sample was designed and used for each of the four types of questionnaires, (1) Physicians and surgeons, (2) Hospitals and nurses, (3) Dentists, (4) Oculists and optometrists. The basic pattern of the sample for each of the four surveys, however, was determined by the sample used for the Physicians and Surgeons Inquiry which therefore is discussed first and in more detail.

The 1942 Directory of Physicians and Surgeons of the American

Medical Association was used as a basis for selecting doctors to be included in making the survey. The first step was to eliminate, by using the medical directory, all doctors who limited their practice to special fields or excluded farm families in their practice, and also to eliminate physicians and surgeons practicing in the large industrial cities where the Bureau of Labor Statistics gathers similar information on medical services. The intention was to include in the universe of inquiry only those doctors who provided farm families with general medical care. Thus, from the medical directory a list of about 650 physicians and surgeons was obtained which satisfied this criterion of providing general medical care to farm families in Maryland.

This list of 650 doctors was arranged alphabetically by towns and by counties for each agricultural price reporting district in Maryland. Next the list was divided into two sections. The first section consisted of doctors in towns which had two or more physicians or surgeons, and the second section of the list consisted of doctors who were in towns which had only one physician or surgeon. It seemed necessary to make this separation because a slightly different sampling ratio was needed for each situation in order to represent adequately the state as a whole. The goal was to obtain about an 8 percent sample of doctors serving farm families and at least 50 reports as the minimum number needed for reliable state estimates. Actually a somewhat greater number of doctors' names was selected in order to compensate for the inability of interviewers to reach some doctors and to allow for refusals to answer. The sample ratio was computed by dividing 60 (the number of names desired) by the total list of 650 doctors previously selected. On this basis every eleventh physician or surgeon on the list was to be selected for interview. This sampling ratio was applied directly to the sub-list of doctors practicing in towns having only one physician or surgeon. The fifth name was selected and every eleventh name thereafter was chosen to be interviewed in the doctor survey.

In selecting doctors to be interviewed from the sub-list of those practicing in towns which had more than one doctor serving the farm public, it was necessary to modify this procedure somewhat in order to minimize travel and to assure that average fees obtained would represent the particular towns randomly chosen by the sample. A restriction was imposed that at least two doctors in each town selected should be included in the sample. The procedure

was to choose the eleventh name on the list and the one below it as a starting place. Thereafter every twenty-second name was chosen along with the next following name. Rules were adopted which assured that two doctors having separate practices would be selected in each town surveyed. The addresses of the doctors selected for interview automatically determined the towns which formed the basic sample for the surveys on other medical charges.

The sample for the hospital, dentist, oculist, and optometrist surveys was determined by the towns selected in the doctor's sample. Where a choice was to be made within the pre-selected town, the names of dentists, oculists, and optometrists were selected at random from the classified section of the telephone book. Data were also obtained from all general hospitals in the towns covered by the doctor's survey. The size of the sample in each town was made equal to the number interviewed in the doctor's survey. The interviews were conducted by a statistician from the Maryland State Office of the Agricultural Estimating Service at College Park and a statistician from the Bureau of Agricultural Economics working together.

Survey results indicate that in Maryland the rates charged farm families for medical service have not advanced so rapidly during recent years as have prices paid for most other items used by farm families for living purposes. The preliminary results in Maryland gave a 1947 index number of 164 percent of the 1910-14 base period, previously mentioned.

This survey did not attempt to measure the extent to which such services are used by farm families, but recent investigations by the Bureau of Human Nutrition and Home Economics indicate that farm families are having increased medical care. Moreover, doctors interviewed in this survey in Maryland said that farm families at that time had more money to spend on medical care than they did a few years ago, and that collections from farm families on bills had recently been above average.

Analysis of the results of the survey indicates that this sampling procedure may be expected to produce satisfactory data from which state estimates of the prices paid for individual services may be made, for use in the construction of an annual index number representing medical services.

Agricultural Statistician, Minnesota

BOOK REVIEWS

Joint Committee Report on Extension Programs, Policies and Goals,
U. S. Government Printing Office, Washington, D. C. August
1948. Pp. 72.

This is a report of a Joint Committee of ten, five appointed by the U. S. Department of Agriculture and five by the Association of Land-Grant Colleges and Universities in October 1946, with the following general objectives: (1) Appraise the services and experiences of the Cooperative Extension Service over the years; (2) study the important basic problems of cooperative extension work, particularly relationships with the U. S. Department of Agriculture and Land-Grant Colleges; and (3) develop definite recommendations as to how the Cooperative Extension Service can best meet the problems of the future.

The accomplishments of extension work during the one-third of a century of its operation are summarized in the first section of the ten-section report. The primary function of extension work in agriculture and home economics is education, and the report emphasizes this point. The proper performance of this function requires use of an increasing number of techniques in an ever widening range of subject matter. This entire section is a very modest but sound statement of the achievements of extension work. The section concludes with this significant statement: "In short, whereas extension has done much for people, it is what extension has helped people do for themselves that achieves the greatest results."

There is danger that this broader function—helping people learn to help themselves—learning how to solve their own problems—may be overlooked too frequently. The specific improved operating practices which can be appraised in terms of immediate and tangible results on the farm crowd out this broader objective. Moreover, there is a growing obligation to help farm people understand the complex social and economic problems—local, national, and international—that face them. It is in this field of work that so many agents, particularly the older agents, have the most difficulty. Many have difficulty developing and maintaining a well-balanced and complete service in their counties. A much more comprehensive program is needed today than was provided in the early years of extension work.

The Committee makes five specific recommendations regarding the relationships between the United States Department of Agriculture and the land-grant colleges and universities in connection with extension work: (1) To keep mutually informed on new developments quarterly meetings should be held between representatives of the Department and the Association of Land-Grant Colleges and Universities; (2) annual meetings should be held between the Secretary of Agriculture and an appropriate committee of the Association; (3) the Department and the colleges should reach agreements on responsibilities *before* new Department programs are launched which involve education in the States, (4) Department agreements with other State agencies involving education should be worked out in conjunction with the colleges; and (5) the Department and the colleges should give greater assistance in training State extension workers.

The Committee feels that despite some difficulties experienced in recent years in operating under the "Memorandum of Understanding" of 1914, the Memorandum is nevertheless an adequate statement regarding cooperative relationships between the Department and the State colleges in conducting cooperative extension work. If adhered to, all educational programs within the State for which the Department has a responsibility will be carried on through, or in cooperation with, the State colleges.

The perennial problem of the proper relationships of the Extension Service with general farm organizations is discussed in Section Four. The Committee concludes that, although close cooperation with general farm organizations is highly desirable, former operating relationships with such organizations are detrimental to the public interest. It specifically recommends that all legal connections and exclusive operating arrangements between farm bureaus and the Extension Service be discontinued, and that Extension Service officials and farm bureau leaders in the States concerned take the initiative in this matter. A dissenting opinion by one member of the Committee is also included in the report covering this point.

The Committee recommends full coordination of the three college functions—resident teaching, research, and extension. It believes responsibility for such coordination should be placed under one administrative head, and that each subject-matter program of the three should be combined into one department. This reviewer believes this is a sound recommendation, but realizes such coordina-

tion is far from achieved in many land-grant colleges for one reason or another.

The Committee believes that while subject-matter specialists are of great value to extension work, the specialized approach can, and frequently is, over-emphasized. In appraising the trends and outlook for extension, the Committee lists the following as the effects of technological progress: (1) A need for more knowledge of the use and maintenance of machinery; (2) an increase in the capital required for efficient farming and rural living; (3) a widening of the gap between efficient and inefficient farmers, and the resulting displacement of farm labor; (4) increased production, and hence need for greater emphasis on soil conservation and on marketing distribution; and (5) continuous changes in the home, with new opportunities and new problems for the homemaker. Other trends of particular importance to extension in the future are: (1) The need for rapid expansion in the field of conservation of natural resources; (2) the need for expanding emphasis on individual farm and home planning; and (3) the decreasing number of farm families and the increasing number of rural nonfarm families; and (4) the continued need for, and emphasis on, better rural health and rural educational services.

The Committee concludes that the present need for extension education among farm people is apparently far ahead of the capacity of extension to meet it, and that this should be a great stimulus to extension efforts. It calls for a careful sifting of demands and effective allocation of time and effort. Particularly great is the need for the extension type of informal, continuing educational programs. Extension's goal should be to maximize efforts on education, and guard against any tendency to become largely an emergency or administrative agency.

This Joint Committee report is an excellent statement of extension programs, policies, and goals. It should be read by every staff member of our land-grant colleges and universities. If the recommendations contained in the report are carried out effectively, extension can certainly expect a growing need for its services in the years ahead, and be confident that the Nation will profit greatly from its services.

Montana State College

Rural Mexico, Nathan L. Whetten. Chicago. University of Chicago Press, 1948, Pp. xix, 671, XXIII Plates, Statistical Appendix, and Index. \$10.00. Foreword by Manuel Gamio.

Rural Mexico is a scholarly work devoted to the understanding of the land of the author's birth. Professor Whetten, now of the University of Connecticut, spent his childhood in Mexico. This investigation was made possible by his appointment for three years as a member of our Embassy staff in Mexico City. One gets the impression that Professor Whetten has written with two sets of readers in mind, the Mexicans and ourselves. The result is an extremely well balanced book which ranks with the previous landmarks of analysis and interpretation of Mexico by our scholars: as, Simpson's *Ejido*, Tannenbaum's *Mexican Agrarian Revolution* and McBride's *Land Systems of Mexico*.

The study is divided into four major parts: population and geography, the relation of the people to the land, standards and levels of living and social institutions. A vast amount of information is included in the 91 tables in the text and the appendix of 41 tables. Professor Whetten has included a digest of the major published statistics on rural Mexico plus numerous presentations from hitherto unpublished data. The 20 page bibliography provides an excellent guide to the literature in both Spanish and English. Especially in his treatment of land tenure, the author uses a comprehensive review of previous studies to state the problem for his own work. The statistics on the results of the land reform program include the data for 1945. Throughout the study, one finds the insight that can come only to one who has travelled to the remote valleys and visited with countless people in their own tongues.

Rural Mexico is not only a competent study; it is an important one. It has great significance just because Mexico is beset with so many of the difficulties and problems that plague the world today. This era is undoubtedly the most revolutionary one of recorded history. No one can foresee the end but the Mexican Revolution of 1910 may well be considered marking the beginning of this series of social upheavals. Mexico is a vast laboratory of this violent age; a few of the more significant facts may be noted.

The Mexican Revolution antedated both the Russian Revolution and World War I; it was not a planned revolution at all, as Whetten points out so clearly. But once the people were aroused by the prospect of "Land and Liberty"—the old order was doomed.

The most dramatic and fundamental part of this revolution has been the confiscation of large estates and the re-distribution of land. This is only the beginning of social reconstruction; but the "fat is in the fire" as we say. One can argue the pros and cons of the Mexican land revolution, and Whetten presents the evidence and arguments with impartiality, but most of the arguments about whether or not the revolution improved conditions are simply comments after the fact. Efficiency of resource use is not a major question during a revolution, partly because property and security of expectations are demolished thereby, and partly because deeper issues are at stake, such as equitable distribution and human dignity and freedom. A comprehension of the Mexican Revolution is a valuable object lesson to all of us interested in rural and human welfare, not because revolutions are something to be desired, but because revolutions break out when no other methods of meeting human needs and aspirations have been devised.

Twenty-three percent of all the crop land in Mexico has been re-distributed by the land reform program. Allotments have been given to 1.7 million persons out of a total population of 20 millions. Although we have heard much more about the grants to communities, the ejidos, the land reform program also resulted in a great increase in small individual holdings. Among the 1.2 million private holdings in 1940 about three-fourths were of less than 5 hectares (about 12.5 acres). Fifty-seven percent of the land holdings were on the ejidos. It is interesting to note that the land reform program was conceived initially as a way of giving workers a small plot of land upon which to live that they might earn most of their living from employment near-by. But the torrent once loosed cut through the very structure of land ownership, tearing great haciendas to pieces. Most of the ejidos are operated in tiny pieces with the individuals holding the rights to use specific pieces of land. Those fragments are not farmed well; for the most part these people have few tools and only the most primitive knowledge of farming. But the eighth of the ejidos farmed collectively have their troubles too, since the farming operations must be done by joint action. Students of farm management will find this part of Whetten's analysis especially interesting. If one compares these operations with those on the Russian collectives, he will be impressed by the strenuous efforts at democratic procedures in Mexico, even though an elected foreman makes a very poor boss.

Social reconstruction is complicated in Mexico, and in many of the other Latin-American countries by the "Indian question." The 1940 census of Mexico was taken in 50 tongues. Spanish and 49 Indian dialects. Our own country was "settled" by Europeans; Latin America was "conquered." The result was a feudal structure in which the Indians were slow to learn the language of their conquerors, furthermore the ideals of private property and individualism which sparked the liberation of European serfs had little relevance to the social life of the indigenous population. These are some of the consequences of conquest which remain in Latin America today. This conflict of cultures makes the problems and prospects of rural development in the Latin Americas more difficult, in many ways, than in the Middle East and Far East. In these latter areas poor peasants share the same culture with the more fortunate people.

It is hard for us to comprehend the poverty which still exists in Mexico. Two-thirds of the people are farmers of some sort. Forty-five percent of the people were classified as living in huts by the last census. Many of the so-called houses were little better, without chimneys or any other conveniences. Forty percent of the people have no beds, either sleeping on the dirt floors or on little platforms. Few people have access to good drinking water. About one in four have no shoes. Once this is realized it is easier to comprehend that an Indian is someone who lives like an Indian; i.e. in abject poverty. One can cease to be an Indian by putting on shoes and assuming some of the other characteristics of the upper classes.

One is tempted to say that all the dilemmas of economic progress in backward economies are found in Mexico. Where an agrarian revolution occurs, the peasants getting a small piece of land are most likely to grow something to eat. They eat better even though total agricultural production decreases. In a country like Japan this creates a food crisis in cities. In a country like Hungary this creates a crisis in international trade, as wheat for export is not forthcoming. In Mexico, a self-sufficient peasantry grows corn everywhere; this is the mainstay of their diet and the core of their natural economy of subsistence. Whetten's analysis of diets is illuminating and gives a commendable orientation for land utilization studies in backward economies. In the background of this study lurk all the thorny questions of economic development. How can food production keep pace of the increase in population? How can

a country become industrialized, so that the standard of living can rise? How can the needed capital be secured, where there is so little margin for savings?

The answers to those tremendous questions are not clear in Mexico. Furthermore, the projection of such questions upon a world plane make the answers still more difficult. Surely the solution all over the world cannot be to industrialize and purchase the needed food. It is the recognition of this fact which is making Neo-Malthusians out of so many people these days.

But if the answers aren't clear in Mexico, at least the way is now open for thoughtful consideration of the ways out. The ground has been cleared. The fate and hopes of the country seem to hinge on the possibility that the revolution may eventually energize the people in a way that a feudal society never could. In Whetten's concluding words: "The personal freedom enjoyed by the general population is probably the greatest achievement of the Mexican Revolution. In the long run, this may prove important enough to counterbalance whatever mistakes may have been made."

K. H. PARSONS

University of Wisconsin

Plowshares Into Swords, Arthur P. Chew, New York: Harper and Brothers, 1948. pp. xv, 221. \$3.00.

The thesis presented in this book is that wars are caused by an unbalance between agriculture and industry. Industrial nations (except the United States) have access to food only by exchanging industrial products with agricultural exporting countries. But agricultural countries are industrializing themselves. In the process, tariffs and trade barriers are raised against the industrial countries. As a result, industrial countries are forced into imperialism in efforts to annex agricultural areas and re-establish the balance between agriculture and industry within their own borders. They beat plowshares into swords because "they have an overwhelming need for plows or more literally, for agriculture; it is for agricultural resources that they go to war."

This argument is developed in its various aspects in the first eleven chapters. A number of topics are discussed. Agricultural self-sufficiency is fostered in industrial countries as their export trade declines. The relation of population growth and world conflict is discussed. Here the author emphasizes the rapid growth in Euro-

pean population and the resulting top-heavy industrial structure. He quotes the early Veblen on war with approval and disagrees with Veblen's later views that the masses of the people have no interest or gains from imperialism. In his discussion of declining populations he suggests that reductions in the working population will complicate the problem of food procurement by lowering the production of those industrial goods that can be traded for food. No tables and few statistics are given.

In later chapters he discusses the position of the United States with high industrial tariffs and subsequent efforts of American farmers to develop a price system providing comparable benefits to agriculture. He deals with the separation of industrial Europe from agricultural America. In chapter XVI the author discusses export dumping, appearing to accept the idea as a necessary means of keeping the economic wheels turning. He does not discuss the possible repercussions in other nations. He deals with conservation and immigration as possible partial solutions of the agricultural-industrial imbalance. Finally he proposes two immediate alternatives and one long time solution to the problem.

The first solution is a system of much freer trading which he rejects as being politically impossible. The second alternative is world effort to provide forbearance in industrialization by agricultural countries and to provide security of food imports to the industrial countries. While the exact implementation is not specified, it might take the form of a series of industrial commodity agreements whereby industrial countries are provided guaranteed sales of their output. It is difficult to see much real difference between the two programs. The long run solution is an urban-rural balance within national boundaries all over the world, attained by industrializing agricultural countries and developing agriculture in industrial countries or by coalescing nations together.

Much of the discussion in the book is a somewhat different version of the have and have-not nation theories prevalent before World War II, couched in agricultural rather than raw material terms. This reviewer sees little justification for changing the terms of the argument. Coal, iron ore or oil may be considered far more vital than food in some nations.

Another phase of the argument that seems weak is that there is a limited demand for industrial products. He argues that as an agricultural nation builds textile mills, steel mills, machinery plants,

etc., its purchases of industrial products inevitably decline. There is no recognition of the possibility of increasing the sales for other types of industrial goods and advancing the level of living to satisfy an entirely new order of human wants. Of course, two world wars and a major depression have not furnished a favorable economic climate for developing real experience along these lines.

The problem of economic relations and world peace obviously is important. The role of the United States in leading the way in adjusting the conditions and terms of trade is clearly shown both in regard to trade barriers and price support policies. Mr. Chew proposes the difficult road of controlling the development of new competitive industrialization, and eventual uniform balance between agriculture and industry within each country. This would eliminate a large part of the gains from specialization and trade. This reviewer believes that there is more to be gained and still some hope of success in revising our actual trade policies to conform with our theoretical trade policies.

LAWRENCE W. WITT

Michigan State College

A Survey of Contemporary Economics edited by Howard S. Ellis. Philadelphia: The Blakiston Company, 1948. Pp. 472. \$4.75.

A Survey of Contemporary Economics is an attempt on the part of "specialists" to review and appraise the developments which have taken place in their respective fields, during the past "ten or fifteen years." The impetus for the compilation and publication of these reviews was supplied by the American Economic Association's committee on the development of economic thinking and information. The recent developments in each of the foremost areas of specialization within the field of economics have been summarized by a competent authority and his appraisal in turn has benefited from the criticisms of two qualified and able critics. In the words of the editor the purpose of the volume "... is to provide the economist outside a particular field an intelligible and reliable account of its main ideas—both analytical devices and their practical application to public policy—which have evolved during the last ten or fifteen years."

In Chapter 1 Bernard Haley summarizes the developments which have taken place in the area of value and distribution. Much of this section is concerned with the impact of the indifference curve

approach on the theory of demand and with reporting a number of empirical studies bearing on the supply side. Haley's comments are more in the nature of summarization than of interpretation and appraisal.

Much of the discussion in Chapter 2 on employment and business cycle theory and in later chapters on monetary theory constitutes an attempt to fit the torrent of ideas and controversies unleashed by Keynes into the evolution of economic thought. Indeed, the doctrines of Keynes intrude at some point into nearly all of the resumes which are presented in the volume. Viewed in the aggregate these discussions seem to the writer to indicate that much mastication and perhaps regurgitation of the Keynesian concepts and their implications lie ahead before they can be regarded as thoroughly and finally digested.

In a lucid discussion of monopoly and the concentration of economic power, J. K. Galbraith traces the impact of the work of Joan Robinson and Edward H. Chamberlain on economic analysis. He concludes that the most important contribution of these two noteworthy books was "to emancipate the analysis of markets from the inadequate categories of competition and single firm monopoly." But in appraising the results of 15 years of renewed effort to unravel the problems surrounding monopolistic enterprises and to evolve a public policy adequate to cope with them, Galbraith concludes, "It is apparent that although the increment of knowledge has been considerable, both tasks have been attended by considerable frustration. The analytical task would appear to have failed because oligopoly by all evidence the ruling market form in the modern economy has not yielded to the kit of tools long employed for the analysis of the competitive market. . . . It is the essence of the oligopoly solution that any individual can effect the solution. The analysis therefore had to take on a wholly unmanageable burden of assumptions as to how each participant in the market would behave."

Wassily Leontief's review of the work of the econometricians should be welcomed by the non-mathematician who has found himself puzzled by their manipulations. Leontief explains that the function of statistical analysis in application to econometric research is "that of an intermediary between a general theoretical hypothesis and the directly observable facts." He suggests that the outstanding developments of the last years lie primarily in the realm of methodology rather than in the direction of factual analysis, and then adds

"certain signs seem to indicate that this phase is now drawing to its close and that the years immediately ahead will witness new accomplishments in fields of applied studies."

The book ends with a peppery and thought provoking summary by David McCord Wright on the prospects for capitalism. If after dwelling through much of the book upon the seemingly overwhelming problems confronting our "capitalistic" system one is led to despair of its future, Wright does a masterful job of dispelling the gloom. He states that he cannot see that capitalism is suffering from any basic functional weaknesses in the sense of immutable laws preventing it from working. While he agrees that capitalism's future depends upon intelligent policy, Wright concludes, "It is difficult to escape the conclusion that under the present conditions capitalism, economically speaking, once more makes sense. In the light of world conditions what we need now is saving and production, and what can do a better job in these respects than capitalism?"

The science of economics, like the intricate economy whose functioning it seeks to analyze, has sought a "gain in product from the division of labor." But if it is to be fruitful exchange must accompany specialization. One can reasonably doubt that there has been a sufficient exchange of ideas among those working in the highly specialized areas within economics. Because they are without exception remarkably intelligible, considering the complex analyses they treat, these surveys are particularly well fitted to facilitate such an exchange of thought. *A Survey of Contemporary Economics* should be especially useful to the agricultural economist interested in catching up on what those working in other branches of economics have to offer.

RAYMOND R. BENEKE

Iowa State College

Conservation in the United States, A. F. Gustafson, G. H. Guise, W. J. Hamilton, Jr. and H. Ries (Cornell University). Comstock Publishing Co., Ithaca, N. Y., 3d edition, 1949.

Conservation in the United States is the third edition of a textbook that was first published ten years ago. It describes the extent and use of our natural resources, and as the title implies, gives particular attention to future supply-demand relationships. The book is interestingly written, well-organized with a good index, and enlivened by more than 250 maps, charts, and illustrations. Many of the pho-

tographs were taken by the authors and contribute to the impression that this book is a personal account of the conclusions reached after many years of study and observation.

Following a brief introduction and a chapter devoted to the development of conservation movements in this country, the book is divided into four sections written, apparently, by the four authors in the order in which they are listed on the title page. The first section deals with soil and water resources; the second with forests, parks, and grazing lands; the third with fish and wildlife; and the last with mineral resources. The chapters pertaining to soil resources describe the geologic origin of soils, the distribution of soil types in the United States and the related types of farming, the nature and extent of soil depletion and erosion, and the various methods and programs for soil conservation. In a general way, this treatment of soil resources characterizes the discussion of the other resources as well. In each case, the authors present an inventory of the resource, the uses for which it is valuable, the extent of its depletion, and the possibilities for its conservation. The result is a book adapted for general use in college-level courses in land economics or resource conservation.

The principal shortcomings of this book are those of omission. In its 512 pages—approximately 100 pages more than in the first edition—the authors discuss a great variety of subjects, frequently in some detail. As a consequence, certain topics are not treated as fully as some readers may expect. The 21 pages devoted to western range resources, for instance, contrast with the 41 pages describing fish and fisheries, and the 52 pages relating to game, fur, and other wildlife resources. Little or no attention has been given to such land-use programs as the submarginal land purchase and resettlement programs, rural zoning, land-use planning, and the AAA incentive programs for soil improvement. There is no discussion of land as space, or of the land requirements for transportation and urban uses.

The authors are primarily interested in the physical aspects of resource utilization, but it would seem that a discussion of conservation requires more than passing reference to property rights. Arid-region water resources, for instance, are adequately represented as a scarce and valuable resource, but little attention is given to the elaborate legal doctrines by which those resources are allocated, used, and conserved. Comprehensive treatment of conservation

also seems to demand some mention of our most important resource—people—and the resource problems resulting from population growth and distribution.

By treating the various natural resources successively and independently, the authors have avoided—and failed to answer—some of the most troublesome questions of conservation. By one definition at least, conservation is a rationing process involving a choice between dissimilar alternatives. Within limits it is not possible to save one resource without increasing the burden on others. This book competently demonstrates that we should preserve our soil, water, trees, and minerals, but it does not indicate how we are to warm our homes without using coal, fuel wood, natural gas, petroleum, or some other natural resource. In discussing the destruction of agricultural land in strip-mined areas, the authors come close to disagreement because they are considering soil resources in one context and minerals in another (p. 168 f., and p. 434). The fact that “best land use” implies alternative possibilities which must somehow be weighed and compared by a common standard of evaluation is inadequately acknowledged.

An economist will note that this entire book on conservation makes only casual reference to the economics of resource utilization. In discussing forestry, for instance, there is no mention of the time required to produce a timber crop, or the compounding of interest, taxes, and other costs with which a forest owner must reckon, or the various reforms in forest taxation which have attempted to make timber growing economically feasible. The possibility of conserving forests—or any other resource—will often depend on such economic considerations, or upon the fact of public ownership, public expenditure, or police power regulation. These elements are no less important than physical and technological factors in determining the use and conservation of our natural resources.

C. W. LOOMER

University of Wisconsin

Forest Farming and Rural Employment, Charles H. Stoddard, Washington, Charles Lathrop Pack Forestry Foundation, 1949, Pp. 29.

Forest farming has been suggested at various times as a means of (1) increasing total timber production, (2) securing better forest

management on private lands, and (3) providing employment for rural people. This study presents an excellent analysis of the opportunities for and the limitations of forest farming.

The forest farm is defined as "a unit of land and timber with a combination of tillable land, forest growing stock, and capital equipment sufficient to sustain full-time employment with forestry as the major activity, for one family, with a minimum of two men of working age. A full-time forest farm would provide two men 250 days of forest work a year with subsistence farming incidental thereto."

It is estimated that a full-time family-type forest farm would require an annual cut of about 500 cords or 330,000 board feet of logs where the workers cut, skid and haul the timber. Where the workers do not skid or haul their cut timber, an annual cut of 750 cords or 500,000 board feet is required. If a sawmill is operated in conjunction with the logging enterprise, an annual output of 150,000 to 200,000 board feet will provide two men with full employment. These production requirements necessitate minimum forest farm areas of 1,000 to 2,000 acres (800 to 1,500 acres if a sawmill is operated) in the northern Lake States and areas about a third less than this size in the South. Estimated capital requirements for a full-time forest farm range from \$25,000 to \$70,000.

The author's analysis is based largely on case studies made in northwestern Wisconsin and in southwestern Arkansas. He uses these data to indicate that forest work provides a promising source of rural employment. He also examines the financial possibilities for successful forest farming in these areas and finds that it can be a profitable business. At the same time, however, he concludes that the prospects for forest farming are limited by a number of important factors. Among these limiting factors are listed: the scarcity of available lands adequately stocked with forest growth, high capital requirements, lack of managerial talent, lack of interest and incentive for forest farming in areas where stumpage is readily available from other private or from public lands, and the relative inefficiency of family-sized operations as compared with large-scale commercial logging.

The importance of these limiting factors leads the author to conclude that "it seems unlikely that full-time forest farming will take a large place in the rural economy of either of the regions studied. Part-time forest employment to supplement other farming ac-

tivities appears more applicable to the needs of the resident population and the prevailing level of social and economic development."

A number of public measures now in effect and designed to foster the advancement of forestry by small owners are briefly discussed in the final section. While the author is appreciative of the results achieved, he argues that "the various public programs have barely scratched the surface" in getting small operators interested in actually practicing forestry. To remedy this situation he argues that the public aid programs could and should be strengthened by offering "complete forest management service" to small and nonresident owners.

Historical Sociology: Its Origin and Development. Theories of Social Evolution from Cave Life to Atomic Bombing. Harry Elmer Barnes. New York, Philosophical Library. Pp. x & 186. \$3.00.

The well known historian of social ideas presents here a new cross-section of the history of social thought. He surveys the kinds of interrelationships, which have existed between sociology and the various concepts of history, such as Parallelism, Diffusionism, Determinism, etc. Moreover, he passes judgment upon many of such systems, rejecting the following two ways of looking at these problems: (1) The "skepticism" of Hobhouse and Ginsberg, who for example deny any interrelationship between economic structure and form of government and who, Barnes says, divide the forms of life of primitives arbitrarily and obtain from their studies what they had assumed at the outset in their preliminary classifications (p. 57); (2) The constructions of Spengler—a revival of romantic organicism (p. 106); Toynbee—an uncritical "Theodicy" (pp. 107f.); and Sorokin with his subjectively constructed categories and his attempt "to measure the immeasurable" (p. 112). In contrast to such persons Barnes finds merit in Howard Becker's work in the history of methodology (p. 3), Briffault's comparative method based on empirical material (p. 90), Max Weber's ideal type method (p. 60), and Boas' combination of parallelism and diffusionism (p. 75).

One might expect in a book which deals with so many theories that many of them would be incorporated incorrectly into the

historical sequence. But actually one can only find two such mistakes: (1) Ranke and his school (p. 12) have actually been of no importance in the development of sociological thinking. Rather this school has recognized only the existence of a history of foreign politics or insofar as they have taken the existence of social phenomena into consideration they were explained as caused by international relations. By so doing this group has actually hindered the development of a sociological thinking in Germany; (2) Bachofen was of far greater importance than appears in this book (p. 86) since he combined German Romantic interest in the original and often irrational feeling of people with parallel development and by that way has been of great influence on such persons as Frederic Engels and Karl Marx. Except for contesting these two points the reviewer must praise the correctness of the historical explanation and of the methods recommended. Especially is Barnes right in insisting that historically structured sociological systems are competent insofar as they are based on empirically collected material, systematized according to "ideal types." Barnes likewise is right in arguing that the latter may be used only if they are considered auxiliary constructions rather than metaphysical entities which some social theorists claim them to be. Actually, as Barnes points out, such "entities" are of purely subjective character.

PAUL HONIGSHEIM

Michigan State College

Report of the FAO Mission for Siam, Food and Agriculture Organization of The United Nations, New York: Columbia University Press, 1948, Pp. 125. \$1.50.

In this report, which was a result of three months intensive study of the economic and technical problems involved in the development of the agriculture and forest resources of Siam, the Mission specialists jointly present their recommendations regarding (1) Agricultural production, (2) Irrigation, (3) Control of rinderpest, (4) Forestry, (5) Economics of agriculture, (6) Agricultural statistics and (7) Agricultural services. To the agricultural economists, the chapter on Economics of Agriculture is particularly interesting. Here the investigators firmly grasp the importance of the rice economy of Siam, properly analyze it in the order of "Production Problems," "Marketing and Distribution of Rice," "Agricultural Credit," "Land Tenure" and "Co-operative Program"; and finally conclude with a "Plan of Agricultural Development."

The recommendations, 128 in number, are too numerous to quote in length. By and large, they are technical in nature. For this reason, however, they seemed to lack a clear-cut general outlook. The Mission recommended many things that would apply equally to almost any country without inquiring adequately into the causes of the present situation. The Mission also tended to avoid issues that involve political and social complications. For instance, it is no secret that the financing of the suggested program of agricultural development counts heavily on the profit from the export of rice under the monopoly of the Siamese government. The Mission, however, tried not to commit itself to the export monopoly as a system. It said that it does not feel qualified to advise upon such a policy.

At any rate, the programs of rice breeding, of fertilizer experiments, of rinderpest control, etc., are undoubtedly desirable; but if the programs had to move onto a social level such as distributing irrigation water or providing low-cost credit for tenant farmers, the reviewer feels that some of the recommendations would need further analysis.

B. K. SHAO

University of Wisconsin

Agricultural Extension Education in Poland, 1918-1939, Boleslaw J. Przedpelski, New York: King's Crown Press, 1948, Pp. x, 139.

The author states in his introduction that one of the pertinent objectives for this brief work is that of acquainting the rural worker with the Polish Educational Agricultural Movement that occurred between the two wars. This he proceeds to do on the descriptive level with great economy. The work is initiated with a brief historical summary of Poland and Polish agriculture, with emphasis on the various partitions and the eventual founding of the modern Polish State. Succeeding chapters are devoted to continued brief treatments of agricultural organizations in Poland; Chambers of Agriculture, units of agricultural self-government which are given central importance in agricultural adult education; the relationships of such Chambers to agricultural colleges and educational training centers for rural workers; general problems related to the development of agricultural extension education; a summary of statistics about Polish extension work; and a final chapter of summary comments with several references to the philosophy of extension work as it exists in the United States.

The core of this work is the descriptive treatment of the organizational structure of Polish Extension education, with the Chamber of Agriculture as the principal functional unit. The author points out the democratic aspects of this self-governing local unit centered in each province, with each province consisting of eight to twenty-seven counties. On the county level extension work was handled by general purpose voluntary agricultural organizations. Problems connected with such an organization included the lack of national and local integration, the weak relationships with agricultural colleges, and the difficulty of training and maintaining properly trained personnel. The principal educational method is described as that of the organization and management of small farms for demonstration and training purposes.

The author agrees with American students in that extension work is a socio-educational process. However, since this treatment is largely given to organizational structure, the reader may look in vain for more portrayal of the dynamic social and economic aspects of the Polish system which influenced people and local institutions. As a result, one tends to be lost in the organizational complex. A case treatment of a typical extension situation, for example, would have been helpful. Yet, since increasing interest is manifested throughout the world relative to extension work with rural people, this work adds, in spite of its brevity, to the knowledge with respect to adult education programs in rural areas.

NEWS NOTES

The American Institute of Cooperation is conducting two workshops at the University of Wisconsin, Madison, just preceding the institute's annual summer sessions, August 22 to 26. The first, from Aug. 8 to 19, is for teachers on a graduate level with Professor E. A. Perregaux of the University of Connecticut as chairman, and Frank Robotka of Iowa State College discussion leader. The second, from Aug. 15 to 19 is for extension workers with Professor W. H. Dankers, of the University of Minnesota, as chairman and Professor L. A. Bevan, Director of Extension at New Hampshire discussion leader.

A Southern Regional Summer School in Agricultural Marketing will be held at North Carolina State College, Raleigh, from June 16 to July 29, 1949. With the assistance of the General Education Board, ten fellowships for graduate students and ten scholarships for undergraduate students have been made available. Professors Marvin A. Schaars of Wisconsin and Geoffrey Shepherd of Iowa will be visiting faculty members. Special lecturers also will be invited to participate.

A number of administrative changes have been made at Michigan State College. Dr. Herman J. Wyngarden, Head of the Department of Economics, will become Dean of the School of Business and Public Service on July 1, 1949. On the same date, the Section of Agricultural Economics is to be transferred to the School of Agriculture to become part of a new department, which is also to include the Department of Farm Management.

The Department of Economics is to be transferred from the School of Science and Arts to the School of Business and Public Service.

The New York Milkshed Price Committee submitted its report on the pricing of Class I-A milk at a meeting at Syracuse, New York, Feb. 21, 1949. Copies of the complete text of the report of the New York Milkshed Price Committee are available upon request from Dr. C. J. Blanford, Market Administrator, New York Metropolitan Milk Marketing Area, 205 East 42nd St., New York City. Members of the committee were appointed by Dr. Blanford from Cornell, University of Connecticut, University of Vermont, New York University, Pennsylvania State College, St. Lawrence University, and Columbia University. They worked on the report from November, 1947 through January, 1949. Dr. F. F. Hill, Professor of Land Economics, Cornell University, was chairman.

A bulletin recently released by the Bureau of Agricultural Economics is the first publication to give a complete statistical series of estimates of bearing fruit acreages by crops and by states. It covers the years 1919-46 and is the result of several years' research in which available data were supplemented with additional surveys to arrive at reliable estimates.

Statisticians in the Bureau of Agricultural Economics have undertaken an investigation of the problems of estimating local-market supplies of vegetables for metropolitan areas. The Bureau's present estimates of commercial vegetable production do not cover all of the local-market segment of this production.

The students in the Departments of Agricultural Economics and of

Agricultural Administration at Mississippi State College have organized a student section of the American Farm Economic Association. The officers are: W. O. Davis, president; I. T. Jones, vice-president; R. E. McCollum, secretary-treasurer; and B. D. Jordon, reporter. Professor John C. Redman of the Department of Agricultural Economics is faculty advisor.

The Division of Field Crop Statistics of the Bureau of Agricultural Economics has begun the basic work of setting up the nation-wide wheat acreage survey which is to be made in June.

Ernest Ahrendes has returned to Montana State College after spending several weeks at Kansas State College for the Bureau of Agricultural Economics in studying the economics of feeding wheat to livestock.

John F. Alexander, working on a rental arrangement study; and John R. Shillinglaw and J. A. Smith assisting with a regional potato marketing project, have been added to the staff of the Department of Agricultural Economics and Rural Sociology as Assistant Agricultural Economists at Clemson Agricultural College. They are February graduates of Clemson.

Clifford Alston, Extension Marketing Specialist, University of Arkansas, is working toward a M.S. degree in business management at Cornell University.

Keith W. Amstutz, who completed his work for a M.S. at Purdue in February, has accepted a position as fieldman in the Illinois Farm Bureau Farm Management Service.

M. E. Andal, Agricultural Economist, Department of Agriculture, Ottawa, was the recipient of an Agricultural Institute of Canada scholarship and for the past year has been on leave of absence at Michigan State College where he has been taking graduate work.

Miss Elna Anderson, an Agricultural Economic Statistician, who had been on the staff of the Bureau of Agricultural Economics in the Division of Statistical and Historical Research for 26 years, died February 13, following a fall in her home in Alexandria, Va.

Mr. Olav V. Anderson, formerly with the Bureau of Agricultural Economics, has been appointed a member of the staff of the Fats and Oils Section, International Commodities Branch, Office of Foreign Agricultural Relations.

William Barr, Associate Professor of Farm Management, Pennsylvania State College, is on leave completing requirements for a doctorate in farm management at Cornell.

W. K. Bing resigned as Associate Professor at Kansas State College to accept a position with the Bureau of Agricultural Economics, Washington, D. C.

William Black has been employed by the North Central Regional Dairy Marketing Committee, and is stationed at the University of Wisconsin, Madison. Professor Geoffrey Shepherd is chairman of the regional committee.

M. C. Bond began sabbatical leave from Cornell University February 1. For two months he traveled through southern U. S. and Mexico and studied marketing for fruits and vegetables. He began work April 1 with the Federal Extension Service in Washington, D.C.

A. J. Boudreau, formerly on the staff of the Economics Department of the Superior School of Agriculture at Ste. Anne de la Pocatiere, Quebec, has been appointed a member of the Federal Civil Service Commission at Ottawa.

Glenn O. Bressler has returned to Pennsylvania State College where he will be a member of the staff of the Poultry Department. He has completed requirements for a Ph D. degree in farm management at Cornell.

Royal Jay Briggs, head of the Department of Social Sciences at Central Missouri State Colleges, Warrensburg, Mo., has completed the requirements for a Ph.D. at the University of Missouri.

Henry M. Brown has transferred to the Washington office of the Bureau of Agricultural Economics from the Agricultural Estimates office at Raleigh, North Carolina. He is working on estimates of cotton and other fiber crops.

Alvin G. Carpenter, Extension Economist, has been transferred to administrative work as Assistant Extension Director at the Utah State Agricultural College, Logan.

L. Wayne Cochran, former Research Assistant at the Giannini Foundation, University of California, has joined the staff of the Citrus Fruit Division, Fruit and Vegetable Branch, Production and Marketing Administration, United States Department of Agriculture.

T. K. Cowden, Vice-President of the American Farm Economic Association, has accepted an appointment as head of the new Department of Agricultural Economics, Michigan State College, effective about May 1, 1949. Dr. Cowden has been Director of Research, American Farm Bureau Federation, for the past six years.

L. C. Cunningham will be in Chicago during his sabbatical leave from Cornell University from February 1 to July 1. He will make an economic study of the commercial feed industry.

Subhas Dahr has completed requirements for a Ph.D. degree in land economics at Cornell University. He will work with FAO in Washington, D. C. for a few months before returning to India.

Herrell DeGraff has taken an eight month sabbatical leave from Cornell University. He is in Mexico studying agricultural conditions for the Rockefeller Foundation.

T. E. Doak has accepted the position of Assistant Dean of the College of Agriculture and Assistant Director of Experiment Station, University of Missouri. Mr. Doak has completed requirements for a doctorate in prices at Cornell University.

Ralph Eastwood, who has been with the Farm Credit Administration, Washington, D. C. has accepted a position with the Cooperative Grange League Federation in Ithaca, New York.

Marven Farrell, who recently completed work for Ph.D. at Harvard, has joined the staff of the Economics Department, Ontario Agricultural College, Guelph.

Rudolf Freund has joined the staff of the Department of Agricultural Economics on a joint basis with the Division of Social Studies, University of North Carolina. Dr. Freund will teach courses in agricultural policies,

land tenure, and agricultural industries. Dr. Freund received his undergraduate and graduate training in Germany and was associated with the University of Virginia prior to accepting a position at N. C. State College.

Dr. Charles D. Hyson and Mr. Ayers Brinser, until recently on the Economic Staff of the Federal Reserve Bank of Boston have joined the Agricultural Marketing Research Staff of Harvard University.

Milton C. Gay retired as economist in charge of the Fruit and Vegetable Section, Cooperative Research and Service Division, Farm Credit Administration on January 22. Mr. Gay was for many years extension marketing economist in Georgia and later the southern representative of a large-scale cooperative marketing fruits and vegetables.

Sidney Gershben has joined the staff of the Bureau of Agricultural Economics, Washington, and is assigned to the Division of Statistical and Historical Research, Fats and Oils Section.

Charles M. Hardin, of the Political Science Department of the University of Chicago, will serve as a special consultant in the Office of the Secretary of Agriculture during April, May, and June, 1949.

Clifford M. Hardin has been appointed Director of the Michigan Agricultural Experiment Station, effective July 1, 1949. He has been assistant director for the past year, and previously had been Chairman of the Section of Agricultural Economics.

V. B. Hart, Cornell University, has been appointed by the Secretary of the Treasury as a member of the National Agricultural Savings Bond Committee.

Cecil B. Haven has accepted a position of Assistant Professor in Agricultural Economics at the North Dakota Agricultural College. He is teaching courses in farm management and production economics and is in charge of research in the same field. He has been granted leave for the spring term of 1949 to complete his Ph.D. thesis at Iowa State College.

Harry C. Hensley retired as principal agricultural economist in the Fruit and Vegetable Section, Cooperative Research and Service Division, Farm Credit Administration, on February 1, 1949. Mr. Hensley for several years served as county agent, district agent, and extension economist in marketing in Missouri.

Louis F. Herrmann has recently returned to the Bureau of Agricultural Economics from five years on the staff of the National Cooperative Milk Producers' Federation. Dr. Herrmann is in charge of research on dairy and poultry marketing in the Division of Marketing and Transportation Research.

F. F. Hill, head of the Department of Agricultural Economics, Cornell University, was in England during January studying the agricultural program of the United Kingdom for the Economic Cooperation Administration.

Asher Hobson, University of Wisconsin, was recently elected Chairman of the Board of Trustees of the American Institute of Cooperation, succeeding Dean W. I. Meyers of Cornell.

M. N. Huda has completed requirements for a Ph.D. degree at Cornell. He plans to obtain training with the Bureau of Agricultural Economics in Washington, D. C. before returning to Pakistan.

Alfred H. Johnson has been appointed Assistant in Research in Agricultural Economics, Rhode Island State College. He is working on Egg Marketing.

Neil W. Johnson, recently Assistant Head of the Division of Farm Management and Costs, Bureau of Agricultural Economics, was appointed Special Assistant to the Administrator of the Agricultural Research Administration in charge of the new Central Project Office of the United States Department of Agriculture.

Paul E. Johnston, University of Illinois, has been granted leave of absence and has joined Overseas Consultants Inc. to aid in a study of economic conditions in Iran. He is in charge of a group of five agricultural men who arrived in Iran February 8 for four months.

J. R. S. Jorgens, who took graduate work at Washington State College, has joined the staff of the Economics Division of the University of Alberta, Canada.

M. S. Kendrick, on leave from Cornell University until September 1, is doing research and writing in taxation.

Walter E. Larmie has been appointed Assistant Extension Instructor in Marketing at Rhode Island State College. He is working on a cooperative project on the marketing of fruits and vegetables.

Marc C. Leager, for twenty years a member of the staff of the Basic Division, died on December 6, 1948. For the past several years Dr. Leager had been a joint member of the Department of Agricultural Economics and the Division of Social Studies, University of North Carolina. His field of interest was farm finance.

Myron W. Madison, Illinois '39, has joined the staff of the University of Illinois as first assistant in agricultural economics. He has been a fieldman in the Farm Bureau Farm Management Service and will help coordinate the work of the fieldmen in his new position.

James G. Maddox has been appointed to the staff of the American Basic Economic Corporation, which is financed by Nelson Rockefeller and Associates, to assist in the development of a habilitation loan program in South America, beginning in Venezuela.

John N. Mahan resigned from the Department of Agricultural Economics, University of North Carolina, to accept a position with the Tennessee Valley Authority. Mr. Mahan was a joint employee with the Bureau of Agricultural Economics on a regional dairy marketing research project.

W. W. McPherson, who has been pursuing graduate work at Harvard University, has joined the staff of the Department of Agricultural Economics of North Carolina State College. Mr. McPherson was formerly an employee of the Bureau of Agricultural Economics. He will divide his efforts between teaching and research in farm management.

W. I. Meyers, Dean of Agriculture, Cornell University, has accepted an appointment to the board of trustees of the Carnegie Institution of Washington, Washington, D. C. Dean Meyers is also chairman of the National Agricultural Savings Bond Committee.

Wm. H. Nicholls of the Department of Economics, Vanderbilt University, delivered on March 21st the first address before the newly organized Social Science Seminar at Mississippi State College.

James Miles, Associate Economist, Marketing Research, Clemson Agricultural College, is working on a doctor's degree in marketing at Cornell University.

E. G. Misner of the Department of Agricultural Economics, Cornell University, is on leave.

Clyde Mitchell has resigned from his position as president of the New Korea Company and is now at Harvard University preparing a report and analysis of the program developed under his administration, which sold back to the farmers of Korea 1,500,000 farms that had earlier been taken over by the Japanese Development Company.

Dr. J. L. Paschal has rejoined the staff of the Bureau of Agricultural Economics, with headquarters at Fort Collins, Colorado. He recently spent 6 months in Alaska and is now engaged in a study of phosphate fertilizers in Western States.

Reed A. Phillips has returned to the Bureau of Agricultural Economics, Washington, after an absence of several months. He heads the research on marketing of livestock in the Division of Marketing and Transportation Research.

Clarence E. Prentice has been appointed assistant professor (Extension) at Michigan State College. He will specialize in grain, bean, and sugar beet marketing. He was formerly county agent in Sanilac County, Michigan.

A. E. Richards, Principal Economist, Economics Division, Dept. of Agriculture, Ottawa, is a member of the Canadian delegation that will be meeting for a period of some months at Annecy, France, in connection with an extension of trade agreements originally drafted at Geneva and Havana in 1947.

Marvin A. Schaars, University of Wisconsin, will be on the staff of the North Carolina School of Agriculture and Forestry, Raleigh, for the summer session teaching two courses in agricultural marketing.

A. Z. Sheira, on leave from the Bureau of Agricultural Economics, Ministry of Agriculture, Cairo, Egypt, completed his M.S. degree in agricultural policy at the University of Illinois, and is continuing his graduate work in Agricultural Economics at Cornell University.

Edward J. Smith, formerly graduate assistant, has accepted a joint appointment with the Wisconsin Agricultural Experiment Station and the Bureau of Agricultural Economics, and will study the farm management problems in making and utilizing grass silage.

Thomas D. Spivey has transferred from the Bureau of Agricultural Economics, Washington, to the Tobacco and Tropical Products Division, International Commodities Branch, Office of Foreign Agricultural Relations, where he will work on statistics of tropical products.

Hugh L. Stewart has been appointed Assistant Head of the Division of Farm Management and Costs, Bureau of Agricultural Economics. This is in addition to his leadership of the Western Agriculture Section of the Division.

Proctor Thompson, Research Associate in Agricultural Economics at the University of Chicago, will join the faculty as Assistant Professor of Economics and Education, beginning in October, 1949.

Ralph D. Tompkin has joined the staff of Iowa State College after completing requirements for a M.S. degree at the University of Illinois.

A. H. Turner, formerly Director of Research, Department of Cooperation, Province of Saskatchewan, has joined the Economics Division, Department of Agriculture in Ottawa, where he will have charge of marketing research.

F. L. Underwood, formerly of Virginia Polytechnic Institute, has joined the staff of the Department of Agricultural Economics at the Oklahoma Agricultural and Mechanical College, Stillwater, and is now doing teaching and research in farm management.

Richard Wheeler, in charge, and W. Herbert Brown and Ernest N. Gould are the research staff working on the project in Dairy Farm Management under a grant from the Charles H. Hood Foundation at Harvard University. The project has recently been expanded to include a study of dairy-woodland combination farming in the farm-forest margin.

Clyde Z. Willis has transferred to the Washington office of the Bureau of Agricultural Economics from the Agricultural Estimates office at Raleigh. He is working on estimates of peanuts.

Martin Young has returned to the Fruit and Vegetable Branch Production and Marketing Administration, USDA, and has been assigned to the Dried Fruit Division. He recently returned from two years in Korea where he was Chief and later Adviser to the Korean Chief of the Bureau of Agriculture in Kyong Sang Namdo Province.

MEETING OF THE EXECUTIVE COMMITTEE
CLEVELAND, OHIO

December 30, 1948

Present: Murray, Wells, Hobson, Waite, Allin, Cowden, Wellman, Norton, and Simerl.

W. G. Murray opened the meeting and presented his report as President for 1948, and it was accepted. L. J. Norton reported that the tellers had reported to him that the following were elected as officers for 1949: President, Oris V. Wells, Bureau of Agricultural Economics; Vice-Presidents, Bushrod Allin, Bureau of Agricultural Economics, and Thomas Cowden, American Farm Bureau Federation; Secretary-Treasurer, L. H. Simerl, University of Illinois.

This was accepted and made a matter of record. Murray suggested that various departments of agricultural economics be notified of the new officers and of the dates of the 1949 annual meeting.

President Wells took the chair. An agenda for the meeting was presented and adopted. The past Secretary-Treasurer presented his annual report and the report of the Investment Committee. These were accepted. He also submitted the auditor's report which was accepted.

The following resolution was adopted:

"RESOLVED, that the Secretary-Treasurer, who is also chairman of the Investment Policy Committee, be and is hereby authorized and empowered for, and in the name and on behalf of this Association to take any and all such steps, and to do any and all such things as may be necessary, required, and appropriate for, or in connection with, the purchase, acquisition, acceptance, handling, pledging, sale, or other disposition of stocks, bonds, and other securities belonging to the Association or pertaining to its business including the execution and delivery for and in the name and on behalf of this Association, or any and all endorsements, transfers, and assignments of certificates of stocks, bonds, or other securities standing in the name of this Association, either for the purpose of sale or transfer, and all such other steps and action as may be necessary or proper in connection therewith."

The Champaign National Bank of Champaign, Illinois was designated as depository of the Association's funds.

The Committee approved a motion to provide for the bonding of the Secretary-Treasurer and his secretary.

The Editor presented his report which was accepted. The following resolution was unanimously adopted: The Committee on behalf of the Association expresses its commendation of the excellent work of Dr. Warren C. Waite as Editor of THE JOURNAL OF FARM ECONOMICS.

Walter W. Wilcox was appointed Editor of THE JOURNAL OF FARM ECONOMICS, for the ensuing year. A sum of seven hundred and fifty dollars was appropriated for technical editorial services (subject to review by the Executive Committee in August). The Editor was authorized to appoint two Assistant Editors.

A budget was adopted as follows:

PRO FORMA BUDGET FOR TWELVE-MONTH PERIOD

Income

Dues.	\$11,030
Back numbers sold... ..	1,000
Reprints sold .. .	300
Dividends and interest .. .	2,000
Advertising .. .	100
Total	<hr/> \$14,430

Expenses

Printing the JOURNAL.	\$ 9,000
Reprints... ..	900
Annual meeting	500
Back numbers... ..	200
Best article award.	100
Editorial expense	750
Executive Committee	300
Library custodian.. ..	25
Office supplies .. .	120
Postage and wires.	200
President's expense	150
Secretary's expense	1,550
Materials for agricultural policy volume	300
Index.. ..	150
Contingent reserve	185
Total	<hr/> \$14,430

A sum of \$1,500 was appropriated to defray a part of the costs of stenographic and clerical services in the office of the Secretary-Treasurer.

The Committee agreed to present to the members of the 1949 annual meeting the proposition of charging a registration fee of \$1.00 at subsequent annual meetings

It was agreed that extra copies of the 1949 Proceedings issue of the JOURNAL would be made available to the Western Farm Economics Association at a reasonable cost to be determined by the Editor and the Secretary-Treasurer of the American Farm Economic Association and the President of the Western Farm Economics Association.

The consensus of opinion of the Executive Committee is that: (1) The program suggested by the Special Awards Committee is too ambitious to be administered efficiently, at least in the first year; (2) the undergraduate essay proposal is impractical of administration; and (3) that the topic of agricultural policy should not be used for at least another year or two.

It was agreed that necessary expenses incident to the meritorious awards be met from the awards fund.

For the first year awards were approved as follows:

I Published report of research	
A. First award	\$ 500
B. Special awards, three at \$100 each.... .	300
II. Doctor's thesis	
First award... ..	250
B. Special awards, two at \$100 each. . . .	200
<hr/>	
Total	\$1,250

Reports of research submitted must bear a publication date of 1946, 1947, or 1948, and be readily available in quantity. Each of the awards in this group shall be in different fields.

Doctor's theses submitted for awards must have been accepted by the student's institution during the three years 1946, 1947, and 1948. Theses shall be submitted through the appropriate department head at each institution and only one thesis shall be accepted from each institution.

No paper shall receive more than one award, but a published Doctor's thesis may be submitted in both classes.

For some time the Association has accepted graduate students as junior members. In order to provide definite constitutional authorization for this practice the Committee agreed to submit the following amendment to the members: "The Executive Committee may establish a junior membership open only to graduate students. The annual dues for such membership shall be \$3.00 per year."

The Committee approved the participation in joint sessions with the American Economic Association in New York in 1949. The President was authorized to proceed with necessary arrangements.

It was recommended that the President appoint a marketing committee to work with the American Marketing Association.

The 1949 annual meeting will be held at the University of Wyoming, at Laramie, August 17 to 20.

The Executive Committee authorized the President to appoint a Membership Committee.

The members of the Executive Committee present unanimously agreed to hold the 1950 annual meeting at Montreat, North Carolina.

L. H. SIMERL, *Secretary-Treasurer*
ORIS V. WELLS, *President*

RURAL HEALTH AND THE TRUMAN PLAN

CALVIN W. STILLMAN*
Chicago, Illinois

A PROPRIETARY interest in "problems" seems to be one facet of our society, organized as we are into so many vocal interest-groups. The pattern seems to be to stamp a problem with one's adjective, and then to repel boarders. For instance in the matter of medical care, Fishbein says:¹

"The medical profession has insisted with remarkable unanimity that no other group except physicians is really entitled to say how medicine should be practiced, for only the physicians are competent by training and experience to judge adequately the quality of medical care. There is no criterion of adequate medical care except the quality of the care that is rendered."

One wonders whether there is not something to be said also for the quantity of medical care, and for the matter of allocation of the various qualities and quantities among all those persons who may be in need of medical care. Another view is Falk's:²

"Social and economic health measures are directed primarily to the effective organization of health facilities and to the adequate provision of health services. They are only secondarily concerned with the technology of medicine. The content of medicine is the physician's domain. But the circumstances under which he practices and his economic relation to society

* The writer wishes to express his appreciation for aid in preparation of this paper from Elin Anderson, Michael Davis, Lynn Doctor, Leonard Engel, Erven Long, and Louis S. Reed.

¹ Morris Fishbein, M.D., "The Doctor and the State," in *The Medical Profession and the Public*, American Academy of Political and Social Science, Philadelphia, Pa., 1934, p. 88.

² I. S. Falk, "An Introduction to National Problems in Medical Care," *Law and Contemporary Problems*, Vol. VI, No. 4, Autumn 1939, p. 500.

or to the individual patient are problems of organization, problems in the public domain in which the physician is only one among many who are vitally interested."

Research into the economic problems of medical care, and proposals for reform from within and without the ranks of the profession, have met the hostility and opposition of the most articulate segments of organized medicine. (The Physicians Forum and the Committee of Physicians for the Improvement of Medical Care, for example, have supported such reforms.) Each new development in public health has been bitterly fought;³ voluntary and philanthropic organizations interested in human welfare have been objects of suspicion⁴ and attack.⁵ Yet despite this apparently automatic reaction to novelty, the medical profession adjusts to each new development as a glacier slides down a valley; it maintains its frigid dignity, but it does move. The contemporary excitement over "socialized medicine" must be viewed in the light of the profession's record of opposition to all that is new.⁶ The day may even be in sight when the medical profession will welcome assistance from other disciplines in studying the problems of the distribution of medical care. Without waiting for this day to arrive, this paper is undertaken in an attempt to point out certain areas in which economics can contribute to a solution of the "medical" problem.

Definition of the Problem

It seems anomalous that we should have such a problem in the United States, yet as evidence that we do there are four major bills before Congress, and a message from the President.⁷ Advances in

³ Gaylord Anderson, "The Political Impact of Modern Science on Public Health," *Annals of the American Academy of Political and Social Science*, Vol. CCXLIX, January 1947.

⁴ Bernhard J. Stern, "Society and Medical Progress," Princeton University Press, Princeton, New Jersey, 1941.

⁵ J. G. Crownhart, "Sickness Insurance and the Propagandist Foundations," State Medical Society of Wisconsin, pamphlet, January 2, 1935. "Sickness insurance" is used to describe any insurance plan not in accord with the policies of organized medicine. "Health insurance" is used to describe approved plans.

⁶ The dean of the medical school of a Midwestern state university has defined "socialized medicine" in a conversation with the writer as "anything the AMA doesn't like."

⁷ The Administration's bill (S.1679) introduced by Senator Thomas and others, and the less controversial bills offered by Senators Taft (S.1581) and Hill (S.1456), and by Representative Javits and others (S.1790). The President delivered his message on April 23, 1949.

knowledge concerning disease have been notable in this century; the life expectancy of our population has soared; by many measures the nation has grown steadily healthier. Yet there exists a problem. What is it?

The problem is to find an institutional mechanism to bring together people and the medical care that is potentially theirs. Our great medical resources are not now giving their services at full capacity. Personnel and institutions specialized for medical care are not distributed in accordance with the needs of the population, nor are they organized to serve most efficiently the people within reach. Need for medical care exists wherever there are people. In our economy, means for providing medical care have grown up in relation to incomes, not to people and their needs for care. Most medical facilities concentrate in urban areas; these areas offer the highest purchase price for medical services. Rural people simply do not know what they are missing in modern medical care.

Statistics collected by the United States Public Health Service indicate that in rural areas rates of mortality are high, and rates of morbidity are high—for diseases classed as “preventable.” Most tragic is the fact that rural rates for maternal and infant mortality are particularly high.⁸ Mott and Roemer say in a summary paragraph of their invaluable volume on rural health,⁹

“People in cities have long looked on rural life as the healthful life, and 40 years ago in this country they were close to the truth. Rural people were then healthier as a group, the toll of fatal disease and premature death was much lower among them. But movements were already afoot and trends taking shape that were to mean progressive and rapid improvement in urban health, a dramatic advance only feebly reflected and far from paralleled by the lagging betterment of rural health during the same decades.”

The very nature of the organization of rural life makes difficult the necessary contacts between physician and patient. In 1940 only one fourth of all farms had telephones, and forty-two percent of all farm operators were without automobiles of any kind.¹⁰ It is the custom in many rural areas for the physician to charge one dollar

⁸ Statistics and special studies are published regularly in the Public Health Service's periodical, *Public Health Reports*. For summarized data on rural health statistics, see Frederick D. Mott, M.D., and Milton I. Roemer, M.D., “Rural Health and Medical Care,” McGraw-Hill, New York, 1948, chapters 4 through 7.

⁹ *Ibid.*, p. 49.

¹⁰ *Ibid.*, p. 35.

per mile for a home visit, in addition to his regular fee.¹¹ Distribution of medical services to rural people is more expensive, and their means of payment are less, than in urban areas. Rural people thus have an interest in the solution of the national problem of the distribution of medical care; few groups have more to gain.

Progress in medical knowledge from the horse-and-buggy stage has introduced three general problems which must be solved by a new institutional mechanism; by a new method of organization, in Falk's terminology. The problems as the economist sees them are those of complexity, cost, and concentration. These will be discussed in turn.

The Problem of Complexity

The vast and increasing scope of medical knowledge, compared with a generation ago, has been illustrated by Dr. Benjamin Miller through the example of training for general practice. For a doctor of today to become trained in all the fields of medicine offered by the traditional general practitioner would require an aggregate of internships lasting seventeen years. At the end of that time, says Dr. Miller, the earlier fields studied would have been so changed that it would be necessary to repeat them. The conscientious trainee for general practice would consequently never leave school.¹²

Not only is specialized training necessary for modern medicine; student doctors are taught to work with specialized aids of sorts rarely found far from hospitals. Modern medical care practically requires the existence of hospitals. Modern doctors learn to rely upon the trained assistance of nurses and technicians, and to use the highly-developed diagnostic aids available in X-ray, pathological, and bacteriological laboratories. The hospital itself provides an efficient center of operations for the physician dealing with the problems of his patient; everything he will need in a wide range of cases is at hand; other physicians consulted fit smoothly into the routine. In every case it is not necessary to call upon the services of several diagnostic aids, or to prescribe several complicated treatments, but

¹¹ For instance, "I live in a county that doesn't have an active practicing physician. The nearest physician is 22 miles away. The flat charge is a dollar a mile. The low income group in American agriculture simply doesn't get medical service from that kind of charge. They go without it . . ." Ransom E. Aldrich, "The Farmer's Medical Care Problem," *Journal of the American Medical Association*, Vol. CXXXI, No. 6, June 8, 1946, p. 553.

¹² Benjamin F. Miller, M.D., *You and Your Doctor*, Whittlesey House, New York, 1948, years required for interning in the various specialties are tabulated on page 17.

the fully-equipped hospital is a guarantee that when the need arises, the service is at hand. The advances in medicine which make possible cures in cases formerly hopeless require persons of many skills and these persons need the tools of their trades.

Good medical service for rural areas requires the existence of all health services, in proper supply. To the extent that the services are specialized—almost a synonym for modern—there must be a method of coordinating them. The supply of no health service is up to par in rural areas. Hospitals and diagnostic laboratories are in very short supply.¹³ The supply of physicians is far below par; the supply of specialists even further below.¹⁴ Although there are exceptions, and most rural physicians are hardworking and conscientious members of their communities, "the environment of country practice is one of continuous frustration and continuous inability to do the things that the thoughtful physician realizes are indicated . . . he rarely can find the opportunity to go away for a state medical society meeting, a refresher course, or postgraduate studies, and, after a while, he loses interest in the idea. As the years go by, he tends to become more firmly lodged in an intellectual rut, and soon the detail men from the various drug houses become his chief source of information on current therapeutics. . . . Even local medical societies, which might tend to provide a certain amount of ethical and professional guidance to practitioners, are as a rule much weaker in every way in rural counties than in the cities."¹⁵

The proliferation of new services in the medical world—each justified by its role in new methods of healing—has been accomplished within the framework of the fee-for-service system of medical billing. It is a canon of organized medicine that the physician's special skill at diagnosis and treatment extends to the field of charging for his service. To practice medicine has been interpreted as to be free to charge what one thinks best. When the services of several physicians are needed, therefore, there are as many separate bills, each an amount set by the physician concerned. Also, there are separate bills for hospitalization, and usually for each service offered by the hospital beyond room and routine food and nursing.

For the patient, enjoyment of the wonders of modern medicine requires a balancing of the possible merits of each suggested treatment with the probable cost. For the physicians concerned, each

¹³ Mott and Roemer, *op. cit.*, chapters 13, 14, 15.

¹⁴ *Ibid.*, chapter 8.

¹⁵ Mott and Roemer, *op. cit.*, p. 183.

can charge as a discriminating monopolist. Only the hospital and the services sold under its auspices are on a flat rate. For the patient, there may be the additional problem that the services needed are physically scattered. Thus a patient with an illness which might involve care of more than a routine sort faces a maze of special charges, some of them not to be determined until after the treatment has been given. His personal physician, who is responsible for guiding his choice and for suggesting the proper expenditures in the search for health, knows that his guidance must be tempered with an understanding of the patient's pocketbook. This obtains in the interest of the physician's own fee, if not in the interests of the patient.

Ability to pay for medical care has become a factor in medical judgment. The traditional "scaling down" of fees to persons of low income has become lost in the new world of institutionalized medicine. The individual's personal physician can scale his own fees up or down, but the hospital demands payment, and the specialist or the physician operating the diagnostic laboratory need have no charitable feelings toward a patient hitherto unknown to him. There are usually plenty of patients who can pay; if there are not, the physician can move to a place where his services are better rewarded.

There are two ways to take the dollar sign out of medical judgment. One is to provide all services at no charge. The other is to make a single charge for an entire treatment, whatever it entails. This charge may vary in proportion with the treatment given, but a single charge can be scaled to a patient's ability to pay; even if there is monopolistic billing, there is at least only one monopolistic proboscis in the pocketbook.

The device of charging once for a complete treatment has been developed by teams of physicians, usually with their own technicians and sometimes with a hospital as well, organized into "medical group practice." The underlying idea of group practice is that the patient is a single unit needing coordinated treatment, and the group attempts to pool its knowledge and skill in providing the treatment necessary. Physician members of a group are ordinarily representatives of complementary specialties. The patient can be examined by any or all of the physicians without leaving the office. The matter of payment is only loosely related to treatment. In many groups, payment is wholly divorced from treatment; these

groups use prepayment plans, or are organized specifically for patients by their industrial or labor organizations, with doctors on salaries.

Rural communities have experimented successfully with medical group practice, frequently in conjunction with prepayment plans. Perhaps the best known of these is the plan at Elk City, Oklahoma, sponsored by the Farmers' Union.¹⁶ Other plans, with or without prepayment plans, have been started in Nebraska, Texas, North Dakota, and other states.¹⁷

Varying types of experiments in reducing the barriers to rural health due to complexity and disorganization are those of the Bingham Associates Fund,¹⁸ aimed at bringing modern diagnostic techniques to rural Maine, and of the Commonwealth Fund,¹⁹ dealing with the coordination of the services of hospitals in the neighborhood of Rochester, New York.

Medical societies have been bitterly hostile to the principle of group practice, whether organized under the auspices of their own members or upon the initiative of laymen. The American Medical Association got its fingers burned for abetting the Washington, D.C., Medical Society in the latter's struggle to kill off an early plan, Group Health Association, Inc.²⁰ The Supreme Court's decision was handed down in January, 1943. Ever since then, the battle has been carried on at the state and county medical-society levels; fired by latent dislike rather than clear editorial directives from the medical press. The number of medical groups in the nation still is not large, partly as a result of this local opposition. The device is extremely interesting, however, and has received attention from

¹⁶ For a spirited account of the early history of this plan, see Michael A. Shadd, *A Doctor for the People*, Vanguard Press, New York, 1939.

¹⁷ See, for instance, Elin L. Anderson, "Adequate Medical Care for Rural Families," *Journal of Home Economics*, XXXVI, No. 7, September 1944, and the publications of the Cooperative Health Federation of America, 343 South Dearborn St., Chicago, Ill.

¹⁸ "The Bingham Associates Fund," pamphlet published by the Fund, 80 Bennet Street, Boston, Massachusetts, April 1945. ²⁰ The Department of Justice successfully brought action against AMA, the District of Columbia Medical Society, and other defendants under the Sherman Act. Most interesting is the evidence secured by the Government by subpoena of the records of the AMA's Bureau of Medical Economics. This evidence is published in the Record on Appeal with the proceedings of the Circuit Court. The judicial history is to be found in 26 Fed Supp 429, 110 Fed 2nd 703, and 317 U.S. 519.

many physicians seriously interested in improving the organization of medical care.²¹

The Problem of Cost

Cost of medical care has an economic significance distinct from its role within the problem of complexity and the effect of discrete unit costs upon medical judgment and treatment prescribed. Medical needs are unpredictable, and peculiarly subject to inelasticities of demand on the part of the afflicted person. Few budgets can handle the charges for a serious illness. Treatment for conditions requiring expensive care over long periods has been recognized as too great a charge upon individuals, and public assumption of these charges has long been the rule. It surprises some persons to learn that three-fourths of all hospital beds in the nation are in government hospitals; that about half of all beds in the country are occupied by mental patients. Mental disease, tuberculosis, and certain chronic and degenerative diseases have been "socialized" for many years in this country.²²

For all the magnitude of the charges for a serious illness, the incidence is so low that the average family does not appear to have a problem. For many years the total cost of medical care, measured as a share of consumer budgets or as a share of the national income, has hovered around four percent. This fact is used by the American Medical Association in arguing that there is no problem of cost in medical care.²³ Invidious comparisons are drawn with the larger

²¹ See "An Annotated Bibliography of Group Practice," pamphlet, American Medical Association, 1948, and G. Halsey Hunt, M.D., and Marcus Goldstein as listed in this bibliography, and succeeding articles in their study of group practice under the auspices of the Public Health Service.

The enthusiastic distrust of organized medicine for innovations suggested from without reached a point during the 80th Congress where government employees were actually fearful of discussing health problems with farm groups. See in this connection "Investigation of the Participation of Federal Officials in the Formation and Operation of Health Workshops," Third Intermediate Report of the Committee on Expenditures in the Executive Departments, 80th Congress, 1st Session. House Report No. 786, July 2, 1947; Hon. Forest A. Harness, "Forcing Socialized Medicine on America by the Use of Federal Employees and Government Money," *Arizona Medicine*, vol. V, No. 1, January 1948; "Rural Health Problems Considered and Policies Adopted at Meetings of Grange and Farm Bureau in Columbus," *Ohio State Medical Journal*, vol. XLIV, No. 1, January 1948.

For a general treatment of the manner in which opinion is formed and controlled within the medical profession, see Oliver Garceau, "The Political Life of the American Medical Association," Harvard University Press, Cambridge, Mass., 1941.

²² An authoritative source for all hospital statistics is the annual "Hospital Number" of the *Journal of the American Medical Association*, published every Spring.

²³ Frank G. Dickinson, "Is Medical Care Expensive?" American Medical Association, Chicago, pamphlet, 1947.

fractions of the national income accounted for by non-essential items. But the importance of a medical cost is not in its average size. It is in the impact of the cost upon the family or individual which must handle this among its other economic adjustments. If there is a magnitude to be measured in medical costs, it is the magnitude of their variation, not their average size.²⁴

Medical care insurance is the obvious mechanism to eliminate the magnitude of variation in cost of medical care. This has been recognized grudgingly by organized medicine only within the last five years. The history of health insurance in this country in the last fifteen years is a story of steady back-tracking by the medical profession. The Committee on Costs of Medical Care reported in 1932 that group practice and voluntary health insurance would help in a solution of the problem of distributing medical care. The editorial reaction of the medical profession was intemperate in the extreme.²⁵

Prepaid hospitalization insurance with benefits on a service basis sprang up in the early 1930's, despite opposition of organized medicine. The plans prospered, and banded together under the trademark "Blue Cross." Medical approval in principle followed after the success of the plans was assured. Special legislation was sought by hospital administrators to excuse their prepayment plans from the rules for insurance companies.²⁶ Starting about a decade ago, insurgent state medical societies ventured into forbidden territory and began instituting prepaid medical care plans of their own devising. The leaders in this movement were the medical societies of California, Pennsylvania, Massachusetts, Michigan, and New Jersey.

²⁴ A classic statement of this concept is to be found in I. S. Falk, Margaret C. Klem, and Nathan Sinai, "The Incidence of Illness and the Receipt and Costs of Medical Care among Representative Families," (Publication of the Committee on the Costs of Medical Care, No. 26, University of Chicago Press, Chicago, 1933, pp. 234-235.) Phraseology of this sentence is borrowed from that report.

²⁵ See editorials in the *Journal of the American Medical Association*, Vol. IC, No. 23, December 3, 1932, and Vol. IC, No. 24, December 10, 1932. Years later an explanation was made for the extreme position of those days, at least implicitly, in Morris Fishbein, M.D., "The Public Relations of Modern Medicine," *Journal of the American Medical Association*, Vol. CXXX, No. 8, February 28, 1946. The report proper is "Medical Care for the American People; the Final Report of the Committee on the Costs of Medical Care." University of Chicago Press, Chicago, 1932.

²⁶ C. Rufus Rorem, "Enabling Legislation for Non-profit Hospital Service Plans," *Law and Contemporary Problems*, Vol. VI, No. 4, Autumn 1939. The early laws specified certain representation on boards of directors; for instance that one third of the board be practicing physicians, and one third hospital administrators. This is important in that there is recognition that a hospital should be dominated by no single professional group if it is to give its best service. For an excellent presentation of the philosophy of the hospital, see Henry J. Southmayd, "Small Community Hospitals," The Commonwealth Fund, New York, 1944.

Special legislation was sought to help these plans also, but with an important difference—legislation was urged by medical societies in forms which would guarantee complete medical control of every aspect of the prepayment process.²⁷ This had the effect of killing plans proposed by lay groups, particularly those to be organized as cooperatives or as adjuncts of group practices

In 1945 the American Medical Association capitulated to prepayment plans organized by medical societies, and began sponsoring the device as a means of combating the rising threat of national health insurance. At its June, 1949, meeting, the Association changed fronts in the matter of consumer-sponsored medical prepayment plans, by announcing that these may be tolerated if they meet certain specified conditions. Since the most effective weapons at the disposal of medical societies are in the hands of the county societies, this revised attitude does not guarantee that any actual change will take place.²⁸

The principle of health insurance has been so well accepted by now that its extension is central to the four major bills before the Congress. The Taft and Hill bills propose governmental aids to the extension of health insurance plans organized in accordance with the views of the medical societies; the Javits bill proposes governmental aid to consumer-controlled cooperative voluntary health plans; the Administration bill proposes nation-wide compulsory health insurance financed by payroll deductions. The Javits and the Administration bills provide for contributions in proportion to

²⁷ See Richard R. Cranmer, M.D., "Medical Care Incorporated," *Bulletin of the Hennepin County Medical Society*, Vol. XIX, No. 1, January 1948, for the story of the drafting of the desired legislation in Minnesota, also William J. Burns, "The Michigan Enabling Act for Non-profit Medical Care Plans," *Law and Contemporary Problems*, Vol. VI, No. 4, Autumn 1939, and Hartley F. Peart and Howard Hassard, "The Organization of California Physicians' Service," *Ibid.* For a recent summary of the monopolistic aspects of this type of restrictive legislation, see "Restrictions on Free Enterprise in Medicine," pamphlet, Committee on Research in Medical Economics, 1790 Broadway, New York; and Margaret Klem, "Recent State Legislation Concerning Prepayment Medical Care," *Social Security Bulletin*, Vol. X, No. 1, January 1947. The best overall study of voluntary plans organized by hospitals and by medical societies is Louis S. Reed, "Blue Cross and Medical Service Plans," U S Public Health Service, Washington, October 1947, processed.

²⁸ See William L. Laurence, "AMA Lists Health Plan Tests with Local Units as Judges," *New York Times*, Friday, June 10, 1949. The weapons at the disposal of county medical societies are expulsion of offending physicians, and actions leading to exclusion from practice in local hospitals. See J. W. Holloway, Jr., "Hospitals and the Selection of Medical Staffs," *Wisconsin Medical Journal*, Vol. XLII, No. 11, November 1948. Also see the record of the AMA's trial in the Group Health case, *op. cit.*

income, the Taft and Hill bills do not. It is alleged that after a few more years, the voluntary plans will attain the coverage visualized for the compulsory plan. Certainly recent growth of voluntary plans has been amazingly rapid, but there is reason to believe that this is to be accounted for by the late appearance of many of the plans, and by the even later endorsement and promotion of them by the medical profession. A survey of the present coverage of voluntary health insurance shows that Blue Cross hospitalization plans cover about 33 million persons in the United States, of whom 60 percent live in six industrial states. These plans will cover about one-fifth of a family's total medical costs.

Medical society prepayment plans ("Blue Shield") cover about ten million persons, practically all of whom also have Blue Cross coverage. Over 85 percent of these persons are in seven high-income states. These plans do not cover all medical needs. Most frequently, they cover only surgical or obstetrical charges, when the patient is in a hospital. Some plans also pay for such items as care given in the doctor's office. All physicians' services in a hospital amount to about fourteen percent of the total medical bill of an average family. Blue Cross and Medical Society plans together, then, will cover about 35 percent of the charge for a serious illness.

Comprehensive service plans, such as that at Elk City and others organized by consumers through cooperatives, unions, industrial health plans, etc., cover between three and three and one-half million persons in many plans scattered over the country. Such plans cover nearly all medical costs.

Commercial insurance policies have been sold to about twenty million people. These policies are characterized by a low ratio of benefits to premiums paid, and like most Blue Cross and increasing numbers of Medical Society plans, benefits are paid in the form of cash payments, unrelated to the actual size of the bill received. The usefulness of these policies is further limited by the fact that many people with some form of unfavorable medical history, and therefore usually in most urgent need of coverage, are either not eligible for health insurance or else have riders attached to their policies precluding payment for any recurrence of a pre-existing ailment. These are often the persons most ruinously crippled financially by persisting ill health.

These figures conceal an unknown amount of duplication, since many persons hold commercial policies as well as Blue Cross mem-

bership or membership in other health plans.²⁹ Of all these millions, how many are rural people? Secretary Anderson said in January, 1948, "Prepayment plans for surgical and other medical services offered by State and county medical societies have today reached less than one percent of the country people."³⁰

Requirement of group membership is usual for Blue Cross and Medical Society health plans; groups ordinarily are comprised of the employees of a factory, an office, or another institution capable of subtracting dues from a payroll. A voluntary health plan requires for safety a reasonably heterogeneous clientele, and one large enough to spread the risk. Every such plan has barriers to membership aimed at decreasing the claim ratio for the plan as a whole. It is safer to enroll people in groups classed on some basis such as a common place of employment, than to allow individuals to select themselves as clients on the basis of their probable future needs for medical care. This means that the health of the plan in a financial sense may militate against the health of just the individuals who most need medical care. These people are not allowed to join, for they would take more in benefits than they would bring in premiums. By the same token, longtime members of a voluntary plan may be dropped summarily for reaching a certain age, or for incurring a condition which is liable to be a precursor of more charges. Rural populations, needless to say, are not easily handled through group enrollments, nor can their premiums ordinarily be paid through payroll deductions.³¹

The existence of a prepayment plan is one thing; the policies of its controlling body is another. There is room for administrative judgment within the limits of financial solvency. Shall the plan be attuned to the special needs of the consumers, or to the special interests of the individuals who provide the services? Medical Soci-

²⁹ This information is taken from a report prepared by Katherine G. Clark for the Committee on Research in Medical Economics, 1790 Broadway, New York City, March 1949.

³⁰ Margaret C. Klem and Margaret F. McKiever, "Program Developments and Benefit Trends in Voluntary Health Insurance," *Social Security Bulletin*, November 1948, p. 4.

³¹ A personal letter by the writer to the headquarters of Associated Medical Care Plans, Inc., the trade association of the Medical Society prepayment plans, elicited the information that nothing is being done at present to increase rural enrollments, but that Blue Cross plans in thirty-seven states have made provision for enrolling groups of farm people, and that in twenty-seven states, it is possible to join Blue Cross without being a member of an organized group.

ety plans have been attacked severely for ignoring the needs of the consumer and for catering to the interests of physicians.³²

When service to the consumer is the guiding motive, a prepayment plan can contribute to a marked increase in the amount of medical care even a relatively isolated community can obtain. A good example is the combined group practice and prepayment plan of the Trinity Hospital, Little Rock, Arkansas. This plan serves persons from all parts of the community with very few membership restrictions, and handles the added liabilities of aged clients through modest increases in their premiums. Margaret Klem has estimated that,

"The volume of services received by Trinity subscribers and their dependents was comparable with that purchased by persons with annual incomes of \$10,000 or more who paid about four times as much for the services received on a fee-for-service basis."³³

It should be emphasized that this prepayment plan is on a service-indemnity basis, not cash-indemnity. To what extent the difference in cost of the medical care received is attributable to better coordination of services, and to what extent to elimination of separate discriminatory monopolistic charges, would make an interesting study. Were cash-indemnity the rule instead of service, monopolistic charging would remain.

The Farm Security Administration conducted experiments with prepaid medical care for its clients for a number of years. The plans set up were financial failures, but subscribers benefited and their physicians benefited. The first year's report of one plan shows a rate of 1,409 medical treatments per thousand members, which is to be compared with a rate of 526 treatments per thousand members of the general rural population.³⁴

The medical profession sanctioned these plans as long as they were approved by the local medical society. Approval was usually forthcoming; the federal subsidies that were necessary to keep the plans afloat meant fewer unpaid medical bills. For instance,

"One physician in Ohio told of 36 families, now members of the unit, who, prior to the establishment of the FSA plan, had received service from him.

³² See Michael M. Davis, "Health Insurance Plans under Medical Societies," *Medical Care*; I Vol III, No. 3, August 1943; II, Vol IV, No. 1, February 1944.

³³ Margaret C. Klem, "Medical Services Provided under Prepayment Arrangements at Trinity Hospital, Little Rock, Arkansas, 1941," *Social Security Bulletin*, May 1947, p. 8

³⁴ Mott and Roemer, *op cit*, p. 418.

Of total charges of \$900 only \$150 could be collected. If these families had had a group plan at that time, he would have received about \$700 at the present rate of payment."³⁵

The FSA prepayment plans were doomed to financial failure because they were limited to persons with high medical needs and low incomes. The purchasing power of any prepayment plan is limited by the size of its clientele, the rate of illness, and the levels of premiums the subscribers can pay. Needless to say FSA clients could not afford much even in monthly instalments; not nearly enough to buy themselves complete health care. Added to this, membership was voluntary, and membership became highly correlated with incipient need for treatment. Prepayment can pool a group's risk, but it cannot raise the level of the pool.³⁶

The Problem of Concentration

"Under any system, if a doctor is a good one, he's bound to go where he can make a good living. Under the present system of individual fees-for-service, doctors go where folks have dough."³⁷

This quotation gives an important reason for the concentration of doctors—and other health facilities—in areas of high per capita income. The quotation suggests that equalizing effective demand for medical care would automatically bring about a distribution of health services more in accordance with physiological need. This is too much to expect, however. In the long run, equalized medical purchasing power would lead to a far more equal distribution of medical facilities than we have at present, but there would still exist differences in locating factors for physicians and other mobile medical services.

The very existence of crowded cities is an attractive force for medical centers. More people close together mean more chances to treat rare and interesting diseases; highly specialized personnel will still prefer to locate near persons and equipment highly specialized and complementary. The dispersed nature of rural populations means that medical facilities to serve them can never be the same as those best fitted for urban areas. Properly planned to meet local

³⁵ Franz Goldmann, M.D., "Medical Care for Farmers," *Medical Care*, Vol. III, No. 1, February 1943, p. 29.

³⁶ An interesting study is that of Robert L. McNamara and A. R. Mangus, "Prepayment Medical Care Plans for Low-income Farmers in Ohio," *Agricultural Experiment Station Bulletin* 658, Wooster, October 1944.

³⁷ Paul de Kruif, *Kaiser Wakes the Doctors*, Harcourt, Brace, New York, 1948, pp. 78-79.

conditions, however, rural health services can provide most of the necessary treatments, and unusual cases can be sent to urban centers.³⁸

Equalizing purchasing power is a prerequisite for equalized medical service, but it is not sufficient, for hospitals do not grow like mushrooms. In the short run, medical facilities required in medically impoverished areas can be supplied through no other means than public funds. This is the objective of the Hospital Survey and Construction Act of 1946, which calls for a survey of the hospital needs of every state, and for grants in aid for construction of hospitals in areas not adequately served. A section of the law requires that the community needing a hospital be wealthy enough to support it, once built. The effectiveness of this law naturally depends upon a device for equalizing medical purchasing power; many communities needing hospitals cannot now afford their support.³⁹

The dimensions of the differences between farm and urban income are greater than one might suppose.

"Passing over the strikingly low prewar farm income figures revealed by the 1939 Census of Agriculture and coming up to the period when the war was having a marked influence on farm incomes, we may recall that in 1941 half of all farm operators had annual net cash incomes of less than \$760 per family, including income from all non-agricultural sources. As the war went on, farm income soared to unprecedented heights, but the disparity between farm and city income levels was still far from eliminated. In 1943, when farm income was approaching its peak, the total net income from all sources of persons on farms was only 12 percent of the national income, although farm people made up 20.5 percent of the population that year. The serious disadvantage of the families looking to the soil for their main livelihood, moreover, is seen in the remarkable fact that the per capita net income in 1943 of all persons in the United States not living on farms was twice as high as persons on farms."⁴⁰

Differences in medical buying power are regional differences, rural-urban differences, farm *versus* non-farm differences; they are differences that allow large communities to enjoy one level of adequacy of medical care, and pen up other large communities at lower levels. No private voluntary insurance plan can equalize

³⁸ For a plan of rural health centers and hospitals, organized in a state-wide network with supporting city hospitals and medical centers, see "Hospital Resources and Needs," *Report of the Michigan Hospital Survey*, W. K. Kellogg Foundation, Battle Creek, Mich., 1946.

³⁹ Written statement submitted by the U. S. Public Health Service, Hearings on S.614, May 4, 1949.

⁴⁰ Mott and Roemer, *op. cit.*, p. 479.

these levels. Localized plans—even one with an entire state for its scope—can do no more than equalize risk within the area covered. No such plan can raise the buying-power for the group as a whole. This is a compelling argument for a national system of equalizing medical buying power, a system inclusive of all areas and all communities, all risks pooled in one fund, and the purchasing power of the fund made available for the benefit of everyone. This is the type of solution envisaged by the Administration in its proposal for compulsory national health insurance.

Compulsory health insurance would be administered as part of the nation's social security framework. Payroll deductions in proportion to income would comprise the cost to the individual. Benefits would come in the form of comprehensive services; practitioners and hospitals would be recompensed by the appropriate administering agency. For employed persons, costs would be close to the average now paid by all families for medical care. This means elimination of uncertainty at no added average cost. Complete coverage, healthy persons along with sickly, guarantees a favorable risk ratio.

According to an official source, "Contributions equivalent to about three percent of annual earnings would pay for adequate basic medical and hospital services for both workers and their dependents. A more comprehensive system would cost the equivalent of about four percent. These costs would be no more than now is spent by families on the average. They are less than the average expenditure by families in the low income groups, since, contrary to the general impression, low-income families spend, on the average, a larger proportion of their incomes for medical care than families in better circumstances, though—because of their more frequent and severe illness—they receive much less in relation to what they need."⁴¹

For everyone, compulsory health insurance should plow down the hills of unpredictable cost and fill the open spaces with a regular premium keyed to income. The same levelling would apply to medical purchasing power interpersonally; the city man with a dependable salary would have as much ability to pay a doctor as a man trying to dry-farm in New Mexico. This alone would not bring the same care to each man, of course, but one barrier would be removed.

⁴¹ I. S. Falk and Wilbur J. Cohen, "Social Security for Farm People," this *Journal*, Vol. XXVIII, No. 1, February 1946, pp. 93-94.

Farmers stand to gain from this type of inter-regional levelling of purchasing power. Whereas the national average expenditure for medical care is about four percent of the family's income, a study indicates that in 1941 medical care was taking 8.7 percent of the average farm family's net cash income.⁴²

The Social Security Administration estimates that there is now an excess capacity in doctors' services of about 25 percent. An immediate effect of compulsory national health insurance can be expected to be an increase in health services supplied by some such amount.⁴³ In the longer run more doctors and hospitals would be needed, and these much better distributed. With national compulsory insurance, there would be the purchasing power to hold in place medical service facilities properly planned to serve the people who need them.

The Administration's Bill

Bills for compulsory health insurance of the same general nature have been introduced by Democratic members of Congress since 1938.⁴⁴ Since 1945, with passage looming as a possibility, the medical profession has become increasingly active in opposition to these bills. The profession's arguments have not been dignified by presentation of facts and their logical discussion. Rather the medical contentions have been couched in emotionally-charged adjectives, and in allegations of insidious motives. For all the furor, there is nothing really new about the Administration's present bill, except that it might pass.

In view of the foregoing analysis of the medical problem in the United States, it is of interest to dissect the Administration's current national health bill title by title.

Title I declares the existence of a shortage in medically-trained personnel, and provides for grants to states for medical scholarships, and to medical schools. The existence of a shortage is largely predicated upon the increase in effective demand which would follow enactment of national compulsory health insurance.

Title II provides for an acceleration of research into certain prob-

⁴² Mott and Roemer, *op. cit.*, p. 308.

⁴³ George Soule, "The Costs of Health Insurance," pamphlet published under the auspices of the Committee on Research in Medical Economics, Inc., New York City, and the Public Affairs Institute, Washington, D. C., April 1949.

⁴⁴ Harold Maslow, "The Background of the Wagner National Health Bill," *Law and Contemporary Problems*, Vol. VI, No. 4, Autumn 1939, provides a running start on the legislative history of compulsory health insurance

lems of poliomyelitis, diabetes, arthritis, epilepsy, and other diseases.

Title III amends, extends, and increases authorized appropriations under the Hospital Survey and Construction Act for hospital construction in underprivileged areas.

Title IV provides special aids for rural and other shortage areas. These are,

Grants and loans to trained personnel to encourage their moving to underprivileged areas.

Grants to aid construction or operation of group practice facilities, clinics, hospitals, etc., including ambulances and mobile clinics

Grants to enable professional personnel in shortage areas to return to medical centers for refresher training.

Grants and other aid to farmers' experimental health cooperatives.

Title V provides for grants to states for public health work.

Title VI provides for research and grants to the states for maternal and child health services.

Title VII provides for compulsory health insurance, but without taxing clauses. These are reserved for a separate bill. Fiscal arrangements are to be handled through a "Personal Health Services Account" on the books of the Treasury, into which would be paid all contributions from covered persons, and what appropriations become necessary. Administration is provided through state channels, and subordinate "health-service areas."

Nothing comparable in scope to the Administration's health plan has been proposed by any other bill before Congress. The novelty and potential difficulties of the plan proposed must be measured not by past methods of organizing medical care, but by the medical needs as yet unmet. To contradict Dr. Fishbein, we *must* think also of the quantity of medical care provided in our society. The cooperation of physicians is essential to any plan of medical care, of course, and there is no reason to believe that such cooperation would not be forthcoming in the proposed national insurance system. For doctors don't gain when they lose patients with several perfectly good years of life left in them. It would be better all around, perhaps, if the medical profession were more prone to cooperate in the solution of this "medical" problem, and less prone to preserve the past by ignoring the present.

THEORY: DEFINITION AND PURPOSE

BUSHROD W. ALLIN*
Bureau of Agricultural Economics

I

AT THE last National Agricultural Outlook Conference speakers were heard repeatedly making observations like the following:

- (1) "We do not engage in theoretical research, ours is the job of analyzing the facts in such a way as to provide practical guidance to farmers, farm organizations and other agricultural agencies "
- (2) "We use outlook information as a means of attracting attention and stimulating interest on the part of farm audiences so that we can then teach them economic principles."

Concealed in these two statements is a number one confusion in the minds of too many professional and academic economists. It is the purpose here to explain this confusion and to show some of its consequences, for practical theory is a generalization of means-consequence relationships that serves as an aid in determining a future course of action.

Why would any research economist ever say that he doesn't engage in theoretical research? And why would anyone think of the teaching of economic principles as a goal distinct from formulating a future course of action? Every scientific effort to analyze the facts so as to anticipate the future and guide action requires the use of a variety of concepts or mental tools. And an economic principle is an expected repetition of a past relationship that has practical significance for future action.

The only reason a research economist ever says he doesn't engage in theoretical research is to be found in the double meaning of the word "theory." It can mean either "pure" theory or "practical" theory. When he makes such a statement, the word to him means pure theory, which is "intellectual speculation without reference to practical application."¹ This is the same meaning as that implied by another economist who says that "the notion that economics is a science explanatory of behavior is the most important single con-

* This is to acknowledge constructive suggestions and criticisms from Howard L. Parsons, D. B. DeLoach and other colleagues and friends, especially those of the Graduate Seminar at the University of Wisconsin.

¹ Stated orally to the writer by Professor Ragnar Frisch, University of Oslo.

fusion in the methodology of the science."² Pure theory is logical reasoning from assumed premises. Such reasoning need not describe reality nor serve any useful purpose.

Practical theory, on the other hand, is a generalization that is developed as a basis for judgment with respect to action. It is a forecast of future consequences for the purpose of dealing with practical problems.³ Thus, two reasons exist for the persistence in popular discussion of a conflict between theory and practice: (1) The fact that theories never intended to have practical significance satisfy the purposes of the theorist, and (2) the fact that theories intended to serve practical purposes often turn out to be wrong.⁴ To deny any connection with the "theoretical" and to lay claim only to the "practical" is merely to disavow either a pure theory that happens to be useless for any kind of action or a theory that was intended to be useful and turned out to be a mistake. In other words, to be theoretical is not necessarily to be impractical.

If we can assume that those who would distinguish between outlook and the teaching of economic principles are interested only in practical theory or principles, they are really distinguishing between the kind of forecasting usually associated with outlook information and all other kinds of forecasting. The former is a set of conclusions concerning future prices, incomes and quantities based on an analysis of all the relevant collective influences. The latter, on the other hand, might include among other things the forecasting of an individual farmer's income under alternative assumptions as to how he might manage his own farm—given a set of forecasts regarding the collective influences. In either case, interest in teach-

² Frank H. Knight, *The Ethics of Competition*, p. 279.

³ "... Often the word theory, or theoretical, is a name of reproach uttered by the practical man who claims to be dealing only with Facts . . . But the practical man is a theorist when he predicts that the prices of stocks will rise and therefore buys as much as he can. If, instead, the prices fall and he is bankrupt, it is not because he is practical but because his theory was wrong. He did not analyze all the facts; . . . did not guide his practice by a correct theory. He was a poor theorizer. Hence the word theory means a correct or incorrect insight among the limiting and complementary factors. It is not a fact, but a prediction of facts. If correct, then it is an insight that will fit all the future facts needed. If not correct, then it is simply a blunder and needs correction." By John R. Commons, *Institutional Economics*, Macmillan Co., N. Y., 1936, p. 102.

⁴ But it should not be inferred that practical theory is necessarily impure, bad, or biased; or that pure theory is always useless for dealing with practical problems. The search for "truth for truth's sake" has turned up ideas that later proved to be of very great practical importance. The intention is only to point out that the difference in meaning of the two concepts is so great that the interchangeable use of the word "theory" to convey both meanings is a constant cause of confusion.

ing "principles" might refer only to teaching the "why" of the conclusions developed, so as to give the farmer a proper degree of confidence in them—to avoid a tendency on his part either to take them on faith or to ignore them entirely.

II

Now I have been told by some of my colleagues that any discussion of ambiguities such as those referred to above would be trite so far as most economists are concerned—that it would be a discussion of the obvious. Perhaps so. Yet, it is difficult to escape the conclusion that it is precisely this *failure to distinguish pure theory from practical theory that has resulted in a widespread tendency among economists to apply pure theory to practical problems without making necessary allowances for the premises of such theory*. Untenable conclusions and inferences are reached because the "analytical model" or theory is not fitted either to the facts of the problems or the purposes of the analyst. One of the most persistent sources of fallacies arising from this practice is the indiscriminate use of the "pure competition model" of equilibrium theory in agriculture. And some of the most conspicuous examples to occur recently have been discussions of the "malallocation" of resources and the "inefficiency" of American agriculture.⁵

When economists undertake to compare the efficiency of agriculture with that of industry, or to form some judgments concerning the allocation of resources within agriculture or as between agriculture and industry, they have to decide first what they mean by efficiency, what resources they are talking about, and what their standards are for changing their allocation. The definitions and standards they choose are determined by the purposes they have in mind.⁶ If their purpose is merely to engage in an exercise in

⁵ Theodore W. Schultz, "How Efficient is American Agriculture," this *Journal*, August 1947.

⁶ It is often said that one definition is as good as another provided we use it always with the same meaning. But is this so? Each definition must be fitted to the purpose we have in mind. If our purpose is simply to "speculate"—to find universal, timeless, and absolute "truth"—we can use a pure theory definition and always use it with the same meaning. If this definition were used consistently, the practical man would be told at the outset not necessarily to expect any identity between theory and practice. But if our purpose is to understand and deal with a practical problem, the meaning we give the term must fit that purpose. We must define theory as "mental tools useful for dealing with practical problems." Under this definition, "mental tools" that turn out to be useless in practice are bad theory—at least for the purpose at hand.

logic, it makes little difference what definition or standards they choose, so long as everything they say is logical. But when the practical implications of their analyses are. (1) That American agriculture is inefficient; (2) that resources are more badly allocated in agriculture than in the rest of the economy; and (3) that the economy generally would be more efficient if it functioned in conformity with the pure competition theory—when these are the implications of their reasoning, my reply is they had better examine the criteria by which their judgments were reached.

III

First, let us consider the conclusion that American agriculture is inefficient. This conclusion is derived by arbitrarily selecting for the meaning of "efficiency" the meaning associated with pure competition theory, and then implying that others either do mean or should mean the same thing when they say American agriculture is efficient.

This pure competition meaning of efficiency is, "When all resources in the economy are allocated so that no further gain can be achieved by an additional transfer of a factor or product from one use to another use, 'maximum economic efficiency' is achieved. This would represent the ideal, the general equilibrium of economic analysis."

It is recognized, of course, that there are other meanings of efficiency such as output of corn per acre of land, per man hour of labor, etc. But these are called "technical" rather than "economic." Yet, it is precisely these so-called technical meanings that others have in mind when they say American agriculture is efficient. And they cannot be proved wrong by implying that they should mean something else. No evidence has ever been presented to show they are wrong if the term "efficiency" is given the same meaning as they attach to it.

Under the pure competition model, it is possible to identify *rate* of output per unit of comparable input with *value* of output per unit of comparable input by the assumption of equilibrium. When the economy is in equilibrium, goods exchange in proportion to the marginal *dollar* cost of producing them. This becomes identical with marginal *labor* cost because it is assumed that comparable labor can and does flow promptly from one employment to another so that at equal rates of pay there is no discrepancy between dollar

cost and labor cost. But this is all pure theory and requires drastic modification for practical use.

When the pure competition theorists talk about "economic inefficiency" of American agriculture, they do not mean a low *rate* of output per unit of input; they mean "waste" of resources, largely of manpower. They mean that some agricultural labor either is used to produce goods that are less wanted than other goods or is not used to produce any goods—in *which case it never becomes "input."* They mean that agriculture is "inefficient" because it adopted "gadgets" and "improved farm management" faster than it reduced its birthrate, and that the resulting surplus farm population has failed to go to town to make more "gadgets." They mean that agriculture is "inefficient" either because its *total* output of agricultural products has been too great or because too large a total of agricultural labor is producing nothing.

That these conditions exist among the rural population is in no sense an "agricultural" phenomenon as such, nor is there any evidence to suggest that over any business cycle any larger proportion of available manpower is unemployed or underemployed in agriculture than in the rest of the economy. Economic efficiency in this sense is "double-barreled" and applies to the whole economy, the nonagricultural as well as the agricultural segments. It not only refers to the aggregate output of all goods and services, but also to the "proportioning" of that output as between the different goods and services. Under the first meaning, a given economy might be more "efficient" than another because it works longer hours rather than because it is more effective per hour. And under the second meaning, relative prices can be used as a measure of a "proper" proportioning only under the twin assumptions of pure competition and virtuous human beings. If any "moral" value whatever attaches to this meaning, it is more than doubtful that the economy would be more "efficient" if some of the boys and girls from our more efficient Iowa farms moved to town to become bartenders and barmaids merely because they could make more money at these occupations.

In any event, no such tortuous reasoning is required to recognize the obvious fact that at least since the Civil War there has been chronic involuntary underemployment and unemployment of manpower in the South. This is the consequence of a complex of social, political, racial and economic issues that cannot be treated by

merely referring to it as the "cake of custom." Actions on the civil rights and educational fronts must at least accompany those on the "economic" fronts. It is not an "agricultural" phenomenon as much as it is a "social" phenomenon. It is "dichotomous" mal-allocation in the sense that it refers to both farm and nonfarm populations.

The tendency to think of it as "agricultural" rests on an assumption that either relatively or absolutely more labor power on farms than off farms is "wasted." If this is true, the evidence to support it is far from conclusive. And even if it were a demonstrated fact, it would have nothing to do with the question of agricultural efficiency as a rate of output. There is no more reason for counting the unused or underused labor on farms as agricultural "input" in calculating the agricultural efficiency ratio than for counting it as manufacturing input in computing the industrial efficiency ratio. For "social" reasons it is not input for either agriculture or industry. All of which suggests the need for explaining another fallacy that logically follows from uncritical use of pure competition theory—that a purely competitive society would be more efficient than the one we now have.

IV

This, again, may be a "valid" conclusion if the assumptions of pure competition theory are granted, but it is not "true" in any practical or pragmatic sense. When an economist implies that it is true as well as valid he is living in the last century when the assumption in classical doctrine that the productive resources of capital and labor were so fluid that they flowed readily from one profit-making opening to another was more nearly supported by observable facts than it is today. It is much less true today of a large part of American industry, where mass-production methods have led to the creation of great units which alone can exploit the new technology. If one believes that our economy as a whole is more efficient because of this kind of exploitation of modern technology, one cannot at the same time believe that "atomistic" competition would be most efficient. To do so, would be to believe in the "fallacy of nonconcomitant or inaccessible options." Even if the ideal of substantially pure competition were attainable or accessible, one cannot hope to enjoy its benefits at the same time

he enjoys those of mass production "fair" competition. In plainer words, we cannot have our cake and eat it too.

If our national policy of fostering "reasonable" competition in order to realize the "social" benefits of modern technology—a policy affirmed by a long succession of Supreme Court decisions—is our deliberate choice, we must expect both the continued existence and the periodic recurrence of substantial "pockets" of "wasted" manpower. That is, we must expect it until these pockets become so large as to be unmanageable. The Maximum Employment Act of 1946 is recognition of the necessity for keeping them manageable. Under pure competition, of course, there would be no need for such measures.

The "social" costs of the policy we are following include our various social security measures, minimum wages for labor, parity prices for farmers and many others. We should do everything possible to eliminate these pockets of underemployed and unemployed manpower, but it would be something less than realistic to believe this can be done in conformity with the pure competition model—unless we are prepared to sacrifice at the same time the advantages of mass production technology with its inevitable accompaniment of "administered" prices.

Herein also lies a fallacy of all "forward" price proposals involving "equilibrium" prices and compensatory payments—at least so far as the allocation of manpower between agriculture and industry is concerned. If the compensatory payments were "fair" they would be higher to low-income farmers than to high-income farmers, and they would tend to remove the economic pressure on such farmers to migrate to nonfarm employments. Within agriculture, of course, resources will tend to be allocated in accordance with the "pattern" of prices, at least to the extent that agriculture is actually competitive. But even here prices alone cannot be depended upon to do all that is needed or desirable. They will be effective only where both the *opportunity* for choices and the *willingness and ability* to make choices exist.

To say that agriculture is less efficient than industry because the *value* of output per man in agriculture is less, is precisely like saying that schoolteachers are less efficient than bricklayers because they receive fewer dollars per person. And to say that American agriculture is inefficient is to imply that it can be made more efficient.

Any realistic discussion of improvements in efficiency must take into account the available alternatives. Unless this is done, any talk about inefficiency is mere words without meaning. Practical public policy can never be derived by "comparing the idealized conditions . . . and actual circumstances . . . and developing the necessary positive steps required to eliminate the discrepancy."⁷ Excessive preoccupation with the "ideal" is the usual consequence of formal model or pure theory approaches to public policy. An *attainable ideal* is always the *best available choice*. The principles by which action with reference to choices is formulated is practical theory.

In summary, then, theory is of two kinds: Pure theory and practical theory. When the lessons learned from pure theory are incorporated into practical theory, full account must be taken of the *assumptions* underlying the pure theory and appropriate adjustments should be made therefor. If this had been done by those currently discussing the "inefficiency" of American agriculture and the malallocation of resources in agriculture it is more than doubtful that they would have arrived at the conclusion that American agriculture is inefficient, they probably would not have implied that resources are more badly allocated in agriculture than in the rest of the economy, and they would not have left the impression that they think a freely competitive economy is more efficient than our "administered price" or "reasonably" competitive economy. If their purpose was to deal with some of the practical questions raised by these issues, they would have chosen definitions of terms to fit that purpose. For practical theory is not the mere logic of mathematics which is the language of numbers; it is also the *meanings* of words.

Karl Mannheim, in his *Ideology and Utopia*, clearly describes the causes of the theory-practice conflict when he says, "The fact that sciences are cultivated in academic surroundings constitutes a danger in that the attitudes adequate to the understanding of an actual sector of human experience are suppressed in the contemplative atmosphere which prevails in academic institutions. Today we almost take it for granted that science begins when it destroys our original approach and replaces it by one which is foreign to living experience. This is the most important reason why practice

⁷ D. Gale Johnson, *Forward Prices for Agriculture*, The University of Chicago Press, 1947, p. 11.

cannot profit by this kind of theory. This creates a tension between theory and practice which is increasingly aggravated by modern intellectualism. Summing up the main difference between this contemplative, intellectualistic point of view and the living standpoint which is accepted in the realm of practice, we might say that the scientist always approaches his subject-matter with an ordering and schematizing tendency, whereas the practical man—in our case the political person—seeks orientation with reference to action. The desire for concrete orientation leads us to view things only in the context of the life-situations in which they occur. A schematically ordered summary tears apart the organic interconnection in order to arrive at an ordered system which, although artificially constructed, is nevertheless occasionally useful.”

ACTUARIAL STRUCTURES FOR CROP INSURANCE

HAROLD G. HALCROW*
Montana State College

CROP insurance is conceived as a device which can be used by a farmer to stabilize his income against partial or complete crop failure to the extent that this failure is due to adverse weather or to related adverse physical crop conditions which are beyond his control. As such a device, or with various modifications, crop insurance has been tried in every major country in the world. The forms, coverages, and general provisions have varied widely. In some cases, the attempt has been made to provide general protection against any or all factors which cause low yields. At other times protection has been restricted to specific risks such as hail, flood and insect damage.

The method of sponsorship or of financial support has varied. In the United States until the passage of the Federal Crop Insurance Act in 1938 all attempts at crop insurance were by private companies. But in other countries crop insurance nearly always appeared under government sponsorship. In most cases it has been offered to farmers as a voluntary contract. In some other cases, notably in Japan and in the U. S. S. R., it has been compulsory. In the Canadian prairie provinces a compulsory wheat tax plan having some insurance features has been in operation since 1939. In the United States the Federal Crop Insurance Act passed in 1938 offers the outstanding example of an attempt to apply a voluntary crop insurance plan over a wide area.¹

* This paper presents some of the principal findings and conclusions which are contained in my Ph.D. dissertation, "The Theory of Crop Insurance," which was submitted to the University of Chicago in 1948. I am grateful for the assistance and suggestions given to me by several of my colleagues. I particularly wish to express my appreciation to D. Gale Johnson who, as chairman of the dissertation committee, gave me valuable advice in the development of the dissertation; to T. W. Schultz who encouraged me to proceed with my original suggestion and who carefully reviewed this paper, to Milton Friedman whose rigorous criticism helped me to improve my dissertation manuscript; to Rainer Schickele, M. M. Kelso and G. E. Korzan who have given me the benefits of their comments in reviewing this work. Several other friends and associates have helped me by their appraisal of certain points.

¹ A large number of studies of crop insurance, of a comprehensive and empirical nature, are available. Some of the recent articles which have been found most enlightening are: F. Arcoleo, "Crop Insurance," *International Review of Agriculture*, Rome, International Institute of Agriculture, XXXI (1940), 271-76E, 306-16E; J. C. Clendenin, "Federal Crop Insurance in Operation," *Wheat Studies of the Food Research Institute*, XVIII (1942), 227-90; Dale E. McCarty, "Wheat Yield Insur-

In spite of rather general and enthusiastic support of the idea of voluntary crop insurance and in spite of strenuous efforts to establish such programs, in almost every case voluntary crop insurance plans have failed on at least one of two counts. Either they have failed to attract the large majority of farmers or they have failed to approximate a self-supporting situation.²

The failure to attract participation of the majority of farmers suggests that many farmers have not looked with favor on the premium-indemnity schedule and may have considered that they could maximize their income over time by remaining outside the program.³ The failure of the plans to become self-supporting suggests that adverse selectivity must have been widespread, farmers with better than average expectations of collecting indemnities being the ones most frequently attracted to the program. This failure of voluntary crop insurance raises two basic questions: Is it possible to design and to administer these programs so that they will be attractive to the large majority of farmers and so become self-supporting? Or will it be necessary, in order to obtain widespread participation, to turn to compulsory insurance or to insurance that is heavily subsidized? A strong case may be presented

Pengra, "Crop Production in the Semi-Arid Regions on Insurable Risk," this *Journal*, XXIX (1947), 567-70; President's Committee on Crop Insurance, *Report and Recommendations of the President's Committee on Crop Insurance*, House Document No. 150, 75th Congress, 1st Session, 1937; B. D. Raskopf and E. B. Fickle, *Cotton Crop Insurance in Tennessee and United States*, University of Tennessee Rural Research Series, Monograph No. 198 (1946); Raskopf and Fickle, *Wheat Crop Insurance in Tennessee and United States*; *ibid.*, No. 197 (1946); F. H. Sanderson, "A Specific-Risk Scheme for Wheat Crop Insurance," this *Journal*, XXV (1943), 759-76; Andrew Stewart, "Stabilization of the Income of the Primary Producer," *Canadian Journal of Economics and Political Science*, XI (1945), 359-72; S. E. Wrather, "Adaptation of Crop Insurance to Tobacco," this *Journal*, XXV (1943), 410-18. Since 1937, extensive congressional hearings have been held on the subject of crop insurance. Several issues of *The Agricultural Finance Review* and *The Agricultural Situation*, published by the United States Department of Agriculture, have carried short articles on this subject.

² Exhaustive study of the references listed in the preceding footnote and other source material serves as background for this statement. Experience of the Federal Crop Insurance Corporation (hereafter abbreviated as FCIC) may be cited as an example. The crop year 1947 was the first time that premium collections of the FCIC exceeded indemnity payments on combined operations for all commodities. In this year, however, wheat acreage insured was 72 percent of total acreage insured among all crops, and wheat yields generally were well above average. Up to 1947, the losses incurred in the writing of insurance totaled about 90 million dollars in addition to operating expenses paid for by current appropriations. At the height of participation in the wheat program in 1940 about 20.7 percent of the seeded acreage of wheat in the United States was insured.

³ Cf. Clendenin, *op cit.*, pp. 260-61.

for compulsory crop insurance or for insurance involving subsidy.⁴ Compulsory crop insurance, however, may be resisted by farmers on social-political grounds and on the grounds that premiums, at various times, would exceed the discounted value of the probable indemnity. Insurance involving subsidy also may have important adverse effects on the efficiency of resource utilization.⁵ Therefore, a voluntary contract not involving substantial subsidy is to be preferred.

Forms of Voluntary Insurance

In the discussion which follows, the forms which voluntary crop insurance plans may take are outlined; and the conditions necessary to establish a crop insurance program to meet actuarial requirements are examined. Such a program is defined as fulfilling the following conditions: (1) It would protect a farmer against partial or complete crop failure, to the extent that this failure is due to the adversity of weather and related physical crop conditions beyond his control, and (2) protection would be offered under such a premium-indemnity schedule that all farmers facing similar probabilities for indemnities would be assessed similar premiums. Fulfillment of the latter provision would mean that no farmer would be penalized or subsidized consistently through the use of insurance. Under this condition, the insurance contract could be attractive to any farmer who wished to reduce the income uncertainty caused by fluctuating physical crop conditions and it could be designed to eliminate the necessity for recurring subsidy due to indemnities continuing in excess of premiums.⁶

⁴ For the line which the argument for compulsory insurance might take, see A. C. Pigou, *The Economics of Welfare*, London: Macmillan and Company, 1920, pp 902-11. The subsidy which would bring about the widespread use of crop insurance on a non-compulsory basis might be considerably less than the amount of money which has been spent on feed and seed loans, direct relief payments, disaster payments, etc.

⁵ It might encourage the growing of wheat on land which is "sub-marginal" for wheat production, for instance. Thus it might cause a misallocation of resources toward wheat production. Some cases have been found where flax growing was encouraged by insurance on land on which flax would not be grown in the absence of insurance. Incidentally, feed and seed loans or direct relief may be protested on similar grounds. Too many resources may be funneled into an area in relation to marginal productivity of the land in the area.

⁶ Only experience can determine what proportion of farmers would buy such insurance and what size reserves an insurance corporation should carry. There can be little doubt but that an actuarially sound program in the United States would have paid several billion dollars to farmers during the drouth period of the 1930's if a large majority of the farmers of the United States had been insured. Also during

The analysis is restricted to three different plans for crop insurance distinguished by the methods by which premiums and indemnities are calculated. These three plans are called all-risk crop insurance, area-yield insurance, and weather-crop insurance. The conclusions, which may be applied generally, are stated with reference to the United States.

All-risk crop insurance. In all-risk crop insurance a base yield is established for each farm—such as the average yield experienced on that farm in a 10-year period. Insurance is offered to cover either 50 percent or 75 percent of the base yield. If the actual yield in any year falls below the insured yield, an indemnity, equal to the difference between insured yield and actual yield is payable to the insured farmer. Premiums are assumed to be uniform over a county and are based on an estimate of the average indemnity payable in the county over a period of years.⁷ For example, if a farmer's average yield of wheat for a 10-year period were 20 bushels per acre, his insured yield at the 75 percent level would be 15 bushels per acre. If he received 10 bushels per acre some year his indemnity for that year would be 5 bushels for each acre insured.

Area-yield insurance. In the area-yield insurance plan, premiums and indemnities are based on the yield received in an area of normally uniform crop conditions which may vary in size from a township or part of a township to a county or more. Indemnities are paid to any insured farmer in any year in which the mean area-yield for the year falls below a specified level (the level may be defined as some percentage of the expected or normal yield for the

the years from 1941 to 1948, aggregate premiums would have exceeded indemnities by several billion dollars. Aggregate gains vs. losses in any year or over a period of years should not be used as the criterion of success or failure in a crop insurance program. Instead, the analysis must distinguish between the losses which may be due to incorrect actuarial procedure and those which may occur from time to time because of adverse crop conditions.

The use of a compulsory contract is not ruled out in this analysis. Insurance might be made compulsory in some areas through operation of a crop insurance district which might be established under a "crop insurance district law" much as weed districts are now established under a "weed district law." Also lenders might require the use of insurance as a condition for extension of credit. But under any case the first task is conceived as one of perfecting the actuarial structure.

⁷ The FCIC attempted to establish an individual premium rate for each farm based on the probabilities of indemnity for that farm. After a few years' trial it was decided that this method was not practical because of inaccurate or inadequate data and by 1946 nearly all crop insurance in the United States was sold under uniform county-wide premium rates. In 1947 in Chouteau County, Montana, for example, the county-wide premium rate for insuring winter wheat on summer fallow for 75 percent of the base yield of the farm was 1.8 bushels per acre.

area). For example, if the normal yield of wheat of an area were 20 bushels per acre, if the yield in a given year were 16 bushels per acre, and if the insured were a wheat farmer insuring for the normal area-yield, he would receive the equivalent of four bushels of wheat for each acre he insured regardless of his wheat yield on his farm. If he were insured for 90 percent of the normal area-yield his insured level would be 18 bushels per acre and his indemnity would be two bushels per acre. All farmers in an area would be offered a common schedule for insuring area-yields which would offer options of insuring for normal area-yield, for 90 percent, for 80 percent, and on down to about 50 percent of the normal area-yield. Corresponding to this schedule there would be a schedule of premiums specifying the premium to be charged per acre. The premium rates would be based on the estimated amount of indemnities payable under each of the indemnity options.

Weather-crop insurance. In the weather-crop insurance, premiums and indemnities are based on the weather records of the locality in which insurance is to be sold. Indemnities would be paid to any insured farmer in any year in which the weather, in terms of some measureable criterion, is beyond certain limits of tolerance. For example, if the mean annual rainfall in an area were 25 inches, which is assumed to be near the optimum for crop production in this case, a farmer might wish to insure against the possibility of occurrence of less than 18 inches or more than 32 inches of rainfall. He may be offered an indemnity schedule showing the indemnity he would receive providing mean annual rainfall is 17 inches, 16 inches, 15 inches, or less, and 33 inches, 34 inches, or more. Additional schedules could be provided for farmers who wished to insure against the probability of rainfall being less than 20 or more than 30 inches, less than 16 or more than 34 inches, and so on. For each schedule, a definite premium would be assessed. The premiums and indemnities could be stated in terms of amounts of produce or money for an insured acre. Factors in addition to rainfall such as temperature, evaporation, or hail might be included in the formula.

The process of analysis which follows is (a) to apply stated assumptions to each of the forms of crop insurance, and (b) to relax these assumptions one at a time, observing the effect of this relaxation on the respective crop insurance program.

All-Risk Crop Insurance

Basic assumptions. The first assumptions are (1) that the secular trend value for yields on each farm in a county is zero, (2) that the average deviation of yields from the mean is the same for all the farms, and (3) that the mean yield is the same for all the farms. If these assumptions are realized the premiums paid by a farmer using all-risk insurance should be equal to indemnities over a long period of time.⁸ No net gain or net loss should be experienced. The effect of such insurance would be to reduce the fluctuations in income caused by yield variations.

As the first assumption listed above is relaxed, it is assumed that the level of yields changes on individual farms. Under the new assumption, farmers with increasing yields would find that the aggregate premiums for a 15- or 20-year period would be in excess of the sum of the indemnities and conversely for farmers with decreasing yields. Without some compensating device, the first group of farmers would have net losses and the second group would receive windfall gains through the use of insurance.

The use of a moving average as the base for insured yield and use of a system of dividends for farmers with low indemnities might reduce the inequities otherwise found in the upward or downward trend. The system of dividends could not eliminate the inequity completely, however, because of the lag inherent in the adjustment. A more serious criticism which applies to the use of a moving average is that insured yields would not be consistent with yield probabilities. After a series of poor yield years on an individual farm, for instance, insured yields would be reduced to the point where a farmer should drop the insurance.⁹ After a series of good years the insured yield might be so high that the farmer would have a good chance of obtaining a windfall gain if he should continue with in-

⁸ This would be true under the condition that administrative expenses, or loadings, are paid by the Federal Government. If administrative expenses are paid out of premium receipts, then gross premiums, equal to net premiums plus loadings, would be equal to aggregate indemnities. It is a matter of policy, which is not examined at this point, whether administrative expenses should be paid out of gross premiums or be paid by the Federal Government. The latter is assumed but this assumption does not appear as a necessary condition in the analysis.

⁹ In many counties in Montana, the Dakotas, Nebraska, and Kansas, poor crops were experienced in 1940 and 1941. The FCIC raised premium rates and cut insured yields on the basis of this experience at the same time that prospects appeared good for the 1942 crop. As a result participation declined sharply, Cf. Clendennin, *op. cit.*, p. 261.

surance. Under such conditions an adverse selectivity is probable ¹⁰

When the second assumption is relaxed and it is assumed that the average variation of yields is not the same for all farms, the farmers having the larger yield variations would receive larger indemnities in years of poor crops than those farmers with smaller yield variations. The difficulty of working out an individual actuarial schedule for each farm which would reflect this situation is readily apparent from a study of farm yield data. Even if this could be done the desirability of doing so is questionable because a series of unusually wide yield variations on a farm, or a series of low yield variations, might cause the calculated indemnity probability to be at variance with the actual yield probability.

The individual farms in a given area may differ widely in respect to average yields.¹¹ When the third assumption is relaxed various degrees of the following situations may develop. If the actual deviation from the mean yield in bushels or pounds is the same for all farms, the farmers with low average yields would receive indemnities more often and in larger amounts than the farmers with higher yields.¹² If the deviation of yields in terms of percentage of mean yields is the same for all farms, the farmers with the higher average yields would receive larger indemnities in poor crop years than the farmers with low average yields. In order for there to be no inherent cause for an adverse selectivity, the indemnity for

¹⁰ Under this condition an adverse selectivity could develop through time independently of the type of adverse selectivity which might develop among a group of farmers in any particular year. It should be noted that the use of early deadlines for insuring or of a "continuous" contract could not completely overcome this difficulty. Early deadlines have been recommended elsewhere. See Clendenin, *op cit.*, pp 248-50. In 1946 the FCIC instituted a "continuous" contract which would be subject to annual cancellation by either the farmer or the corporation. A three-year contract was being used for wheat. See *Agricultural Finance Review*, IX (1946), 71.

¹¹ The following data are presented for all farms on the AAA listing sheets in Chouteau County, Montana, to indicate the wide range in yields which may exist in some cases:

Average Yield 1925-32 Bushels per Acre	No. of Farms
0-5	212
5 1-10	496
10.1-15	320
15 1-20	126
20.1-25	64
Over 25	51
Total	1,269

¹² This conclusion is valid only under the condition that farmers insure for less than their mean yield, say 75 percent of mean yield or less

each class of farmers ranked according to yield would have to be potentially equal for the entire universe of farms which were eligible for a common premium rate. The fulfillment of this condition appears to be out of the question.¹³

Effect of increasing accuracy of farmers' expectations If farmers grow more than one crop and if they vary the acreage of crop to be insured from year to year, an additional factor involving adverse selectivity may appear. In years when yield prospects are relatively poor, the discounted value of the crop in terms of expectations will be greater for an insured crop acre than for an uninsured acre. In years when yield prospects are relatively good, the opposite case will exist because the insurance premium will appear as a cost and the net discounted value of the crop in terms of expectations will be less for an insured crop acre than for an uninsured acre. In the former case, therefore, there would be a tendency on the part of the farmer to increase the insured acreage and in the latter case there would be a tendency to reduce the insured acreage. If insured acreage on a farm can be varied, the tendency for an adverse selectivity to develop would depend on the extent to which crop yields can be predicted prior to seeding.¹⁴

Two factors may enter into the farmer's yield estimate: (1) general weather conditions, soil moisture, insect conditions, etc.,

¹³ There may be a tendency toward the fulfillment of the condition although the relationship might be termed highly haphazard. If the standard deviation of yields is higher on high yielding farms than on low yielding farms, and if the coefficient of variability is greater on the low yielding farms than on the high yielding farms, there would be a tendency toward fulfillment. There is some evidence that such a tendency does exist. The following data, for example, are from a study conducted at experiment stations in the Northern Great Plains during the years 1906-1935 and the data refer to yields per acre of spring wheat:

Eight high yielding stations. $\bar{X}=16.9$ $\sigma=10.8$ $V=64$

Five low yielding stations. $\bar{X}=11.9$ $\sigma=8.9$ $V=75$

See John S. Cole, *Correlations Between Annual Precipitation and the Yield of Spring Wheat in the Great Plains*, Washington USDA Technical Bulletin 636 (1938), pp. 26-28.

It should be noted that the above is one of the causes of adverse selectivity cited which could be avoided by the establishment of an individual premium rate for each farm. The establishment of individual premium rates has been found "impractical," however, because of inaccuracies in individual farm yield data and because of the changes which have occurred in the normal level of individual farm yields. Cf. (above) footnote 7.

¹⁴ In the Great Plains, the ability to predict yields prior to seeding or in the spring appears to be increasing through the use of information obtained from recent investigations. See A. L. Hallsted and O. R. Mathews, *Soil Moisture and Winter Wheat with Suggestions for Abandonment*, Kansas Agricultural Experiment Station Bulletin No. 273 (1936) and Ray F. Pengra, "Crop Production in the Semi-Arid Regions and Insurable Risk," this *Journal*, XXIX (1947), 567-70. Cf. (below) footnote 21.

and (2) individual tilth condition of each individual field. The insurer might prevent an adverse selectivity from developing on the basis of the first factor by providing only a long term contract and by writing insurance for a definite number of acres each year. It would be practically impossible to prevent an adverse selectivity from developing on the basis of the second factor because under any kind of contract that might be written it would be necessary to allow a farmer freedom to insure part but not all of the various fields in his farm. The rational thing for a farmer to do would be to place insurance on those fields on which the probability of indemnity is relatively high. If all farmers have an equal opportunity to select fields in this manner, no adverse selectivity would result among farmers and premium-indemnity rates could be made to reflect such a situation, but a conclusion based on general observation is that farmers do not have an equal opportunity to make such choices. Some will have relatively poor yield prospects on some fields in particular years in comparison with yield prospects of some other farmers. The former group may choose to insure the fields on which there may be a high indemnity probability in comparison with the maximum indemnity probability of the other farmers. A larger proportion of the former group than of the latter group may enter the insurance program.

General conclusion. Thus, relaxation of each of the three assumptions first stated—and they must be relaxed in order to consider the conditions in some of the major agricultural regions of the United States—and interjection of the idea of increasing accuracy of farmers' yield expectations, leads to a situation implying adverse selectivity, a type of adverse selectivity which cannot be overcome by modifying the provisions of all-risk crop insurance. Therefore the general conclusion in respect to the all-risk type of crop insurance is that it will work in a satisfactory manner only under a system of conditions so exacting in their specifications that they will be found to rather limited extent in American agriculture. In some low-risk regions, in some areas where yield trends are not pronounced or are not influenced to a marked degree by the action of the individual farmer, and in case of some crops such as perennial fruits, the all-risk insurance may work in a satisfactory manner. But all-risk crop insurance may fail to work satisfactorily over the major part of the farming area, particularly the highest risk area, of the United States.

Area-Yield Insurance

Necessary condition. The basic empirical assumption used in developing the area-yield type of crop insurance is that the mean yield in a year in an area will reflect the physical crop conditions faced by a farmer in the area. While this assumption is not in the form of a necessary condition for the insurer, who may be indifferent in an actuarial sense whether it is fulfilled or not, it represents a condition which must be fulfilled to some degree if a farmer is to receive protection against the occurrence of adverse crop conditions. One method for determining when this condition is fulfilled in an area is to measure the degree of consistency with which each individual farmer's yields vary directly with the area yield. This degree of consistency will depend, to a considerable extent, on the boundaries established for the area and on the homogeneity of the area in production of the crop insured.¹⁵ The closer the correlation between farm and area yields, the more effective area-yield insurance will be in providing the equivalent of yield stability for a farmer in the area.¹⁶ It is not possible on an a priori basis to determine to what extent this correlation exists. Among some two hundred farm cases which have been studied, it would have been possible through the use of area-yield insurance to have reduced the average deviation of gross income on the individual farm, which was due to variations in yields, to a level varying from 20 to 40 percent of what the average deviation of gross income was in the absence of insurance.¹⁷ The average deviation of net income

¹⁵ The ideal area concept to employ in an area-yield insurance program might be that of a type-of-farming area which may be defined as an area within which a particular system of farming is dominant or within which two or more systems are interwoven into a pattern. Within any one area the same pattern of change should exist and the boundaries should be moved when there are changes in ecological factors. Cf. John D. Black, Marion Clawson, Charles R. Sayre, and Walter W. Wilcox, *Farm Management* (New York: The Macmillan Company 1947), pp. 384-86. Type-of-farming studies in which areas have been delineated have been completed and the results published in bulletin form for several states, among which are the following: Connecticut, Illinois, Indiana, Iowa, Kansas, Kentucky, Michigan, Montana, North Dakota, South Dakota, Texas, Utah, and Washington.

¹⁶ These correlations are a matter for empirical analysis. When the correlation is found to be high it may be concluded that there is a close relationship among area yields and crop conditions faced by the farmer. A low correlation does not prove that this relationship does not exist, however, because a lack of correlation might be caused by differences in a farmer's methods or practices.

¹⁷ This is a greater reduction than is possible under similar circumstances with the use of the 75 percent yield coverage under the all-risk type of crop insurance. This result was obtained using the assumption that premiums would be paid only in the years when area yield was above average. The yield data were taken from records of wheat farms in Montana, North Dakota, South Dakota, Kansas, and of cotton

could have been reduced to a greater degree. The extent to which similar results could be experienced would determine how effective area-yield insurance should be in providing the equivalent of yield stability for a farmer. The studies which have been made indicate that this range of effectiveness may be significantly greater than has been possible with all-risk crop insurance.

General analysis. In performing an actuarial test of area-yield insurance the first assumptions are: (1) that the secular trend value for yields on each farm is zero; and (2) that the average deviation of yields from the mean is the same for all farms. If these assumptions are realized, and if the necessary condition stated above is fulfilled, area-yield insurance would materially reduce or perhaps eliminate the income fluctuations of a farmer which are caused by yield variations. Net premiums paid by a farmer would equal indemnities received over a long period of time.

If the yield level changes on individual farms, any farmer would find that the change in his own yield level would have no effect on his own premium-indemnity schedule, except as his own yield affects the area average. The insurer may be indifferent therefore about the yield trend on any individual farm because all farmers in the area would participate in a common premium-indemnity schedule. This means that a farmer with increasing yields would not be penalized by the use of insurance and that a farmer with declining yields would not receive windfall gains through the use of insurance. A farmer would be able to reap the full gain from any improved farming practice which resulted in higher yields and a farmer who received low yields because of his own malpractice would not be subsidized.¹⁸

The weighted average yield experienced in an area each year

farms in Texas. Yields of tobacco farms in Virginia did not show as high a yield correlation. Lloyd Barber of the BAE, John Fulmer of the University of Virginia, and J. A. Hodges of Kansas State College helped to provide some of these data. These cases should be regarded as illustrations of what may be done rather than proof of the extent of area yield insurance applicability. Further refinement in area delineation should make possible closer correlations between farm and area yields and this should increase the effectiveness of area-yield insurance in providing the equivalent of yield stability.

¹⁸ It is extremely unlikely that farmers would ever resort to "collusive action" in an area to deliberately lower the area yield and thus obtain an indemnity (1) because to do so would lower the normal area yield and thus provide no long term gain and (2) because the leaders in the action would be the losers. Farmers who did not "go along" would obtain an equal indemnity as well as their regular crop. There would have to be 100 percent "collusion" for the leaders of such action to break even.

would be used in determining the eligibility for indemnity of all insured farmers. The statistical problem is twofold: (1) to establish the weights to use in an area in deriving the area average; and (2) to measure the yields in the various parts of the area each year in order to determine the area average for the year. Each year yields would be measured on a group of typical or "base" farms in each part of the area. These data would be combined to provide the weighted area average. If these farms were "well" selected, perhaps as few as 15 or 20 farms could be used to provide the necessary data and the results might be made to apply to 1,000 farms or more, depending on the size of the area and on the character of the agriculture in the region.

The normal area-yield would be an average of the weighted area yields experienced over a period of years modified to reflect the effect of changing costs and prices and changing farm technology. The normal yield would be the expected yield under normal weather conditions, and the normal yield would be changed from time to time so that insured yield and premium rates would reflect the changes in the level of yield probabilities. If this is done the insurer may be indifferent about the trend of yields in the area or among farmers in the area.

The statistical problem involved is that of developing the average of the weighted area yields and of developing the necessary "production functions," related to prices, costs, and technology, which would be used in modifying the base average to obtain the normal yield for the area.¹⁹ In order to prevent intermittent participation which might develop into an adverse selectivity it would be necessary to take account of cost and price expectations of farmers. Otherwise farmers might estimate area yields a year or two in advance with greater accuracy than would be inherent in a

¹⁹ The establishment of the premium-indemnity schedule may require successive approximations. Ten years for instance may be too short a period for the establishment of a base area yield. Cf. V. P. Timoshenko, "Variability in Wheat Yields and Outputs," *Wheat Studies of the Food Research Institute*, XIX (1943), 196. It should be recognized that changes in insured yields and in premium rates should also be based on factors such as changes in farming practices, in seed, and in use of fertilizer. The same method could not be applied in all-risk crop insurance (1) because an agency not directly associated with the management of an individual farm is not in position to determine yield probabilities on individual fields with the same degree of accuracy as the farmer and (2) because changing farming practices may make all computations of past performance meaningless. An individual farmer might change his mind about applying fertilizer thus changing the yield probability for the farm or field.

formula used by the insurer; and they might buy insurance heavily when yields are expected to be lower than the formula indicates and drop out of the program when they expect the area yield to go above that indicated by the formula.²⁰ If their expectations are correct and if the terms of the contract allow them to act in this way it is possible that an adverse selectivity might result.

Various devices might be used to overcome the possibilities of such an adverse selectivity. The freedom of individual farmers with respect to insurance might be restricted by charging an initial entry fee and a re-entry fee adjusted to prevent intermittent participation. Under some circumstances these fees might be refundable. A long-term contract—a three-, four-, or five-year contract for instance—with early deadlines for application and cancellation might be the only kind offered. Such action would be of an economically coercive nature, however, and perhaps could be justified only if the formula could not be refined to reflect the factors on which yield expectations for two or three years ahead are based. Thus the formula should be modified by known factors such as prices, costs, technological and ecological data which have influenced yields and which are expected to change the level of yields in the period of the insurance contract. The formula should be flexible enough to allow the insurer to reduce the normal yields when lower area yields are expected and to take the opposite course when higher yields are expected.²¹

If the second assumption listed—that the average deviation of yields from the mean is the same for all farms in an area—is

²⁰ If chief reliance is placed on a formula involving the projection of a trend it could be implied that the elasticity of expectations for yields is near unity. Actually it may be greater or less than unity and farmers may be aware of that fact. Hicks used the term "elasticity of expectations" as "The ratio of the proportional rise in expected prices (of a commodity) to the proportional rise in its current price." See J. R. Hicks, *Value and Capital* (Oxford University Press, 1939), p. 205. The term is used here in a similar sense, meaning that if a rise, or fall, in yields is expected to continue at the same rate the elasticity of expectations is unity. Cf. footnotes 14 and 21.

²¹ For an appraisal of how farmers may form their expectations in regard to yields see T. W. Schultz and O. H. Brownlee, "Two Trials to Determine Expectation Models Applicable to Agriculture," *Quarterly Journal of Economics*, LV (1942), 487-96. The insurer would be faced with the necessity of determining the production effects of changes in prices, costs, technological and ecological factors. Some margin of error could be allowed the insurer but in general the insurer would have to hold expectations for the area which are as precise as those held by farmers, if an adverse selectivity through time is to be avoided. Anything which adds to the degree of certainty in prices, such as a forward price program, would be an aid to the insurer in developing the normal yield.

replaced with the assumption that average deviations are not the same, it may be found that the farmers with relatively low yields will have a lower yield variation in bushels or pounds per acre than the farmers with relatively high yields. If this is the case, the farmers with high yields should insure for an acreage in excess of their seeded acreage in order to be completely protected, whereas farmers with relatively low yields could insure for less than their seeded acreage and still be completely protected. If it is found that the percentage variation in yields is more uniform than is the variation in terms of bushels or pounds per acre, then a reasonably equitable limit to put on the farmer's insurable acreage could be determined by setting an upper limit on the total acreage to be insured in an area and by allocating this acreage to farmers on the basis of relative production, yield times acreage, of the individual farms in the area. Such a method would allow the farmers in an area to be covered by insurance to the extent of relative output and it would prevent the insurer from offering insurance on a farm in excess of the farmer's normal insurable interest. In areas where average deviations of yields of individual farms do not differ to any marked degree, justice could be obtained by setting the limit on insurable acreage within about 90 percent to 110 percent of average seeded acreage on the farm.²²

Adaptation to several crops. A program of area-yield insurance could be applied to nearly all crops in an area by allowing a farmer to include several crops in his insurance program. For instance, a farmer could purchase 400 acres worth of insurance. This might cover his entire cropped acreage including a variety of crops. If wheat is the predominate crop in an area, the insurer may develop a schedule of premiums and indemnities based on records of wheat yields. An individual farmer who plants 100 acres of wheat, 50 acres of oats, 50 acres of barley, 50 acres of corn, 50 acres of sugar beets, and who has 50 acres of pasture and 50 acres of miscellaneous crops might insure his entire 400 acres by paying the premium required to insure a certain level of wheat yields in

²² The problem is (1) to prevent a farmer from insuring in excess of insurable interest, but (2) to allow a farmer to insure to almost the full extent of his insurable interest. In such an area a farmer with yields which are 110 percent of the area average might be allowed to insure up to 110 percent of his (base) seeded acreage, whereas a farmer whose yields were 90 percent of the area average might be allowed to insure for only 90 percent of his (base) seeded acreage. A special acreage allowance might be permitted for a high-risk farm in a low-risk area.

the area. His indemnity would depend on wheat yields in the area. His problem may be stated as follows: Will the general crop conditions which result in low yields for crops other than wheat also cause wheat yields to be low in the area? The general answer would be in the affirmative but the correlation may or may not be high. Among the small grains, for instance, a high correlation may be expected, but between wheat and corn, wheat and sugar beets, or wheat and pasture, the correlation probably would be lower. The value of this device would depend on the correlation existing between the area-yields of the crop used as a base and the yields of all crops which the farmer attempts to insure.

This example suggests two possibilities: (1) area-yield insurance might be based independently on two or more crops in an area; and (2) premiums and indemnities in an area might be based on a weighted average of the most important crops in the area.

Area yield insurance might be sold on the basis of the yields received for two or more crops in an area. In an area where acreage is divided among orchards, truck crops, dairying, and small grains, for example, the yield correlation among the crops might be so low that if insurance is based on wheat or grains alone, the indemnities received would not correspond with poor crops of fruit, vegetables, or feed.²³ In cases such as this an index of fruit yields might be calculated and area-yield insurance could be offered to fruit growers using the normal fruit yield as a base.²⁴ Likewise some index of yield might be developed for truck crops and area-yield insurance might be sold to truck farmers on the basis of this index. Area-yield insurance on the grains and feed crops grown could be offered on a similar basis. Insurance could be sold on each of several crops and a farmer could choose among them in any combination desired. The principle also could be extended to an index of yields for all of the major crops in an area and the weighted average yield

²³ It might be argued that when this condition is characteristic there is little need for crop insurance because (1) farmers' incomes would not be erratic because of yield variations, and (2) crop insurance would not improve resource utilization on the part of the firm. This argument would not hold in most cases, however, where the correlation is low but still significant.

²⁴ When yields are normal the index would stand at 100. When they are 90 percent of normal, the index would be 90. A farmer buying insurance could insure for yields of 50, 70, or 80 percent of normal, for instance. A range of premiums might be offered for insuring anywhere from 40 to 100 percent of normal. For discussion of a special problem which may be encountered in case of fruit, see Ralph R. Botts, "Development of 'Normal' Citrus Fruit Yields by Tree Ages for Use in a Yield Insurance Plan," this *Journal*, XXIII (1941), 867-72. The index for some crops such as tobacco might be on a yield-quality basis. See Wrather, *loc. cit.*

for any year could be expressed as a percentage of normal yield.²⁵ A farmer could insure for some percentage of normal yield and the insurer would calculate premiums and indemnities on the basis of yield experience in the area. A farmer would receive an indemnity whenever the index of yields is below the level for which he is insured.

Special problems. There are several specific risks such as hail or insect infestations which may affect an area at random. If the complete area were affected uniformly, the area-yield would be reduced and a farmer would be compensated accordingly for his crop loss attributable to the phenomenon. If only a portion of an area were affected or if the damage were not uniform over the area, a special problem exists. In this case, using hail as an example, the damage could be estimated and a specific indemnity would be paid for the particular loss.²⁶ The case for insect infestations and crop diseases appears more obscure because damaged areas may not be as clearly defined as is hail damage and insects or disease usually affect some crops more severely than others. Perhaps no special treatment can be developed at this stage for losses caused by insects or crop diseases.²⁷ The case for flooding is a special one which may best be handled by drawing area boundaries so that strips of land such as a slough or "bottomland," area which are most likely to flood would constitute an individual area.

²⁵ For discussion of the general problem of constructing a crop yield index for an area see E. J. Working, "Crop Yield Index Numbers," this *Journal*, XXII (1940), 701-13 and H. G. Hirsch, "Crop Yield Index Numbers," this *Journal*, XXV (1948), 583-98.

²⁶ The actuarial cost of the specific indemnity would be included in the original premium. In the case of hail, special adjusters would have to be employed to survey the damage over an area to determine whether any parts of an area should receive a special indemnity. If it was decided that they should, the case might be handled somewhat as follows. The regular area-yield indemnity, if any, could be calculated on the basis of the estimate of area-yield which would have existed in the absence of the hail storm and the indemnity for hail would be based on percent damage to the crop existing at the time of the storm.

The total indemnity may be calculated as follows:

Let

I = total indemnity,
 Y_i = insured yield,
 I_a = indemnity due from area-yield insurance, and
 h = percent hail damage.

Then $Y_i - I_a$ = balance of crop left after area-yield indemnity is calculated and

$$I = I_a + h(Y_i - I_a)$$

²⁷ This should be recognized as a case which may be settled according to the kind and extent of infestation or disease and which might be handled in a reasonably equitable manner through the use of special riders covering the specific risk involved to the extent that the risk is not covered by the regular area coverage.

General conclusion. The factors that appeared to work against the success of all-risk crop insurance will not lead to adverse selectivity within an area under area-yield insurance and will not endanger the success of the area-yield insurance program. Actuarial procedures can be adapted to prevent adverse selectivity and to enable the insurer to be indifferent, in an actuarial sense, to the facts (1) that yields trend upward on some farms and downward on others, (2) that yield deviations are not the same on all farms in an area, (3) that all farmers may not purchase insurance, and (4) that farmers may insure only part of their seeded acreage.

As long as the normal yield for an area can be determined accurately a system of yield probabilities may be developed for the area. The area yield probabilities may be used as the actuarial data and farmers can be protected against the occurrence of adverse crop conditions if areas are delineated so that there is a high positive correlation between crop conditions faced by the farmer and area yields. Where area yields are not an accurate indicator of these conditions, one of the other types of insurance may be more useful.

Parts of the United States where area-yield insurance should be most useful would appear to be regions such as the corn belt, the dry-farm and irrigated areas of the Great Plains, the Palouse Country of Washington, and other regions in which yields may vary uniformly in an area. It probably would not apply well to ranching areas or to cases in which crop yield variations are not uniform or consistent within an area.

Weather-Crop Insurance

Basic conditions. The basic assumptions for weather-crop insurance are. (1) that certain meteorological phenomena which depress crop yields can be defined and are measureable; and (2) that a schedule can be developed for a locality which will show the premium required to insure against an occurrence of these phenomena and the indemnity which will be associated with specific occurrences. The general formula for premiums and indemnities in any-locality would be constructed on the basis of an analysis of the relationship existing between certain weather phenomena and yields. Some of the weather phenomena which are known to be important in the determination of crop yields, such as rainfall and temperature, would be selected on the basis

of prior knowledge. Regression equations, based on simple or multiple correlations of yields and weather data, would be used to indicate the normal relationships and to indicate how yields might be expected to vary with variations in the phenomena selected. Insurance might be sold on the basis of calculated yield in an area, i.e. an indemnity would be paid whenever area calculated yield in any year was less than should occur with normal weather and the size of the indemnity would vary with the difference between the calculated yield and the "normal" yield.

Since the payment of indemnity to a farmer would be based on meteorological phenomena rather than on the yields of the individual farmer or of the area, the insurer would not be concerned in an actuarial sense about trends of yields, about which crops are insured, or about the consistency with which individual farmers insure. What is of significance in the analysis is the relationship existing between yields and the weather phenomena upon which indemnities are based. The value of the insurance for the farmer will depend on whether he will receive an indemnity when his yields are low because of adverse weather. Where a significantly high correlation between certain weather phenomena and yields is found, weather-crop insurance could be useful to farmers wishing to be protected against such adverse crop conditions.

The existence of high and significant correlations between crop yields and rainfall, soil moisture, and temperature has been established for several regions, particularly for the Great Plains region of the United States. Factors which might be included in a weather-crop insurance formula, therefore, are soil moisture at seeding time or preseasonal precipitation, seasonal precipitation, and growing season temperature or evaporation. The formula for calculating yields might include these three factors as variables or it might be merely a simple first degree regression equation using annual precipitation as the variable factor.²⁸

²⁸ For studies of weather-yield correlations see R. D. Bridgford and H. K. Hayes, "Correlation of Factors Affecting Yield of Hard Red Spring Wheat," *Journal of American Society of Agronomy*, XXIII (1931), 106-17; John S. Cole, *Correlations Between Annual Precipitation and the Yield of Spring Wheat in the Great Plains*; USDA Technical Bulletin 636, 1938, John S. Cole and O. R. Mathews, *Relation of the Depth to Which the Soil is Wet at Seeding Time to Yield of Spring Wheat on the Great Plains*; USDA Circular No. 563, 1940, G. W. Craddock and C. L. Forsling, *The Influence of Climate and Grazing on Spring-Fall Sheep Range in Southern Idaho*, USDA Technical Bulletin 600, 1938; Floyd E. Davis and J. E. Pallesen, "Effect of the Amount and Distribution of Rainfall and Evaporation During the Growing Season on Yields of Corn and Spring Wheat," *Journal of Agricultural Research*, LX

Test Cases. In several test cases on wheat grown in the Great Plains, use of a regression equation containing annual precipitation as the variable factor for estimating wheat yields would have made it possible for a farmer to make a greater reduction in the fluctuations in his annual net income through the use of weather-crop insurance than would have been possible through the use of all-risk crop insurance covering 75 percent of the base yield.²⁹ In one case which appears to be fairly typical a farmer using weather crop insurance would have failed to cover computed cash operating costs in only two of 28 years. If he had not used insurance he would have failed to cover computed cash operating costs in 15 out of the 28 years.³⁰ Further empirical investigation is needed to determine how typical such cases may be and to determine the extent of effectiveness for weather-crop insurance.

General conclusion. Weather-crop insurance would be adapted most easily to an area in which one or two weather factors, such as precipitation and temperature, are generally limiting and are

(1940), 1-23; A. L. Hallsted and E. H. Coles, "A Preliminary Report on the Relation Between Yield of Winter Wheat and Moisture in the Soil at Seeding Time," *ibid.*, XLI (1930), 469-73; A. L. Hallsted and O. R. Mathews, *Soil Moisture and Winter Wheat with Suggestions for Abandonment*, Kansas Agricultural Experiment Station Bulletin No. 273, 1936; J. W. Hopkins, "Weather and Wheat Yield in Western Canada, I. Influence of Rainfall and Temperature During the Growing Season on Plot Yields," *Canadian Journal of Research*, XII (1935), 306-34; Enoch W. Nelson, *The Influence of Precipitation and Grazing Upon Black Gramma Grass Range*, USDA Technical Bulletin 409, 1934; Ray F. Pengra, "Correlation Analysis of Precipitation and Crop Yield Data for the Sub-humid Areas of the Northern Great Plains," *Journal of the American Society of Agronomy*, XXXVIII (1946), 848-50; George A. Rogler and Howard J. Haas, "Range Production as Related to Soil Moisture and Precipitation on the Northern Great Plains," *ibid.*, XXXIX (1947), 378-89; V. P. Timoshenko, "Variability in Wheat Yields and Outputs," *Wheat Studies of the Food Research Institute*, XVIII (1942), 291-338 and *ibid.* XIX (1943), 151-202; L. R. Waldron "Yield and Protein Content of Hard Red Spring Wheat Under Conditions of High Temperature and Low Moisture," *Journal of Agricultural Research*, XLII (1933), 129-47; P. Patton, *The Relationship of Weather to Crops in the Plains Region of Montana*, Montana Agricultural Experiment Station Bulletin 206, 1927; H. L. Walster and P. A. Nystuen, *North Dakota Wheat Yields*, North Dakota Agricultural Experiment Station Bulletin 350, 1948. For weather and yield data, based on state averages, see Louis H. Bean, *Crop Yields and Weather*, USDA Miscellaneous Publication No. 471, 1942.

²⁹ This result was obtained using the assumption that premiums would be paid only in the years when estimated yield was above normal. Data are from John S. Cole, *op. cit.* They represent rainfall and experiment station yields for 14 stations in the Great Plains covering 272 crop years. This type of insurance could be made more effective in stabilizing income if the estimating equation is expanded to differentiate between preseasonal and seasonal precipitation and to include temperature or evaporation coefficients.

³⁰ Computed cash operating costs included cash outlays for all usual operations plus insurance premiums, normal depreciation allowances on machinery, and \$1,500 as the minimum family living allowance.

highly significant in the determination of crop yields. Semi-arid regions generally fit this description. In humid temperate areas the correlation between yields and weather factors may be less clearly defined and it may be relatively difficult to develop a reliable estimating equation for such areas. The magnitude of the coefficient of variability in yields may be less in these latter areas than in the semi-arid regions and the inaccuracies in the estimating equations would cause the errors in indemnity payments to be greater, compared with the premium level, than if the coefficient of variability of yields is large. In addition, weather-crop insurance may be of little value in case of crops where yields are strongly affected by risks such as insect infestations and certain crop diseases which may follow a year or two after a particular type of weather has been experienced.

Weather-crop insurance may be best adapted to grazing areas such as are found in semi-arid regions of the United States and under some conditions it may be useful in dry-farming areas.³¹ In such situations it may have important advantages in comparison with the other types of crop insurance. Since the actuarial basis of weather-crop insurance is weather data, actuarial tables would be unaffected by changing economic, technical or technological factors which may influence the general trend of yields. This is an advantage actuarially speaking, compared with area-yield insurance and all-risk crop insurance, because premiums would not have to be recomputed or revised when price changes or technological developments alter general yield prospects. Revisions would be made only when it became evident that the measurements of the weather phenomena had been inaccurate or unrepresentative.³² Thus once established, so that premiums and indemnities are actuarially correct, modifications in rates would be minor and infrequent.

Effects of the Actuarial Base on Resource Utilization

The use of crop insurance may have various effects on the

³¹ The term "dry-land farming" is used to typify a system of farming used in semi-arid regions of the United States where special moisture conservation practices are followed such as alternate cropping and fallowing, strip cropping, stubble mulching, and listing.

³² Ordinarily the premium-indemnity schedule would not be changed during short weather cycles, such as three- or four-year cycles, but changes would be made on basis of data covering longer periods of time. Cf. Timoshenko, *op. cit.*, XIX (1948), 294-97.

pattern and efficiency of resource utilization depending on the type of insurance used and on the relationship between yield expectations held by the farmer and his insured yield. It may be assumed, as a first approximation, that use of insurance would provide a basis for a farmer to measure the cost of the uncertainty inherent in the weather by presenting him with a specific premium-indemnity schedule. To the extent that it does this it should permit him to achieve a position of optimum resource utilization in a more consistent manner than he could achieve without insurance.³³ This first approximation must be modified, however, according to the assumptions that are made in respect to the three types of insurance.

All-risk crop insurance. The effect of all-risk crop insurance on resource utilization may depend on the relationship of a farmer's insured yield to his yield expectations in a given cost situation. Three distinct types of situations may be postulated as follows: (1) a situation in which yield expectations are normal with respect to the base yield; (2) a situation in which yield expectations are relatively poor, assumed to be about the level of insured yields; and (3) a situation in which yield expectations are very good, about 10 to 15 percent above the average yield of the base period. In each situation it is assumed that the farmer has some specific knowledge about the condition of his farm on which to base his expectations.

If yield expectations are about normal with respect to the base period, with crop insurance the farmer should be able to come closer to the point for optimum resource utilization than he could without insurance because the cost of uncertainty inherent in the weather will be defined and will be given an average value through payment of the premium. A fixed cost, the premium, will be substituted for an uncertain cost, the cost of yield variability.

If yield expectations are relatively poor, approximately at the level of the insured yield, for example, a pronounced change may take place in the plans for the firm. In this case the farmer may

³³ If certain unpaid costs which may arise through erosion, free public service, or family exploitation are neglected, and if the existing pattern of resource control or ownership is accepted as given, an optimum utilization of resources may be defined as a condition that exists when any small change in the production pattern leads to a combination of decrements and increments in output such that there is no system of exchanges whereby the increments will be accepted voluntarily as a compensation for the decrements.

restrict inputs to the level which is necessary to qualify for crop insurance.³⁴ By doing so he may eliminate any possibility of loss and in case weather conditions are more favorable than is normal a net return may be realized. The farmer would cover his costs if the yield is as expected. He would have a net gain equal to the harvesting expense if there is a complete crop failure and he would have a net return for management if weather conditions are more favorable than is normal. A farmer might prefer, therefore, that the crop would be a complete failure or that weather conditions would be unusually good.³⁵ In general the closer the expected yield approaches insured yield (from above), the greater would be the tendency to reduce inputs to the level necessary to qualify for crop insurance; and when expected yield is less than insured yield this tendency would be at a maximum.³⁶ If contracts are written containing the provisions which have been described—that the discounted value of the maximum insurance indemnity is equal to or greater than the cost of the qualifying inputs—crop prospects could not become bad enough to discourage seeding.

³⁴ The condition attached to the analysis is that the farmer must employ some minimum inputs in order to qualify for insurance. It is assumed that the cost of these inputs, plus cost of harvesting a relatively poor crop, plus the insurance premium, are equal to the maximum insurance indemnity.

³⁵ In some earlier years of the Federal crop insurance program a delay in the completion of contracts allowed some farmers to continue to plant and insure when crop failure was almost certain. See Clendenin, *op. cit.*, p. 250.

³⁶ This may help to explain why Congress, in an attempt to avoid losses which would be inherent in over-insuring, recently found it expedient to apply new restrictions on insured levels. The 1947 amendment to the Federal Crop Insurance Act read in part "... if 75 per centum of the average yield (on the insured farm) represents generally more protection than the investment in the crop in any area, taking into consideration recognized farming practices, the Board shall reduce such maximum percentage so as more nearly to reflect the investment in the crop in such area . . ." See 80th Congress, 1st Session, *Public Law 320* (S. 1926), p. 1, Sec. 508(a). The same provision was included in the crop insurance bill introduced in the Senate in 1949. Cf. 81st Congress, 1st Session, S. 898. For a discussion of the reasons for this amendment see 80th Congress, 1st Session, *Department of Agriculture Appropriation Bill for 1948, Hearings before the Subcommittee of the Committee on Appropriations, House of Representatives* (April 19, 1947), pp. 1696-1700. Insurance may be written to cover an average investment in the crop rather than a certain percentage of average yield. This type of insurance has been used on an experimental basis for corn and tobacco. See *Report of the Manager of the Federal Crop Insurance Corporation*, 1947, pp. 25, 30. This type of insurance has been sold on a lower coverage basis than the yield type because prices constitute an additional hazard. In 1947 the FCIC was limiting coverage on tobacco to 75 per cent of the average investment, or to about two-thirds of the coverage which could be secured through the yield type. By 1947 about 15 percent of the insured tobacco producers had selected the investment type of insurance. In the case of corn the coverage was equal to about one-half to two-thirds of the coverage provided by yield insurance on basis of 75 percent coverage of average yield.

If yield expectations are very good, 10 to 15 percent above average yields, crop insurance might not be used because of the reduced probability of receiving an indemnity. If crop insurance is used in such a setting, the pattern of resource utilization would be the same as when insurance is not used. With yield expectations normal or above, no distortion in resource utilization should occur.

Area-yield insurance. The effects of area-yield insurance on resource utilization would depend on the provisions of the contract as well as on the situation existing in respect to yield expectations. With yield expectations normal or above on the individual farm it can be demonstrated that inputs would be closer to the point of optimum resource utilization than they would be if insurance is not available. This is due to the fact that the reduction in yield uncertainty should minimize some of the limiting effects of capital rationing and should eliminate the necessity for attempts which may be made without insurance to minimize loss probabilities. With yield expectations relatively low, but not so low as to discourage seeding individual fields, a similar result may be expected. If yield expectations are so poor on the individual field that seeding does not appear to be profitable, the situation resulting would depend on the provisions of the insurance contract. If the insurance contract provides that the farmer must seed a certain acreage in order to qualify for crop insurance, this provision might force a farmer to seed some fields which he otherwise might handle in a different manner. If no such provision is in the contract, resource utilization would be determined by the crop prospect. If an objective of efficient resource utilization is held, therefore, no minimum seeded acreage on a particular farm, or perhaps only a rather small minimum acreage on a farm should be established as a condition for participation in insurance.³⁷

Weather-crop insurance. The effect of weather-crop insurance on resource utilization should be in the direction of an optimum resource utilization. The reason for this is that a farmer should find it most profitable to act in accordance with the yield probabilities existing at any particular time and yet he could arrange the capital

³⁷ The insurance carrier might be required to state that some minimum acreage should be seeded in an area as a condition for insurance participation in order to establish a base for indemnity payments. An alternative method for handling conditions which are so adverse that no crop is seeded would be to shift the base for indemnities from area-yield to weather, providing the actuarial data are available and comparable.

structure of the firm with greater certainty in regard to the income prospect because the income fluctuations caused by yield variations should be reduced or eliminated. At the same time the cost of the climatic hazard would be measured in terms of a specific premium schedule.

General Conclusions

Areas of Adaptation. The advantages and disadvantages of the three types of crop insurance are relative to the empirical situations confronted. In some low risk regions where the probability of indemnity does not change from year to year and in case of some crops where the current yield is not influenced greatly by a farmer's immediate action, all-risk crop insurance may be used without adverse selectivity or without adverse effects on the efficiency of resource utilization. The same type of insurance may be found less well adapted in other regions or among crops where the necessary conditions are not fulfilled. It may be inadequate and actuarially unworkable in a high risk region like the Great Plains. In such a region area-yield insurance and weather-crop insurance, according to the theory developed, should prove more satisfactory (1) because of the possibilities of providing a higher base for insured yields, (2) because the insurance programs can be made equitable in an actuarial sense and an adverse selectivity can be avoided, and (3) because both types should have a positive, rather than a negative, effect on the efficiency of resource utilization.

Suggested program. If these conclusions are correct the program for crop insurance in the United States should develop somewhat as follows: (1) Since all-risk crop insurance may be appropriate chiefly in low risk regions, or in regions where the first assumptions mentioned above are fulfilled, its use should be confined to such regions or situations. Empirical studies should be continued to determine the premium-indemnity schedules and the provisions which would be most appropriate for such regions or crops. (2) Since area-yield insurance may be most appropriate for the high risk crop regions such as the Great Plains, parts of the corn belt, the western cotton area, etc., empirical studies should be undertaken as a basis for instituting the program. These would involve the delineation of areas and the calculation of premium-indemnity schedules for each area.³⁸ (3) Since weather-yield insurance may be the only type

³⁸ Since 1947 an amendment to the Federal Crop Insurance Act has provided that the FCIC might insure or reinsure "... producers of agricultural commodities

appropriate for large areas of the western United States, especially the ranching areas, investigations should be continued as a basis for determining the specific relationship between weather phenomena, particularly precipitation, and range or forage yields. The weather phenomena then could be used as a basis for writing insurance on range or forage production.

In viewing the record of crop insurance in the United States most writers have counseled caution and have indicated that it may take years to develop a reasonably satisfactory program. For instance, the wheat crop insurance consulting committee appointed by the Board of Directors of the FCIC concluded in a report submitted in 1942 "... that the opportunity be afforded to accumulate the fullest data possible before the crop insurance program is ... extended."³⁹ Clendenin stated in 1942 that the goal of crop insurance is "eminently desirable, does not seem improbable of attainment, and justifies experiment with the single crop [wheat, *i.e.*, be restricted to wheat] until the attempt is either successful or proved definitely unlikely to succeed."⁴⁰ In 1947, the record of crop insurance was reviewed in detail in Congress, both on the floor of the House and Senate⁴¹ and before the House and Senate committees on agriculture.⁴² The House Agricultural Committee, in its report to accompany an amendment to the crop insurance act stated "... the committee believes it should be recognized that the development of a sound crop-insurance program covering even the major agricultural commodities on a nation-wide basis is a long-

under any plan or plans of insurance determined by the Board to be adapted to any such commodity ... for the purpose of determining the most practical plan, terms, and conditions of insurance ... " But the regular programs have been administered under the restrictions (1) that "... any insurance offered against loss in yield shall not cover in excess of 75 per centum of the recorded or appraised average yield of the commodity on the insured farm ..." and (2) that insurance shall not exceed the investment in the crop. See 80th Congress, 1st Session, *Public Law 320*, *loc. cit.* and 81st Congress, 1st Session, S. 898 These latter provisions in the law would have to be amended to permit the development of area-yield insurance or weather-crop insurance on a commercial basis.

³⁹ Herman L. Ekern, Robert J. Laubengayer, and Wilham G. Cochran, *Summary of Report of the Wheat Crop Consulting Committee on the Operations of the Federal Crop Insurance Corporation* (1942), p. 42

⁴⁰ J. C. Clendenin, *op. cit.*, p. 274.

⁴¹ See 80th Congress, 1st Session, *Congressional Record*, XCIII (March 31, July 3, July 9, July 25, and July 26, 1947), 3012-3015, 8440-8441, 8698-8699, 10296-10302, 10580-10581.

⁴² See 80th Congress, First Session, *Crop Insurance, Hearings before the Committee on Agriculture, House of Representatives* (March 20 and 21, 1947) and *Federal Crop Insurance, Hearings before the Committee on Agriculture and Forestry, United States Senate on S. 1326* (June 30, 1947).

time project that may well take years in its accomplishment. . . . The committee is convinced . . . that the best interests of farmers themselves will be most truly served if the Public Treasury is protected against excessive loss, by curtailment of the insurance program during its development period to the smallest scale consistent with effective experimentation, and expanding it later only when experience has indicated that a sound insurance plan has been worked out. . . . ”⁴³

While the above statements are well founded in terms of general experience, the conclusion seems inescapable that the chief reason for failures is that programs have been based on a faulty conception of the actuarial problems involved. If the most appropriate structure for actuarial purposes is used, crop insurance programs might be developed on a nation-wide scale more rapidly than has been usually indicated. This would involve (1) placing greater emphasis on determining the most suitable actuarial base for the particular region and crop, (2) marshalling the data necessary for use with this base, and (3) developing the administrative organizations and techniques which may be most appropriate.

⁴³ See *Report of the Manager of the Federal Crop Insurance Corporation*, 1947, p. 4.

THE FIELD OF AGRICULTURAL MARKETING RESEARCH: OBJECTIVES, DEFINITION, CONTENT, CRITERIA

GEOFFREY SHEPHERD
Iowa State College

THE OBJECTIVES, definition, content, and criteria for the field of agricultural marketing are all related. Let us see if we can set them down, separately, but in proper relation to one another.

Objectives of Agricultural Marketing Research

What is the over-all objective of research in agricultural marketing?

Some believe that the over-all objective is to increase the consumption of farm products.¹ Many believe that the objective is to maximize farmers' net returns.² Title II of the Research and Marketing Act of 1946 declares that "a sound, efficient, and privately operated system for distributing and marketing agricultural products is essential to a prosperous agriculture and is indispensable to the maintenance of full employment and to the welfare, prosperity, and health of the Nation." This apparently is the legislators' objective in providing for marketing research. Economists are likely to hold the view that the objective of marketing research is merely a part of the general economic objective of allocating scarce resources so as to maximize the output of goods and services.³ Others may have still other goals.

Let us consider these different over-all objectives in turn.

Increasing the consumption of farm products is an acceptable objective, from a national point of view, only if nutritional and clothing needs are not already being met. If nutritional and clothing needs are being met, it is difficult to see, from a national point of view, why there is any more intrinsic merit in increasing the consumption of farm products than in increasing the consumption of other products.

To take a concrete case: Nutritional studies show that all income

¹ This objective, for example, was written into the basic project statement of the North Central Regional committee on dairy marketing research in 1947.

² "Report of the New York Milkshed Price Committee," Feb. 1949, p. 5.

³ This objective is stressed by R. G. Bressler in his article, "Agricultural Marketing Research" this *Journal*, XXXI, No. 1, Part 2, Feb. 1949, pp. 553-562.

groups consume substantially less milk than they need for adequate nutrition.⁴ Research directed toward expanding the consumption of milk therefore would benefit the nation as a whole. Nutritional studies also show that all income groups consume substantially more butter and other fats than they need, nutritionally. Research directed toward expanding the consumption of butter and other fats could not well be justified on the same grounds as for milk.

Maximizing farmers' net returns. This objective is implicit if not explicit in much agricultural marketing research.

So far as farmers' net returns can be maximized by reducing marketing costs, the nation would benefit as well as the farmers concerned. But net returns also can be maximized by monopolistic action to raise prices. Such monopolistic action would be inimical to national welfare, and farmers object to it when it is practiced by other groups. It can hardly be included uncritically as a legitimate objective for agricultural marketing research.

A similar objective is sometimes expressed in different words—to *increase farm incomes*. Before that objective could be accepted, the case would have to be made that farmers' incomes needed increasing more than other peoples' incomes.⁵ This case is relatively easy to establish during depression, when farm incomes decline more than the incomes of most other groups. It is less easy to establish during booms, when farm incomes rise more than the incomes of most other groups.⁶ In any case, the particular method of raising farm incomes by marketing research would have to be examined. The citrus growers over the past few decades have done a remarkably good job of marketing their product, and research may have been a big factor in getting the job done. Yet the prices of citrus fruits stand now at almost the lowest percentage of parity on the whole list of farm products—11 percent in March 1948, and even after the big freeze last Fall, only 31 percent in March 1949. Good marketing alone was not able to ensure high farm income.⁷

⁴ Willard W. Cochrane, *High-Level Food Consumption in the United States*, BAE, USDA, Misc. Pub. No. 581, December 1945, p. 10.

⁵ The arguments on this point go on and on. For the most recent discussion, see Carl Kaysen and James H. Lorie, "A note on Professor Schultz's Analysis of the Long Run Agricultural Problem," *Review of Economics and Statistics* XXX: 286-295, Nov. 1948. Schultz, T. W. "A comment," this *Journal* XXX: 295-296 Nov. 1948. Carl Kaysen and James H. Lorie. "A rejoinder," this *Journal* XXX: 296-297, Nov. 1948.

⁶ 1949 *Agricultural Outlook Charts*, USDA, BAE, Washington, D. C., Oct. 1948, p. 7.

⁷ This paragraph barely scratches the surface of the whole problem whether net

The suggestion has been made in some quarters that agricultural economists should seek to increase farm income in any case—because “the farmer’s the fellow you’re working for”—regardless of the national welfare.

This is clearly a misconception. An agricultural economist on the payroll of a farm commodity pressure group or general farm organization may have that limited objective, but his views would require examination to make sure they were not biased by his connections. The agricultural economist at a college or university is in a different situation. He is a scientist. He is not “working for the farmer” or any other special group. He is working for everybody, seeking for objective impartial truth, just as an atomic research man is not working for the aluminum interests or the uranium interests, but for society as a whole.

It seems clear that the over-all objective of research in agricultural marketing, at any scientific institution worthy of the name, must be in line with the objectives of all scientific institutions—the maximum satisfaction of consumers’ demands—through the maintenance or development of pricing systems that accurately reflect those demands and allocate resources to their maximum satisfaction, and through the reduction of marketing costs.

Scope of the Field

The field of agricultural marketing can be defined either narrowly or broadly.

A narrow definition of the field is frequently used. It restricts the field of marketing to the job of getting the product from the harvest field to the consumer’s table. This appears to be the definition adopted in the Research and Marketing Act of 1946, although no explicit definition as such is given in the Act.

This narrower definition is suited to the purposes of the Act, which are to direct research into a part of the field that previously has been neglected. But it does not provide adequate coverage of the field as a whole. Put in everyday language, the narrower definition reflects this view: “Here’s the stuff. We’ve produced it; now you sell it as best you can. And see if you can’t develop some new uses for it, to help us get rid of it.”

farm income per capita can be raised without the aid of additional measures to facilitate the movement of the half million a year of young farmers growing up in excess of the number needed in agriculture. I have attempted to deal with this problem in Chapters 29 and 30 of my *Agricultural Price Policy*.

The shortcomings of this view are evident. Many marketing problems arise because the right variety of crop was not planted in the first place. Many other marketing problems arise because the right quantity was not produced. To begin with the harvested crop on the ground is to begin too late, after much of the marketing problem is already past solution.

In order to deal with marketing problems adequately, therefore, we need to define the field broadly enough to encompass all the forces that create the problems. We need to include studies of consumer demand (its relation to income, its elasticity, changes, etc.) price policies, and so forth.³

Which End of the Field to Start With?

We also need to look at the field of agricultural marketing from the proper end.

That is to say, we should not start with what farmers have produced; we should start with what consumers want. We need to start with consumers' demands for food and clothing, and see how well producers can meet them. Production without regard to consumers' wants obviously is poor business for producers as well as for consumers and the nation as a whole. Adam Smith may be out of date on some things, but he was correct and still is correct in his observation that consumption is the aim and end of all production. Any producer who does not start with what the market wants and then try to produce it is asking to go broke.

If we were living in a purely competitive economic environment, consumers' demands would be a sufficient starting point. But our environment is not economic only; we live in a partly welfare state, as well as an economic one. We take into account consumers' *needs*, as well as their *demands*. Some groups at some times do not earn enough to back up their demand for food and clothing with purchasing power (in the economic sense, of course, demand does

³ I believe that this is substantially the same thing that L. J. Norton had in mind when he outlined as the first problem in marketing research, *The Market*. . . . "This term is used to mean the quantitative and price aspects of an economy's sales of a particular good." Norton then defined the first subdivision of this problem as "price-quantity relationships, income effects, distribution-of-income effects, general price level effect, competitive relationships, secular tendencies in relative demands, etc." (this *Journal*, XXXI . 1, May, 1949, pp. 350-351).

Norton's article was drawn to my attention by the Editor of this *Journal* after I sent my manuscript in to him. It appears to me that we have arrived independently at much the same conclusion, that the field of marketing needs to be defined broadly to include the study of consumer demand.

not exist unless it is backed up by purchasing power). When this happens, we do not let those people starve and freeze. In one way or another, we give them purchasing power to buy enough food and clothing to provide for their minimum needs. The determination of these needs is a job for nutritionists and others in the sciences involved; but figuring out how to provide for those needs, and estimating how much this provision will add to the total demand, surely is part of the field of agricultural marketing research.

Extent of the Field

We may agree that we should begin with consumer demand. But that is only a beginning.

Where we go from there, to define the field of marketing, can be shown best by a diagram such as Figure 1.

FIG 1

The upper negatively sloping curve DD represents consumer demand for farm products at retail. It has an elasticity of -0.4 , the figure estimated by Cochrane.⁹ The lower sloping line D_1D_1 represents the demand curve for farm products at the farm. It lies below the upper curve DD by the amount of the marketing costs.

⁹ Willard W Cochrane, *Farm Price Gyration—An Aggregative Hypothesis*, this *Journal*, XXIX, No. 2, May, 1947.

The long-run supply curve for farm products is represented by the positively sloping¹⁰ line SS. It intersects the demand curve for farm products at the farm, D_1D_1 . The vertical line above the point of intersection cuts the demand curve for farm products at retail.

In terms of this diagram, the field of marketing may be defined as everything above the line D_1D_1 .

In similar terms, everything below the line SS is farm management or production.¹¹

Content of the Field

As defined above, the field of agricultural marketing includes three major parts.

The first part deals with the position, elasticity, curvature, etc., of the demand curve for farm products at retail, the relation of the curve to consumer income, and so forth. It includes such questions as whether attempts should be made to shift the curve up or down, or to keep it from shifting up or down.

The second part of the field of agricultural marketing deals with prices. Consumers' demands are the guides to producers as they lay their production and marketing plans, and one of the best media for transmitting these demands to producers is the system of prices. The accuracy and clarity of prices as lenses refracting consumer demands therefore is an essential area of study in the field of agricultural marketing. Private and public agricultural price policy are both included here.

The field of agricultural marketing obviously also includes the area of costs and profits lying between the two sloping curves. The field is sketched above in terms of farm products as a group; it includes also the different products taken separately, and relations among the different products.

The three major parts of the field of agricultural marketing can thus be described in summary terms.

¹⁰ There is evidence that the short-run supply curve for farm products is practically vertical. The supply curves for individual farm products are more elastic. (Cochrane, *op cit.*)

¹¹ A question may be raised. What about the area to the right of the intersection of D_1D_1 and SS, above D_1D_1 and below SS? Is it marketing, or production?

The answer is that really there is no such area. The demand and supply curves do not intersect, strictly speaking. They lie on different planes, the one representing the responses of consumers, and the other representing (with appropriate lags) the responses of producers.

1. Consumer demand for farm products—elasticity, and changes.
2. The prices that refract these demands more or less perfectly to producers.
3. The costs of marketing intervening between producers and consumers.

Specific Objectives

At the end of the first section of this paper, after the general objective of agricultural marketing research was set forth, the statement was made that the specific objectives could best be drawn up after the scope and content of the field was outlined. We are now in a position to draw up these specific objectives.

The belief is often expressed that the objective of agricultural marketing research is to reduce the costs of marketing. Farm management research, for example, can promote the maximum satisfaction of consumers' demands if its objective is to reduce the costs of production. Similarly, marketing research can promote the maximum satisfaction of consumers' demands if its objective is to reduce the costs of marketing.

Reducing the costs of marketing clearly is one major and essential objective in marketing research. But it is not the only one; it is in fact only the third of three related objectives under the general objective of maximum satisfaction of consumers' wants.

In the light of the three parts of the field shown above, the first objective clearly is to determine consumers' demands. The second objective then is to ensure that the marketing system accurately reflects those demands clear back to the producer, so that he can produce accordingly. Reducing the cost of getting those goods to the consumer then is the third of the three related objectives.

Let us examine these specific objectives a little more fully.

To determine consumer demands:

The study of consumer demands falls naturally into two parts, one dealing with the demand for existing products, and the other with the potential demand for new products.

The consumer demand for existing products is objectively represented in retail prices and quantities sold. The job in this case is to get the data, analyse them, and see what they mean in terms of relative costs. The quantities of a particular grade or package that can be sold at price differentials sufficient to cover the cost differ-

entials for packaging, or of producing the product in the first place, may be too small to warrant selling that grade; or they may be so large as to warrant increased production of it.

The potential demand for new products is more difficult to measure.

In some cases the "new" product may be a familiar one, already on the market, the "newness" consisting only of its being made from farm products. An illustration of this is the manufacture of industrial alcohol from domestic farm products, where previously it has been made chiefly from molasses (mostly imported) and derivatives of petroleum. The job here is to estimate the costs of the new source, or of the new process, and see how it stacks up in the competition with existing processes and products.

In other cases, the new product may be really new, or at least not generally familiar. Avocado pears used to be a good example of this. Sweet corn, husked and wrapped in cellophane, is a more recent example of a new package (rather than product). In these cases, a controlled experiment, based on sales at different prices in a regular retail store is a good way to measure the consumer demand.

To ensure that the marketing system accurately reflects consumer demands:

The second objective is to ensure that the marketing system accurately reflects consumer wants. In war time, consumer needs are given greater recognition than in peace time, and a whole complex system of government rationing and price controls is usually employed to do the job. This method was continued for some time after the war in many European countries. But in the United States we got back to open market prices as reflectors of consumer demands as quickly as we could.

In peacetime, at least in the United States, this second objective is primarily a market price objective. The criterion or standard of reference here is the concept of the perfect market. This is analogous to the physicists' perfect vacuum, or frictionless motion—never attainable in actual life, but nevertheless an essential standard of reference.

The distinguishing feature of a perfect market is that a uniform price prevails, with proper allowances for differences in place, time and form. Most markets (groups of traders) are scattered

over a considerable area of space. The "uniform" price in a perfect market therefore is uniform plus or minus transportation and handling charges from one geographical point to another. This traditional criterion of uniformity in *space* is supplemented by a corresponding criterion of uniformity in *time*, plus or minus storage and handling costs from one period of time to another while basic supply and demand remain unchanged. Finally, a third criterion of market perfection is the uniformity of prices for different grades of a product—that is, uniformity in *form*, plus or minus conversion (processing) or production costs from or between different grades. These three criteria correspond with the orthodox division of utilities, in economic theory, into space, time, and form utilities.

In a perfect market, therefore, prices at any one time are uniform over geographical areas, plus or minus the cost of getting supplies from surplus to deficit areas. The price of fresh pork loins, for example, in New York City would be the same as the price in Chicago plus transportation and handling charges from the one city to the other.

Prices in a perfect market also would be uniform at any one point over periods of time, plus or minus the costs of storing from one period to another (or the costs of producing at different times). The price of cotton would rise after harvest by an amount equal to the costs of storage.

Finally, the prices for different grades of a product in a perfect market at any one point of time would be uniform plus or minus the costs of converting the product from one grade or form to another, or the relative costs of producing the different grades. The price of choice steers would exceed the price of good steers by the difference between the costs of producing the one and the other.

The three-fold criterion of the perfect market can be summarized in brief tabular form as shown in Table I on page 453.

This criterion, the perfect market, in which differences in prices equal differences in costs, is merely a specialized part of the criterion that is generally accepted for the whole field of economics—the equivalence of marginal revenues to marginal costs. This maximizes production from a given set of resources. In a perfectly competitive market (with horizontal demand curves for the products of individual producers) the equivalence of marginal revenues and costs leads to an equivalence of average revenues and costs.

TABLE I. FUNDAMENTAL ELEMENTS OF THE CRITERION OF THE PERFECT MARKET

	Time	Place	Form
(1) Prices	Price movements over long, medium and short periods of time.	Price differentials between different places.	Price differentials between different grades.
(2) Costs	a. Costs of production at different times and b. Costs of storage from one time to another.	a. Costs of production in different places and b. Costs of transportation from one place to another.	a. Costs of production of different grades and b. Costs of processing the same product into different grades.

This concept of the perfect market is useful also as a framework for classifying marketing research projects and organizing the content of marketing books,¹² as well as for appraising individual marketing problems.¹³

Max Brunk, however, disputes the usefulness of the concept, in the following words:

"... for a number of years now, marketing researchers have been obtaining facts based on well formulated hypotheses which serve to modify some of the basic assumptions behind the ideal market concept. If we must continue to ignore these modifications and return to a static ideal market concept for a framework within which to fit our studies, evaluate past work and plan future work, we can hope to make little progress. This does not deny the importance of competitive economic theory in the formulation and constant improvement of basic concepts, but it does seem to censure researchers for not having used theory in the development of concept modifications in the light of facts which have been thus far developed. Science progresses only to the extent that new hypotheses are developed from the testing of old hypotheses. We cannot expect to make much progress by continually basing our research on concepts which fail to grow. Needless to say, our marketing system today bears little semblance to that envisioned by classical economists."¹⁴

Bressler evidently anticipated criticism on the point, in the full paragraph on page 555 of his article. Apparently, however, this did not satisfy his first discussant.

Brunk makes one constructive suggestion. He says: "As for the need of a benchmark by which to measure accomplishment, it appears to me that the existing market supplies a more meaningful

¹² See Chapter 3 of my original *Agricultural Price Analysis*, Iowa State College Press, 1941, and the table of contents of my *Marketing Farm Products*, 1947.

¹³ R. G. Bressler uses it well for both purposes in his *Agricultural Marketing Research*, this *Journal*, XXXI, No. 1, Part 2, Feb., 1949, pp. 553-562.

¹⁴ Max E. Brunk, *Discussion* (of Bressler's paper), this *Journal*, XXXI, No. 1, Part 2, Feb., 1949, p. 563.

base. Such a base, of course, fails to indice maximum possible achievement."¹⁵

Brunk's point needs discussion. How does "the existing market" supply any kind of a base, still less "a more meaningful base," than the ideal or perfect market? How can you tell by looking at the existing market whether any improvement in its prices is desirable or can be made? How do you know what "improvement" is? In which direction, if any, should prices be changed? And how can you tell whether they would be any "better" than before? What does "better" mean?

To be specific, how would you know whether the existing short-time variations in futures market prices were wider or more frequent than necessary? What is necessary? How would you know whether price differentials between Chicago and New York were too wide or too narrow?

Yet I am not disposed to throw Brunk's criticism out entirely. I may well be that in some cases the open competitive market is an obsolete criterion of market performance. In some cases, the economies of scale may be so great that one large corporation can make or market a product at lower cost than a large number of atomistically competing small units, even though the large corporation exercises some monopoly powers. I would merely say that each situation needs to be examined with reference to this point and the appropriate criterion used for each case.

To reduce marketing costs:

Costs also fall under the three heads of place, time and form. There are costs of transportation from one *place* to another, costs of storage from one *time* to another, and costs of conversion from one *form* to another. These costs are the bases for the place, time and form differentials in prices discussed above.

These costs are involved at various points along the distributive system. Thomsen urges that more attention be given to the costs at the retail end of the chain, for those costs take the largest share of the consumer's dollar.¹⁶ I think that probably he is right in this point. The size of the part of the consumer's dollar that goes to a specific function establishes a presumption that research in that

¹⁵ Max E. Brunk, *Discussion*, this *Journal*, XXXI, No. 1, Part 2, Feb. 1949, p. 562.

¹⁶ F. L. Thomsen, *A Critical Examination of Marketing Research*, this *Journal*, XXVII: 4, Nov. 1945, pp. 947-902.

area will yield greater results than research where there is less room for reductions to be made. But the size of the share of the consumer's dollar is not a sufficient criterion alone for determining the place where research projects are most likely to be fruitful. A prospector strikes it rich, not by working the biggest mountain, where traces of gold may be scattered all about, but by working the mountain, regardless of size, where gold is concentrated in veins. A marketing research project may be able to show how a 20 percent reduction can be made in a small-cost function, more easily than a two percent reduction in a large-cost function, and thus end up with a greater reduction in cents. And that is what counts.

Determining where the veins are is as difficult for a research man as for a prospector, and perhaps luck is as much involved in the one case as in the other. The development of criteria for choosing profitable areas for research stands as a challenge to research men and administrators both; we need to work out scientific objective methods analogous to the geophysical methods that have raised petroleum prospecting from a wildcatting proposition to a more scientific level.

LAND REFORM AND THE TRANSFORMATION OF AGRICULTURE IN HUNGARY

ALEXANDER ECKSTEIN*

HUNGARY remained one of the last strongholds of feudal or semi-feudal forms of tenure in Europe up to 1945. Less than one percent of the farm-holders owned almost half of the agricultural land. Close to one-third of the agricultural land was in holdings of over 1,000 cadastral yokes (approximately 575 hectares).¹

A powerful landed aristocracy based on large latifundia survived the defeat of World War I and the consequent wave of agrarian upheavals sweeping Eastern Europe. It took another defeat in World War II and a revolution to bring about a subdivision of these large estates, through a series of measures known as the "land reform."

Peculiarities of the country's historical, political, and economic development tended to keep feudalism dominant longer than in other parts of Europe. The resulting continuing inequities in land distribution aggravated the effects of acute population pressure upon arable land resources in a highly specialized and extensive type of agriculture.

The combined momentum of a landless agricultural proletariat, a poverty-stricken peasantry, and an underdeveloped agricultural economy resulted in a situation where some form of change became inevitable. When it came, the change involved not only a redirection of land policy but also significant transformations in the country's agriculture. These transformations and their effect upon farm organization, agricultural labor and employment are analyzed in this paper

Land Reform of the 'Twenties

The basic land tenure pattern in Hungary was fairly definitely fixed by the time of the peasant liberation of 1848. Even after the peasants acquired ownership of the lands on which they worked, a large proportion of the country's agricultural area remained in

* On leave from FAO; currently a fellow of the Social Science Research Council. The opinions expressed do not necessarily reflect the views of either of these organizations.

¹ Kerek, Michael; Agricultural Land Reform in Hungary, *Hungarian Quarterly*, Vol. 6, No. 3, 1940.

estates of over 1,000 cadastral yokes.² The agricultural economy continued to be characterized by a very large number of small farms and a comparatively small number of large estates.

As time went on the situation of the small peasantry deteriorated. Prevailing inheritance practices led to fragmentation of holdings, and overseas grain price competition forced many peasants into heavy debt. A considerable number lost their holdings and joined the ranks of those who even in 1848 were left landless. The potent land hunger of this agricultural proletariat furnished the strongest pressure for post World War I reform.

The short-lived revolutionary regimes of 1918 and 1919 initiated steps to solve the land problem. These beginnings could not be ignored even by the victorious government. Some measure of land redistribution was instituted, both to satisfy the pressing demand of the peasantry and to subdue its revolutionary force.

Altogether about one million cadastral yokes were appropriated by the State, representing about six percent of the total area in farms, and a higher proportion of cultivated land. Out of this total, slightly over 705 thousand cadastral yokes were distributed to almost 390 thousand individuals.³ The average parcel was 1.8 cadastral yokes (2.56 acres).

The maximum allotment that could be obtained by the landless workers—the largest category of claimants—was three cadastral yokes. As a result, a very large number of uneconomical dwarf holdings were created. About 185 thousand landless farm workers and 113 thousand dwarf and small holders were the principal beneficiaries of reform. Besides obtaining land, they derived indirect benefits through the enlargement of community pastures by about 80 thousand cadastral yokes.

By 1931 redistribution of land was just about completed, so results of the 1935 Census returns can be taken as indicative of the effect of the reform.

The most striking feature of this table is that 306 holdings encompassed 11.8 percent of the land area, while over 664 thousand holdings embraced only ten percent of the land. Less than one-tenth of one percent of the landowners, with holdings of over 1,000

² No statistics of land distribution are available for this period, but it has been estimated that over one-third of the land was in estates of over 1,000 cadastral yokes.

cadastral yokes, possessed 24.5 percent of the land. On the other hand, 45.9 percent of the farmers with holdings of one to ten cadastral yokes, owned only 19.3 percent of the land.

The picture is considerably distorted by the inclusion of holdings with less than one cadastral yoke (1.421 acres). A number of these holdings, located near cities, were owned by small craftsmen and industrial workers who operated them for supplementary income. However, the majority of these plots were owned by people who earned their livelihood in agriculture, principally as farm laborers.

Comparing the 1935 distribution with that at the time of the last pre-war Census, in 1895, it becomes apparent that there was some shift in farm size distribution in favor of the smaller farms. The proportion of the area in farms of under five cadastral yokes increased by substantially more than the number. Also, the relative decrease in the area of farms of five to 100 cadastral yokes was much smaller than the proportionate decline in number. At the same time, the area in estates of over 1,000 cadastral yokes decreased from about 32 percent to 24 percent.

Effect of Reform Upon Land Tenure

The post-World War I land measures did not materially affect tenure conditions and relationships in Hungary's agriculture. Strip farming continued a basic feature of the country's agricultural pattern. On the other hand, close to 25 thousand entailed holdings

covering an area of 3.6 million cadastral yokes were still intact in 1935. Farm tenancy, in the sense of outright tenant operation, was not common, but leasing of land by owner-operators in order to enlarge their operating unit was spreading.

Widespread practice of strip farming aggravated problems on small holdings which were not economical in terms of size in the first place. In 1935, half the farms were composed of several plots, many times widely scattered. In fact these one million holdings were composed of 6.4 million plots—an average of six plots per farm. The average size of a strip was one hectare with many plots much smaller. It is evident that this type of farming permits only a very low level of productive efficiency, particularly in an extensive agriculture.

Strip farming is not peculiar to Hungary, but is fairly common in many parts of Europe. It is a product of the interaction of rapid farm population growth, limited non-agricultural employment opportunities, and inheritance practices which provide for equal division of land among all heirs. In many cases several separated parcels of land were allotted to heirs, in order to insure equity among them in regard to quality of land obtained. To the extent that this practice has been applied in the case of land distribution after the 1920 reform, it has tended to accentuate fragmentation of holdings

Effect of Reform on Agricultural Labor and Employment

Landlessness of the agricultural proletariat, it will be remembered, furnished the most potent drive for the land redistribution of the 'twenties. However, even on completion of the reform, the number of farm laborers who acquired land was relatively small, so this basic problem remained unsolved.

In 1930, out of two million actively engaged in agriculture, there still were 769 thousand landless. Their number dropped somewhat, to 746 thousand by 1941, as a result of some further land settlement and movement to cities.⁴ But the old problems of seasonal employment, unemployment and underemployment remained the plague of farm labor throughout the inter-war period.

Defining agricultural unemployment is at best complex, particu-

⁴ Thirring, Lajos; *Foglalkozási Eltolódások 1930 és 1941 Kozt* (Changes in occupational distribution between 1930 and 1941)—Magyar Statisztikai Szemle, Jan.-Feb. 1947, p. 3.

larly under conditions such as prevail in Hungary. The dominant characteristic of Hungarian agriculture is a marked concentration upon grain production, with over 70 percent of the country's cultivated area in cereals. The average annual labor requirements of grain culture are low; but there is a very high peak load at harvesting, and secondary loads at planting and cultivating time. This seasonality in employment was greatly accentuated by the dearth of farm machinery and the prevalence of large holdings completely dependent upon outside labor for their farm operations. This type of farm organization demands a labor force adequate to meet peak seasonal requirements even though it is unemployed or very inefficiently utilized during the rest of the year. Off-season employment opportunities for farm labor were extremely limited due to the relatively low level of industrial development and activity. This additional factor tended to depress farm wages and real annual earnings. Thus the cost of labor was partly shifted by the large holdings onto society.

Inasmuch as inefficient labor utilization is firmly rooted in the prevailing pattern of farm organization, it not only affects landless farm labor, but the self-employed smallholding peasantry as well. In the latter case, of course, periods of full employment, partial employment and unemployment are not clearly distinguishable over the year, but they nevertheless exist. The large majority of small holdings with the prevailing type of agriculture are unable to utilize fully the labor of the peasant and his family all year round.

This under-utilization of the agricultural labor force in under-developed economies may be termed "disguised unemployment." It applies to a condition in which the marginal productivity of labor over a certain range is close to zero. This does not imply that labor could be withdrawn from agriculture without decreasing farm production, unless this withdrawal of labor is accompanied by improvement in technology, changes in farm organization, or improved agricultural skills and practices.⁵

A number of empirical investigations of labor requirements in Hungary's agriculture⁶ seem to throw some light upon this problem.

⁵ Under some types of conditions where the marginal productivity of farm labor over a certain range may be at zero or possibly even negative, part of the labor force could be withdrawn from agriculture, leaving technology, farm organization, and practices unchanged, without affecting farm production.

⁶ Series of studies by Matolcs, Nagy, Kovacs, Szeibert and others conducted during 1930-39

These studies show that in the early thirties there were about 1.3 million men, 580 thousand women, and 158 thousand children in the agricultural labor force. These were capable of supplying an estimated 471 million man days of labor as compared to an estimated total labor requirement of 360 million man days. This indicates a waste of 24 percent of the available labor-time supply. Actually 20 to 30 percent of the agricultural labor force was employed for less than 200 days during the year.

The 1945 Reform and Its Results

The land reform of the 'twenties was not designed to solve effectively the problems of land distribution, agricultural labor and unemployment. Neither did it further the establishment and extension of middle-sized efficient family farm units. On the contrary, it led to the creation of a large number of dwarf holdings, insufficient in size to provide an adequate income to the farmer and his family. He was still forced to seek labor on the estates, which had fewer work opportunities to offer because of their somewhat reduced size.

Thus essentially the same economic and social problems and conflicts that harassed the agricultural economy of the country prior to World War I were still present prior to World War II. They helped propel the revolutionary forces determined to abolish the landed aristocracy once and for all.

On March 18, 1945, the provisional government issued a decree concerning the *Termination of the System of Large Estates and Redistribution of Land to the Peasantry*, which provides:⁷

Lands and properties of traitors, fascists, nazis, war criminals, etc., are to be confiscated outright, without regard to size of farm. On the other hand, owners of estates of above 1,000 cadastral yokes forfeit the right to retain land, but are compensated for their holdings. Farms of 100 to 1,000 cadastral yokes may retain 100 (only 50 in the case of farms located within a radius of 30 kilometers from Budapest) with the rest to be redeemed. Farmers who work the land themselves may keep up to 200 cadastral yokes, but distinguished soldiers of resistance and liberation may retain up to 300 yokes. In the case of vineyards and orchards, the maximum holding is 20 cadastral yokes with the proviso that such land may not be used for other types of production than heretofore. Community

⁷ Neplap, Debrecen, March 18, 1945.

pastures, agricultural research stations, government model farms and some others are exempt from all these provisions.

Forests receive separate treatment. All forests above 10 cadastral yokes are nationalized; those of 10 to 100 yokes become community, village or municipal property, while individuals may retain up to 10 yokes.

Holdings may keep as much farm equipment, livestock, buildings and other implements as are needed to work the remaining portion of the farm. Agricultural cooperatives absorb the balance of the equipment, some of which is retained for cooperative use while some is distributed to the farmers.

All landless farm servants and laborers, dwarfholders and small farmers are entitled to claim land. The maximum amount that may be allotted to anyone is 15 cadastral yokes of arable land and pasture, in addition to three yokes of garden and vineyard. In some exceptional cases, this may be increased to 25 plus five respectively. The new properties may not be mortgaged or subject to forced sale for ten years, except for taxes and the down payment on the land purchase price.

The new landowners are obligated to make a down payment of 10 percent of the purchase price, the latter to be fixed at twenty times the value of the cadastral net revenue. Down payments may be postponed for three years, with the remaining portion to be paid in ten to twenty annual installments. Estimates of the total cost to the peasants of the newly acquired lands have been set at 883 million forints (approximately 75.5 million dollars in U. S. currency).

On the basis of the law of 1945, about 43 thousand farms with

TABLE II. EXPROPRIATED AREA BY TYPE OF LAND USE

close to 540 thousand cadastral yokes were confiscated outright and about 8,500 holdings, with 4.8 million yokes, redeemed. The total land made available for distribution was 5.6 million cadastral yokes which represents one-third of the country's land area.

These data indicate that over 3.2 million cadastral yokes have been distributed to individual claimants. This represents 58 percent of the total expropriated area. However, if forest land is excluded and the 3.2 million pastures allotted to village communities included, the relevant percentage rises close to 90.

The largest groups to benefit by the reform were the farm servants and laborers, who were landless, and the dwarfholders. Of these, farm servants fared best with an average per caput allotment of 8.4 cadastral yokes. While a holding of this size may not be conducive to prosperous farming under Hungarian conditions, it is considered to be above the minimum required for a farm family. Thus the status of this group has been considerably improved as compared to its state during the interwar period.

The average per caput allotment of the traditionally most disadvantaged group, the agricultural laborers, leaves them at the upper end of the dwarfholder category. This undoubtedly represents an improvement in their social status and possibly in their economic status. Many of these laborers, immigrants before the war, have now acquired a permanent home for the first time. Whether a holding of about five cadastral yokes is adequate to

TABLE III. DISTRIBUTION OF EXPROPRIATED AREA AND PER CAPUT ALLOTMENTS BY TYPE AND NUMBER OF BENEFICIARIES

^a Churches, public pastures, state forests, etc

provide the minimum necessities for the new farmer and his family cannot be answered on a priori grounds.

Those dwarfholders who have acquired an average allotment of about four cadastral yokes have been lifted out of the dwarfholder category entirely.

A significant feature of the recent land redistribution is that about 97 thousand farm servants and 200 thousand laborers were still left landless.⁹ Assuming that these were to receive an average per caput allotment of five cadastral yokes, an additional 1.5 million cadastral yokes would have to be found for distribution. This would necessitate lowering the permissible maximum size of holding from 100 to 50 cadastral yokes. There has been some pressure in this direction, but the authorities have been reluctant to carry out such a measure because of its potentially adverse effect upon total farm production.

The agricultural employment opportunities of these 300 thousand landless are extremely limited under the new conditions. With the disappearance of the large holdings, outside labor requirements have been drastically reduced. Therefore to the extent that these landless have not found non-farm employment opportunities,

TABLE IV. SIZE DISTRIBUTION OF FARMS IN HUNGARY IN 1947,
BY NUMBER OF FARMS AND AREA IN EACH SIZE CLASS

⁹ Computed on the basis of comparisons with the 1941 Census returns on the assumption that any war losses or out-migration were compensated by natural increase.

¹⁰ These are state holdings; there are none in private hands.

they are unemployed. Thus, part of the "disguised" labor surplus which was distributed over most of the agricultural labor force has been absorbed by these 300 thousand and converted, through them, into an open and real surplus.

Before attempting to appraise further the significance or effects of these recent land measures, it is essential to examine the new farm size distribution.

There are very few privately owned farms in the country today with more than 100 cadastral yokes. The 3.3 million yokes which are in larger units are state and public properties, mostly forests. For this reason, it seems appropriate to use in Table V farms of 100 yokes and less as the yardstick in attempting an evaluation of the new land situation and comparison with prewar conditions.

TABLE V. COMPARATIVE PERCENTAGE DISTRIBUTION OF NUMBERS AND AREAS BY FARM SIZE CLASS IN HUNGARY, 1935 AND 1947

Source. See Table I and Table IV.

On examining Tables I and IV, it becomes apparent that the abolition of private estates above 1,000 cadastral yokes did not eliminate, but reduced considerably the inequities in landholding. The total number of farms was increased by almost 200 thousand as compared to 1935. The proportion of dwarf holdings (below five cadastral yokes) decreased, but the area in such farms increased sizably both in absolute and relative terms. As a result, the average holding in this group rose from 1.3 cadastral yokes to about two, which is an improvement even though it represents an uneconomical farm. However, the situation may be more favorable than this would indicate, since there are a large number of holdings of one cadastral yoke or less, located near urban centers and owned by industrial workers, craftsmen etc. Thus if the data would exclude

¹¹ The remaining 20% were mostly large state holdings.

these categories, the average holding in the dwarfholder category would be above two yokes.

The average size of holdings below 100 cadastral yokes increased from 4.6 to 6.2 cadastral yokes with the largest increase in the average of the 50 to 100 size class. This is due to the fact that prior to the new reform a much higher proportion of farms in the latter group was close to 50 cadastral yokes in size. However, with a ceiling of 100 cadastral yokes on size of farm, the larger holdings were reduced to this size, so the proportion of 100 yoke farms in the 50 to 100 yoke group increased, causing the average size of farm in the group to rise also.

It is apparent from the data cited that the 1945 reform went far beyond the land measures of the 'twenties, in that it completely abolished the latifundia in Hungarian agriculture and, by granting land to 400 thousand agricultural laborers and 200 thousand dwarfholders, created a large number of small farm units in their place. At the same time, it left about 300 thousand farm laborers landless, did not touch strip farming or customary inheritance practices, and thus left the way open for further fragmentation of holdings.

The execution of the reform was remarkably rapid. Less than three years were needed to complete this far-reaching land redistribution, while eleven years were required for a much smaller task in the 'twenties. However, the speed also had certain definite drawbacks, particularly in the early stages.

Appraisal of the 1945 Reform

The substitution of a large number of small holdings for the estates is likely to affect unit crop yields, density of livestock per unit of farm area, livestock production, crop utilization for food versus feed, share of crop marketed, efficiency of labor utilization in agriculture, and the whole pattern of farm organization. It would be premature to attempt at this time a conclusive appraisal of the economic effects of the 1945 reform. However, it may be worthwhile to indicate in broad terms the direction of the changes which may be expected under alternative sets of assumptions.

Low post-World War II yields in Hungary and other countries are sometimes adduced as proof of the negative impact of changes in farm size distribution upon farm production. But these low yields are as much a result of war devastation, consequent reduction in farm capital, and shortage of production requisites, as of

shifts in farm size distribution. It is however, true that if all other variables affecting farm production are kept constant, the net effect of far-reaching land redistribution is likely to be in the direction of lower crop, meat and milk production, with a lower share of the total farm product coming to market in the short-run.¹²

It is a handicap of most far-reaching land redistribution programs that they are usually instituted in a revolutionary post-war situation—that is, at a time which is politically particularly opportune, while it is economically most unfavorable. The establishment of a large number of new farms in a war devastated economy increases the agricultural capital requirements at a time of greatest capital stringency. Organization of new farms means more farm buildings, more tools and equipment, more livestock, and generally a higher investment per hectare. The landless agricultural laborers and dwarfholders, who comprise the bulk of the new farmers, usually have practically no savings or capital reserves, and therefore have to depend upon a disorganized and overstrained credit system.

The long-run net effects of changing size distribution, under static assumptions, are likely to lead, in addition, to a shift from wheat to corn production and to greater livestock numbers. However, these static assumptions, which are not too valid even in the short-run, become extremely tenuous in the long-run. On the basis of present indications, with government planning and intervention in the economic sphere, vigorous measures are being taken to improve farming practices. At the same time, such measures as organization of cooperative farm equipment stations may help to capture some of the economies of scale for the recently organized small peasant farms. Thus these measures may wholly or partly counteract the previously noted negative effects of changed farm size distribution.

However, to judge the success or failure of the reform on exclusively economic grounds may be misleading. This the more so since land reforms are not only economic but social and political measures as well. They are partly designed to reduce the social tensions and conflicts in agriculture by improving the status of the most disadvantaged groups. Their over-all success or failure therefore, must be judged in these terms as well.

Large landholdings which continued to be so important in Hun-

¹² This reasoning is based on the results of interwar investigations of comparative yields on small farms and on large holdings

gary up to 1945 were perpetuated at the cost of a highly depressed landless agricultural proletariat and a poverty-stricken dwarfholding peasantry. It was a system which tended to aggravate such basic economic maladjustments as pressure of population upon land resources, "disguised unemployment" in agriculture, low levels of agricultural intensity, and retarded techniques of farm production. However, it would be a mistake to conclude that land reform in and of itself can cure these economic ills. It may represent a necessary institutional pre-condition for the agricultural development of the country, but the solutions for these basic problems must be sought beyond the framework of tenure reform, in policies designed to raise the productivity of agriculture hand in hand with growing industrialization of the economy as a whole.

Rising agricultural productivity and efficiency which is a necessary concomitant of industrial development may be greatly retarded by the impediments of smallhold and dwarf peasant tenure as established by the recent reform. Agricultural development may lag considerably behind industrial development and thereby slow down the latter. Under such conditions, new economic, social, and political pressures could be built up for another radical change in the land tenure system in Hungary.

TEN YEARS OF THE FARM TENANT PURCHASE PROGRAM

EDWARD C. BANFIELD*

University of Chicago

Ten years' experience suggests that the Bankhead-Jones Farm Tenant Purchase program must be redirected if it is to serve a useful purpose in an era of high employment, rising national income, and rapid technical progress in agriculture. Many Tenant Purchase (TP) loans have been too small to make efficient use of family labor or to yield a "minimum-adequate" income when farm prices are not extremely high; indeed, some borrowers may have reduced their incomes by accepting loans. The loans have not been larger because local public sentiment and Congressional opinion would not tolerate much improvement in the status of tenants, sharecroppers, and laborers who were "on the government." Within the limits thus prescribed, it has frequently not been possible, even with the useful devices of farm planning and supervision, to create what can be called adequate units. A large increase in the amount of the average loan seems plainly called for even though land prices decline from their current high levels. But the question must be asked whether a TP program involving loans of, say, \$20,000 or \$30,000 can serve the purposes intended by the authors of the Bankhead-Jones Farm Tenant Act or, for that matter, whether it should play any important role in a national agricultural program.

So far, of course, the TP program has not played an important role. From its inception in 1937 through June 30, 1947, the period covered by this study, the Farm Security Administration (and its successor, the Farmers' Home Administration) made TP loans totaling \$293,876,733 to 47,104 families. This is a very small beginning; there were still 1,858,421 tenants in 1945 and (if this were the objective) it would take the TP program nearly 400 years to make them all owners at the rate that has prevailed so far. The significance of the program does not necessarily rest on this basis however. Its proponents have always regarded it as a demonstration which (as President Roosevelt wrote in 1937) would be ex-

* The writer wishes to thank Professor T. W. Schultz for his criticism of an earlier draft of this paper and to express appreciation to friends in the Farmers' Home Administration who, while they do not agree with the conclusions reached, were generous with their assistance to the writer.

panded "to a scale commensurate with the magnitude of the problem as rapidly as our experience and resources will permit."¹ War and inflation of land prices have postponed expansion of the program, but it may take place fairly soon and on a large scale. In the Farmers Home Administration Act of 1946² Congress provided the machinery for rapid expansion by creating a mortgage insurance program to supplement the direct loans and by increasing the authorization for loans from \$50,000,000 for direct loans to \$150,000,000 for both direct and insured loans. If, as these changes suggest, something like a billion and a half dollars may be invested in this brand of tenure reform during the next ten years, it is surely important that the record of the TP program receive careful scrutiny. In this paper the writer undertakes to, one, trace the structural development of the program; two, summarize the record of loans made; and three, appraise the part the program may usefully play in the future.

The Bankhead-Jones Farm Tenant Act

Title I of the Bankhead-Jones Farm Tenant Act³ authorized the Secretary of Agriculture to loan a tenant, sharecropper, or farm laborer whatever amount might be necessary to buy and improve a farm. The Act set no upper limit on the size of the loan and it did not require that the borrower have any resources of his own, although it did give preference—"wherever practicable"—to those who could make a down payment or who had tools and equipment for farming. The loan was to be repayable over as many as forty years at three percent interest and the Secretary was authorized to offer a variable payment plan "under which a surplus above the required payment will be collected in periods of above normal production or prices and employed to reduce payments below the required payments in periods of subnormal production or prices." The Act provided that the borrower receive a deed to the farm and that the Secretary take a first mortgage; during the first five years of the loan the borrower could not sell the farm except with the Secretary's permission.

Although it set no upper limit on the amount of the loan, or the size of the farm, the Act did in effect set a lower limit by specifying

¹ Message to Congress, Feb 16, 1937, transmitting the report of the Special Committee on Farm Tenancy

² Public Law 731, 79th Congress.

³ Public Law 210, 75th Congress.

ing that no farm could be purchased unless "of such size as the Secretary determines to be sufficient to constitute an efficient farm management unit and to enable a diligent farm family to carry on successful farming of a type which the Secretary deems can be carried on in the locality where the farm is situated."

The Act required that loan funds be distributed among the states in proportion to farm population and the prevalence of tenancy. This meant that about two-thirds of the funds would be used in the South and one-fourth in the Midwest; in other regions the loans would have to be very few and far between.⁴ This requirement also meant that funds could not be allocated from state to state to suit administrative purposes.

The Secretary was required to establish a committee of three farmers in each county where loans were to be made. The committees were to certify as to the eligibility of applicants and the reasonable value of the farms to be purchased. No loan could be made without certification by the committee and the loan could not be in excess of the amount certified by the committee

Administrative Determinations

Administration of the TP program was placed in the Farm Security Administration, which had recently been created from the Resettlement Administration. FSA brought to the new program a point of view and a methodology which had evolved from relief and rehabilitation undertakings. Its approach qualified the Act in three important ways: 1, it set an upper limit on the size of the loan; 2, it set an upper limit on the economic status of eligible applicants; and 3, it made supervision and farm and home planning inseparable from the loaning process.

The limit on the size of the loan was set at the amount necessary to buy and improve a "family-type" farm, which FSA procedure defined as follows: "An efficient family-type farm management unit is a farm which furnishes full, productive, year-round employment for an average farm family and one which an average farm family can operate successfully without employing outside labor, except during brief peak-load periods at planting or harvest time. Such a farm must have the capacity to yield income on the basis of long-

⁴ Based on the 1945 Census, the distribution was as follows: South 66.86 percent, East 2 65 percent, Midwest 21.83 percent, West 4.48 percent, and Territories 4.18 percent. With the maximum appropriation authorized (\$50,000,000), less than one loan per county could be made in 21 states.

time prices which will maintain an average farm family according to acceptable living standards, pay annual operating expenses, pay for and maintain necessary livestock, and farm and home equipment, and pay off the loan.”⁵ While the farm could not be larger than this ideal, neither could it be smaller; the “family-type” farm might vary greatly in productivity from locality to locality but it would always be no more nor less than one average family could operate without much hired labor and it would always yield “acceptable” living standards. Under FSA procedure this formula was rigidly applied. Borrowers were even required to agree not to buy or rent additional land.⁶ During 1938 an absolute limit of \$12,000 was placed on loans because some applications under the family-size formula were for larger amounts than the Act seemed to the FSA administrators to contemplate.

FSA set an upper limit on the economic status of eligibles by limiting the loans to those who could not obtain “adequate credit at reasonable rates and terms” from other sources. This meant (so far as financial status was concerned) that anyone who could not obtain a bank loan for the purchase of what FSA considered to be a family type farm was eligible. Since a farmer would need at least 25 percent of the purchase price of a farm, as well as stock, equipment, and operating capital in order to obtain a bank loan, the upper limit of financial eligibility was thus set at a fairly high level.

Farm and home planning, which had been developed in the rehabilitation program of the Resettlement Administration, was given additional importance in the TP program. The borrower had two written versions of a plan. One was an annual plan, setting

⁵ This is the language of the procedure now in effect (FHA Instruction 421.1); it is essentially the same as that which was written in 1937.

⁶ FHA Form 317 (an “informal agreement” having no legal status but suitable for framing and calculated to impress the borrower) provides, among other things, that the borrower and his wife agree not to hire outside labor except as called for in the farm plan, not to rent the farm or operate it under a share-cropper arrangement, not to rent or operate additional land, not to purchase additional land or sell any portion of the farm, to sell to a buyer approved by FHA if it should become necessary to sell, and to try to maintain the farm as a one-family farm. This was intended to achieve by voluntary agreement what the Special Committee on Farm Tenancy hoped to enforce by withholding title for 20 years—the preservation of the family farm once established.

From December 1942 until June 1946, as a war measure, borrowers were permitted to rent land but only on the basis of a written agreement reciting justification and specifying that the rental would end when the emergency passed. Even so, the procedure (Administration Letter 636) required that each exception to the rule be approved by the Regional Director. The present policy does not provide for exceptions.

up a budget for the current year; the other was a long-term plan which outlined the goals and management methods for several years ahead. The plan was supposed to be worked out by the borrower in cooperation with the county FSA supervisor and it was to be the basis of the government's educational effort with the farmer as well as an agreement or understanding between borrower and lender. The plan also served as the basis of supervision. The borrower was in more or less frequent contact with FSA farm and home supervisors.⁷ The farm supervisor was responsible for administrative procedures in connection with the loans, for planning with the borrower, for giving on-the-farm technical guidance from time to time as necessary, and for reviewing borrowers' operations in a group meeting at the end of the year. The home supervisor advised the housewives concerning household accounts, nutrition, home production and preservation of food, health and matters of home economy generally.

The farm plans (as well as the farms purchased) fell into a few patterns; in each of the major agricultural areas there is a certain size and type of farm with which the TP program has been identified. All of the farm plans—even those in irrigated sections—call for diversification. Specialization has been almost entirely excluded. Production for home use has been stressed.⁸

The Act authorized the making of loans for the full purchase price of the farm *plus necessary repairs and improvements*. FSA established certain minimum standards of land development and of construction and required that these standards be met as a condition to the making of the loan. The standards of construction were based on considerations of safety and sanitation and were extremely modest (the average cost of 9,681 new dwellings built on TP farms through June, 1941 was \$1,406); nevertheless, in a typical year one-third of the average TP loan was used for repairs and improvements. Very little of this expense was income producing.⁹

⁷ In 1944 a Bureau of Agricultural Economics survey [*Study 122* (processed) Jan 1946] based on a sample of TP borrowers in the South and Midwest showed that 90 percent of the Midwestern borrowers were visited from two to four times a year. In the South about one-third were visited three or four times, 20 percent were visited five or six times, and 22 percent were visited seven times or more. Sixty-nine percent of the supervisors reported spending from one-fourth to one-third of their time with the TP borrowers.

⁸ Recently there has been an effort by top administrators to make the farms more "commercial." See the address by Paul V. Maris, *Making Good on What FSA Stands for from a Farm Ownership Standpoint*, (mimeo.) 1946, p. 8.

⁹ The minimum standards are set forth in FHA Instruction 423.1 and 424.1.

TABLE I. PERCENTAGE DISTRIBUTION OF TP LOAN FUNDS BY TYPE
EXPENDITURE, FISCAL YEAR 1941*

Area	Purchase of farm and inci- dental costs	Land improve- ment	Buildings other than dwellings	Dwellings		Total
				New	Repairs	
United States	67.9%	3.6%	10.6%	14.3%	3.6%	100.00%
East	81.2	0.7	13.0	0.3	4.8	100.00
Midwest	81.9	2.4	9.7	1.4	4.6	100.00
South	60.9	4.2	11.1	20.7	3.1	100.00
West	78.9	2.3	7.4	6.6	4.8	100.00

* 1941 was chosen because the subsequent inflation of building costs caused curtailment of new construction. In the fiscal year 1947 "Purchase of farm and incidental costs" was 76.0 percent of the total for the United States.

Sources: unpublished data from FHA. The distribution is given in dollars by states cumulative through June 30, 1940 in the *House Hearings on the Agriculture Department Appropriations Bill, 1942*; p. 82.

Engineering and farm planning assistance were provided by FSA without cost to the borrower. During the first year of a loan these and other (administrative) costs averaged \$329.38; for the next four years the aggregate cost has averaged \$667.08, and for the remaining 35 years of the full repayment period it is expected to aggregate an additional \$1,945.65. This is a total of \$2,942.11.¹⁰

The Tarver Limit

In five successive appropriations acts beginning with that of 1941, Congress provided that no loan might be made for the purchase of a farm of greater value than the average of all farms of 30 acres or more in the county where the farm was located. This was the so-called Tarver Limit, inserted in the Act each year at the insistence of Representative Tarver of Georgia, then chairman of the appropriations subcommittee. The loans in Mr. Tarver's state had averaged \$3,900, an amount he believed to be "twice too high." In the south as a whole (as of June 30, 1939), the average loan was \$4,668 and in the United States as a whole it was \$5,402.¹¹

According to these instructions, if a borrower resists the minimum standards "the remedy is not to force him to accept such standards against his will. On the contrary, the remedy is to refrain from making him an FO loan."

¹⁰ Unpublished data supplied by FHA.

¹¹ Mr. Tarver's point of view was as follows: "We are dealing here with the very poorest class of agricultural people. I think around two-thirds of the farmers of my district are tenant farmers. I do not see the point of buying one of those men a farm worth \$7,500 when you could buy four farms, for four tenants, at one quarter of the price, which would buy a fairly good farm in my district for a tenant and one with which 99 percent of the tenants in my district would be satisfied." *House Hearings*,

The Tarver Limit varied greatly from place to place (it was \$962 in Jackson County, Ky. and \$253,525 in Kenedy County, Tex.) but in 35 percent of all counties in the United States and 60 percent of all counties in the South it was less than \$4,000. In many areas where the rate of tenancy was very high it was impossible to buy a family-type farm within the Limit.

If the loans could not be made in one county because the Tarver Limit was too low, funds could be shifted to another county of the same state. But in some states the Limit was too low in almost all counties (Alabama, for example, had only two counties with Limits above \$3,000) and funds for these states could not be reallocated to other states because the distribution of funds among the states was governed by the terms of the Act. (Alabama, for example, got six percent of the national appropriation.) In these states it was not possible to use the full amount appropriated.

The appropriations act for 1944 contained (in addition to the Tarver Limit) a limit on the amount of funds that could be loaned in any one county. This amount was set at not more than twice what the county would receive if the funds were distributed among the counties on the basis of farm population and the prevalence of tenancy, provided, however, that any county might receive at least five loans. On this basis there were only 473 counties where more than five loans could be made. The restriction meant that funds could not be shifted from county to county to avoid the places where inflation of land prices was most severe. Because of the interaction of this so-called "Fund Limit" with the Tarver Limit and because of the effects of inflation, FSA was forced to return more than one-fourth of the 1944 appropriation to the Treasury.

This political interference handicapped the administration of the program, but it probably had little effect on the size of the loans that were made. There were political forces, however, which *did* influence the size of the loans by influencing the "family-type farm" standard itself. In the South, especially, public and Congressional opinion opposed setting the TP borrower above his neighbor; if the neighbor's status was woefully low, the borrower's would have to remain low too. Moreover there was a widespread feeling shared by many FSA personnel in the South, that a very modest improvement in the position of the borrower was all that should be expected.

Agriculture Appropriations Bill, 1941, pp 953-954. A report on the size of TP loans is given in these hearings.

ted.¹² These opinions markedly influenced the local administration of the "family-type farm" standard and they account in large measure for the fact that the average loan was not larger.

The Fund Limit was intended to prevent FSA from concentrating loans in "colonies". The Act provided no authority for FSA to purchase land for subdivision. Yet in some parts of the South (the Mississippi Delta, particularly) it was almost impossible to obtain a family-type farm except by subdivision. In these places FSA optioned tracts and made individual loans to whatever number of tenants might be needed to effect the subdivision. By June 30, 1943 FSA had created 4,604 farms by subdivision.¹³ From then until Dec. 31, 1947 only 1,348 farms were created by subdivision; the rate had slowed because of the Fund Limit, because of opposition from the American Farm Bureau Federation, which claimed that the Act was being "perverted", because of the increasing cost of building, and because FSA discovered that subdivision was "a very difficult thing to do well".¹⁴ At the end of 1947 the average tract had been subdivided into 4.3 units; several tracts, however, had yielded more than 100 units.

Section 505 (b) of the Servicemen's Readjustment Act of 1944 made veterans of World War II eligible for TP loans to the same extent as if they were tenants. In the appropriations act of 1946 Congress earmarked \$15,000,000 of a \$35,000,000 appropriation for loans to veterans. These funds could be distributed without regard to farm population and the prevalence of tenancy and without regard to the Tarver Limit.

Beginning in 1943, land price inflation made itself increasingly

¹² There was a good deal of controversy as to whether Southern borrowers should have bathrooms in new houses, the idea of a cropper, especially a Negro cropper, who was "on the government" having a bathtub while his neighbor had none was too much for some people to stand. So also was the idea of the borrower's having more stock or more land. The influence of this kind of opinion on the administration of the program can be seen in the words of Frank Hancock, then FSA Administrator, in his testimony (*against* the Tarver Limit, incidentally) before the Senate subcommittee on agricultural appropriations in 1945. "I am in full agreement with what I understand to be the principle underlying this restriction (the Tarver Limit). The government should not provide loans to set borrowers up on a higher plane than that of their neighbors who are successfully acquiring ownership of farms through their own efforts, and with their own savings, without government aid." Beyond this unwillingness to see the borrowers specially favored there was, no doubt, the fear that if their rise in the world was too rapid they might become "uppity."

¹³ A record of subdivisions by states appears in *House Hearings on Agriculture Appropriations Bill, 1944*, p. 1647.

¹⁴ Paul V. Maris in a letter to the writer. Mr. Maris added that FHA would resume making subdivisions as soon as building materials become readily available.

felt. This was true although FSA clung tenaciously to a conservative system of appraisal.¹⁵ Despite precautions, however, price inflation affected the loans to some extent. "Our borrowers are probably paying more for farms or getting farms of poorer quality and location than heretofore", the director of the Farm Ownership Division of FSA said in 1946. "If we were openly to advocate a definite percentage increase in prices paid for farms, in addition to the small adjustment in long-time commodity prices, that very fact might cause an excessive relaxation."¹⁶

In July, 1946 the Bankhead-Jones Farm Tenant Act was amended by the Farmers Home Administration Act and the following November FSA and the Crop and Feed Loan Division of the Farm Credit Administration were merged into the new Farmers Home Administration. While it retained the main structure of the TP program, the new legislation made several important changes in it.¹⁷ These changes had not had an important influence on the program as its tenth year ended on June 30, 1947.

The TP Loan Record

The before-acceptance tenure status of the borrowers who had active loans in 1945 is shown in Table II.

TABLE II. PERCENTAGE OF ACTIVE TP BORROWERS (1945) IN VARIOUS TENURE GROUPS AT ACCEPTANCE

Tenure group	United States	Midwest	South	East	West
Cash or standing renter	21.7%	17 2%	21 7%	43 2%	36.1%
Share renter	63.4	80 5	59 8	38 2	48 4
Share cropper	13 3	1.6	17 1	9 3	8 0
Farm laborer	0.7	0.3	0.6	2 5	4 0
Other	0 9	0 4	0 8	6 8	3 5

Source. Computed from FHA, *Release No. 3*, "Status of the Tenant Purchase Family in 1945."

¹⁵ Early in 1948 FHA appraisers were still making their calculations on the basis of ten cent cotton in Alabama, \$7.70 hogs in Indiana, 77 cent wheat in Nebraska, and 31 cent butterfat in New York. (*FHA Instruction 622 3*).

¹⁶ Paul V. Maris, *op cit*.

¹⁷ The FHA Act made the following important changes in the TP program. 1, provided for Federal insurance of mortgages to supplement direct loans with the stipulation that the insured-mortgage borrower make a down payment of at least 10 percent; 2, increased the interest rate to 3½ percent (on insured-mortgage loan 2½ percent plus 1 percent insurance charge); 3, gave eligibility and preference to qualified veterans of all wars, 4, retained the formula for distribution of loan funds among the states but gave each state a minimum of \$100,000 and provided veterans should be served in advance of the distribution of funds for tenant loans; 5, authorized

Although the Act specifically listed farm laborers among the eligibles, virtually no loans had been made within this very large group. This was not the result of deliberate policy; FHA (and FSA) procedure does not discriminate against laborers. However, the Act and the procedure give preference—"wherever practicable"—to applicants who can make a down payment or who have stock or equipment for farming, and this provision tended to bar farm laborers. Thirty-eight percent of the tenants in the South are sharecroppers (1945 Census) but only 17 percent of the Southern TP borrowers were sharecroppers at acceptance, a fact which indicates that the croppers, while by no means excluded, receive less than a proportionate share of the loans. The same was true of Negroes in the South. In eight Southern states having more than 30,000 colored tenants 49 percent of all tenants were colored (1945 Census) but in these same states only 23 percent of the TP borrowers were colored.

The size of loans varies greatly by regions.¹⁸ In the South (as of Dec. 31, 1945) 61.8 percent of the loans were for less than \$5,000 and only 5.9 percent were for more than \$9,000. The comparable percentages for the Midwest were 8.6 and 36.8; for the United States as a whole the comparable percentages were 47.6 and 13.8.

TABLE III. ACRES IN CROPS, TP FARMS IN 1945* AND FARMS RENTED BY ALL BORROWERS BEFORE ACCEPTANCE

Area	Acres in crops		
	Rented before acceptance	Owned in TP farm (1945)	Percent increase or decrease TP over rented
United States	73	75	2.7
East	77	74	- 3.9
Midwest	122	109	-10.7
South	58	65	12.1
West	97	90	- 7.2

* Many borrowers supplemented their TP farms with rented land in 1945. The average acreage of cropland rented was then as follows: United States, seven; East three; Midwest, 17; South, five; West, nine.

Sources: Adapted from FHA, *Release No. 3*, "Status of the Tenant Purchase Family in 1945."

loans to repair, improve, and enlarge farms of less than family size and to refinance indebtedness for that purpose; 6, substituted for the Tarver Limit a provision limiting loans to not more than the average value of an efficient family-type unit in the county as determined by the Secretary; and 7, converted the variable payment plan into a conventional arrangement for prepayment.

¹⁸ The size of the loan is virtually the same as the purchase price of the farm plus repairs and improvements; only 4.6 percent of the borrowers made a down payment and the average was only \$451.

These differences resulted from local variations in the "family-type farm" standard rather than from the—for the TP program—irrelevant fact that Southern applicants had less net worth.¹⁹

Except in the South, the TP farms have less cropland than did the farms the borrowers formerly rented. However, in 1945 the borrowers were still permitted to rent additional land. This rented land brought the total farmed by the non-Southern borrowers to slightly more than they had formerly rented.

Of the 11,233 borrowers (24 percent of all) who had repaid their loans in full by June 1947, 7,598 were known by FHA to have paid from farm income and to be continuing in operation of the farm when the final payment was made. FHA has no further record of the progress of these paid-up borrowers however. As of June 30, 1947, 4,606 TP loans had been liquidated by FHA.²⁰ Some of these loans had not been paid in full; the probable loss on these was estimated by FHA at \$71,575, a negligible amount in view of the total loaned. The amount advanced to all liquidated borrowers, however, was \$23,730,074. This sum, although it would be returned to the Treasury virtually intact, had not accomplished the purpose for which it was appropriated. The reasons for these failures, according to an analysis made by FHA in 1947, were chiefly accident, ill-health and old age (22.2 percent), change to other occupations (14.6 percent), dissatisfaction with location or community (11.7 percent), and deficiencies on the part of the borrower (10.9 percent). Inadequate farms accounted for relatively few failures (6.6 percent) and borrowers' objection to supervision for even fewer (2.4 percent).

The financial status of the active TP borrower in 1946 is shown by regions and for the United States in Table IV.

The 43,050 borrowers whose loans were active at the end of March 1947 had repaid 156 percent of the amount due under the repayment schedule.²¹ Fifty eight percent of them were ahead of

¹⁹ In 1945, for example, the average Southern borrower got \$4.04 in loan funds for every dollar of net worth, while the average Midwestern borrower got only \$2.93. New York and Illinois borrowers had almost exactly the same average net worth at acceptance but the Illinois borrowers got loans averaging 60 percent more than the New York loans.

²⁰ FHA, *Liquidation of Farm Ownership Loans as of June 30, 1947* (Mimeo'd).

²¹ Schedule is the amount required to amortize the principal and interest payments within the period of the note. On a 40-year loan bearing three percent interest schedule is 4.326 percent of the loan. The term "behind schedule" is used, rather than "delinquent," because, technically, the variable payment borrower may be billed for less than schedule. Actually, of course, there must have been very few instances since the start of the war when the bill was for less than schedule.

TABLE IV. STATUS OF ACTIVE TP FAMILY IN 1946

	United States*	East	Midwest	South	West
<i>Assets, liabilities and net worth</i>					
Net worth	\$6,044	\$8,461	\$9,014	\$4,654	\$9,821
Debts other than TP	446	1,665	525	337	1,446
Chattel inventory	3,680	7,311	6,441	2,534	6,636
<i>Income and Expenses</i>					
Gross family income	4,315	7,764	6,499	3,366	8,610
Cash farm income	3,388	6,676	5,631	2,442	7,290
Non-farm income	363	467	318	356	811
Value of home-use products	565	621	550	568	510
Cash family living expense	856	1,314	1,232	700	1,552
Farm operating expenses	1,538	3,899	2,379	1,100	3,802
<i>Use of net cash income</i>					
TP regular payments	569	508	991	430	1,018

Allowable capital expenditures	488	819	879	335	1,133

* Territories excluded.

Source Adapted from FHA, *Release No 7, 1946 Status Report*

schedule by an average of \$951. Seventeen percent were behind schedule by an average of \$266.

Repayment ability and net cash income were closely associated with size of loan.

On the basis of rather rough estimates,²² it appears that a considerable proportion of the borrowers, especially the Southern borrowers, would find it difficult or impossible to meet scheduled repayments if farm prices were to fall to, say, 1928 levels. At 1928 farm prices, the 1946 production of 60 percent of the Southern and 44 percent of all TP farms would have been worth less than \$2,000. If only the cash income from the TP farm is included (that is, if the value of farm-produced food used at home and of the products sold from *rented* acres is excluded), the 1946 production of the average Southern borrower (at 1928 prices) would be worth \$748 and that of the average of all borrowers \$1,957. If from this are deducted farm operating expenses (in the same ratio to cash farm income as actually obtained in 1946) and the scheduled TP payment, the remainder (the net cash farm income after TP payment at 1928

²² These estimates were made with the assistance of the Program Analysis Unit, FHA, using state indices of farm prices provided by BAE. Their chief weakness is that the following states were omitted from the calculations because comparable indices were not available: Arizona, Colorado, Connecticut, Maine, Massachusetts, Mississippi, Nevada, New Hampshire, Ohio, Oregon, Pennsylvania, Rhode Island, Tennessee, Texas, Utah, Vermont and Washington. These states include 25 percent of all borrowers.

prices) would be \$—19 for the average Southern borrower and \$526 for the average of all borrowers.

There is, of course, a close relationship between size of loan and the borrower's level of living. In 1945 cash family living expense varied from \$447 for borrowers with loans of less than \$3,000 to \$1,236 for those whose loans were \$11,000 or more. FHA's emphasis upon improvements to meet minimum standards of health and safety (but not of convenience) has not caused the borrowers to have

TABLE V SCHEDULE STATUS OF ACTIVE FO BORROWERS,
CUMULATIVE AS OF MARCH 31, 1947

Area	Number of borrowers (percent) and average amount				
	On schedule		Ahead of schedule		Behind schedule
	Percent	Percent	Amount	Percent	Amount
United States	25	58	\$ 951	17	\$266
East	34	48	848	18	302
Midwest	21	68	1,416	11	260
South	24	57	754	19	254
West	30	48	1,355	22	362

Source: FHA, *Report of Debt Payments by Farm Ownership Borrowers as of March 31, 1947*.

a markedly higher level of living in terms of specified facilities than the generality of resident-operators. In the South, 11 percent of all resident operators and 12 percent of the TP borrowers had running water in their homes in 1944; in the Midwest, the corresponding percentages were 24 and 25. Similarly, 27 percent of the Southern and 53 percent of the Midwestern resident operators had electricity as against 24 percent of the Southern and 50 percent of the Midwestern TP borrowers. In both the South and the Midwest, however, a larger proportion of borrowers than other farmers had radios and automobiles.²³

It is not easy to judge the effect of farm and home planning and of supervision upon the borrowers. The most significant data are those contained in an unpublished BAE study, based on a sample of borrowers in the Midwest and the South, *Attitudes Toward FHA Tenant Purchase Program*.²⁴ According to this study, 26 percent of

²³ These comparisons are based upon a sample of 295 Midwestern and 388 Southern borrowers in 1944 (BAE, *Study 122*, processed, January 1946, p. 101) and the Census of Agriculture for 1945.

²⁴ BAE, Division of Program Surveys, *Study 122* (processed) January 1946

the Midwestern and 18 percent of the Southern borrowers reported they had made no changes in their farming operations since obtaining their TP loans. Those who were aware of having made changes most frequently mentioned improved methods of soil cultivation, increased use of cover crops and pasture, and increased use of livestock. Very few mentioned increased mechanization or improvements in the physical plant. The borrowers who were most apt to change their farming operations were those visited by supervisors most often.

Although three-fourths of the Midwest borrowers said they had made changes in their ways of farming, only about one-fourth of them spontaneously mentioned the Farm and Home Plan in this connection. In the South, four-fifths of the borrowers said they had made changes, but only about one borrower in 15 mentioned the plan. Very few of the borrowers had what BAE interviewers termed an "inadequate" knowledge of the details of the plan, but less than half the midwesterners and only one-sixth of the southerners had what was called an "adequate" knowledge.²⁵ The borrowers who had changed their farming practices were those who were best informed about their plans.

Planning and supervision were not unpopular among the borrowers. Half the borrowers said their plans were helpful and a larger proportion considered the supervisors helpful. Four-fifths of the midwestern and three-fifths of the southern borrowers approved of the supervisors and only one or two percent said they actually disliked to have the supervisors visit. Home supervisors enjoyed about the same degree of popularity with the borrowers' wives. One-fourth of the midwest wives and one-half the southern wives said they would have run their homes differently without the Farm and Home Plan.

The BAE study revealed no relation between the borrowers' repayment status and change or lack of change in his farming practices, however, nor did it show any connection between repayment status and the nature of any changes that may have been made.

Tenant Purchase Perspectives

"It is to be doubted", Drs. Black and Hyson have written, "if

²⁵ The interviewers asked the borrowers specific questions about six aspects of their plans. A borrower who was able to supply information in any detail on all six was regarded as having an adequate knowledge of the plan. Detailed knowledge on three to five aspects of the plan was rated as fairly adequate. Ability to describe only one or two aspects was considered evidence of inadequate knowledge.

any program for agriculture in this country should be publicly supported which does not provide a net cash income for an able-bodied farmer in the prime of his life of at least \$60 a month (in addition to the use of the farm dwelling and food and fuel obtained from the farm)."²⁶ Judged by this standard over a representative term of years, the TP program probably could not be justified in the South, where 70 percent of the loans have been made. Elsewhere, too, many of the loans would fail to pass muster if farm prices were anything less than favorable.

Attempts to define a minimum adequate farm income are of course bound to be highly valuatinal.²⁷ A more useful concept for the economist (although not entirely free of the value element either) is that of efficient size. But even if it is assumed, as it is here, that a family-type farm should be large enough, in terms of technology and capital as well as land, to employ the family labor efficiently, i.e., so as to give equal rewards (including non-monetary rewards) with comparable endeavor in other occupations, the task of expressing the standard in specific amounts of land or capital is fraught with hazards.²⁸ It is not unreasonable to say, however, that if it is to purchase an efficient family-type unit the size of the average TP loan should be doubled or even tripled. In the South, for example, a single-family one-tractor unit may require from \$10,000 to \$30,000, while in the Midwest the real estate investment for farms requiring 14 to 20 months of man labor is estimated to be as much as \$32,970.²⁹ These amounts are indicative of the situation at the present time. Over the next 40 years, the period for which the TP loans are written, national productivity will doubtless increase steadily and spectacular changes in agricultural science and tech-

²⁶ *Quarterly Journal of Economics*, November 1944, p. 25.

²⁷ This can be seen from the fact that Black and Hyson believe a reasonable goal for public programs for farmers who happen to be veterans is twice as much as for others.

In 1941 FSA leaders set a very low standard, although certainly not from choice. They set the minimum cash living expense at \$50 per year for each member of the family. This was \$250 a year or \$20.80 per month for a family of five. *Hearings of the Select Committee of the House Committee on Agriculture to Investigate the Farm Security Administration*, (Cooley Comm. Hearings), 78th Congress, 1st Session, 1943, Part 2, p. 852.

²⁸ This formulation is paraphrased from Joseph Ackerman and Marshall Harris (eds.), *Family Farm Policy*, Univ. of Chicago Press, 1946, p. 389.

²⁹ These estimates are from "Study of Agricultural and Economic Problems of the Cotton Belt," *Hearings Before Special Subcommittee on Cotton of House Committee on Agriculture*, 80th Congress, 1st Session, 1947, p. 19, and *Capital Needed to Farm in the Midwest*, Bulletin 889, Agricultural Experiment Station University of Minnesota, North Central Regional Publication No. 5, January 1946, p. 9.

nology are not at all unlikely. The amount of capital required for efficient family-type farming may therefore rise sharply. In this context, the question must be asked whether a TP program making an average loan of, say, \$30,000 would serve the purpose of the Bankhead-Jones Farm Tenant Act, or indeed, any useful purpose at all.

The TP program was conceived in the South in answer to the question, asked in 1935 by the authors of *The Collapse of Cotton Tenancy*: "What is to become of the half million to million farm families—the two million to five million individuals—who are no longer needed as cotton tenants?"³⁰ As late as 1941 the administrators of FSA were assuming that the cities could not provide jobs for these millions and that therefore the only opportunity was to improve their status on the land.³¹ Today the outlook is radically changed. A large number of farm people left the land during the war and it is now widely agreed that productive work can and must be found outside of agriculture for others who are no longer needed there.³² The function of a long-term credit program in the South today is not to create the maximum number of minimum-sized farms, but to assist boldly and creatively in the reorganization of Southern agriculture—a reorganization which, now that its technical basis exists in DDT, super-phosphate fertilizer, and improved pasture grasses, is proceeding very rapidly. For this role, the TP program with its emphasis on planning and supervision, would be wonderfully well fitted if the loans were of sufficient size³³

Outside of the South, technological advance since 1900 has caused a rapid drop in the number of inadequate farms and a steady increase in the number and size of family and larger-than-family farms.³⁴ The financial position of farmers is better than at any time

³⁰ C. S. Johnson, E. R. Embree, and W. W. Alexander, Chapel Hill 1935, p. 46. It is interesting that these authors, full of sympathy for the tenants but writing in the depth of the depression, should have recommended "small plots of minimum size required to support farm families, probably twenty to forty acres in the cotton states."

³¹ In March 1941 FSA's objective was "to reduce the number of farm tenants . . . to about one million during the next 40 or 50 years. This will mean converting tenants into owners at the rate of about 80,000 per year." *Cooley Committee Hearings*, op. cit. Part 2, p. 852. See also the "ultimate picture," pp. 860-861.

³² See the testimony of the then Assistant Secretary, Charles F. Brannan, in *Hearings on Long-Range Agricultural Policy*, 1947, p. 9.

³³ The credit requirements listed in *A Conversion Program for the Cotton South* (BAE, mimeo'd. Washington: 1945) totaled (in millions) \$2,386, broken down as follows: farm purchase or enlargement, \$850; farm buildings, \$632; equipment, \$632; and livestock, \$272.

³⁴ J. C. Ellickson and J. M. Brewster, "Technological Advance and the Structure of American Agriculture," this *Journal*, 24. 4 (November 1947) p. 838.

in our history; their liquidity has risen in recent years from about 4.5 to 23 billion dollars, a circumstance which has reinforced and accelerated the trend toward larger units. Borrowers having the larger, more efficient farms will find it easier to repay their loans (especially if amortization schedules take account of income fluctuations), but it will be harder for tenants starting from scratch to acquire enough capital for ownership; down payment requirements will be stiff.³⁵ In this outlook there is a small but useful place for the TP program in providing farm ownership opportunities for those capable tenants who are unable to make down payments.³⁶ With farm development and improvement loans, however, FHA might make a more important contribution in the Midwest and in the arid and semi-arid West; farm development and improvement (particularly as regards soil and irrigation improvements) is a field in which adequate credit has always been lacking. If the development and improvement loans were of sufficient size and if the amount and quality of supervision and farm-planning were increased somewhat, FHA might open this field with great profit to its borrowers.

Americans have always hated and feared land monopoly. Without falling into the error of creating farms that are too small, the TP program could be aggressively used to break up the large corporate land-holdings of the South and West, thus accomplishing what the Preemption Act, the Homestead Act, the Reclamation Act and many other laws have so far failed to do. This, in the writer's opinion, would be a highly desirable objective, but one justified on political rather than economic grounds.

The steady and rapid advance in the amount of resources required for efficient farming makes the infeasibility of converting large numbers of farm tenants into owners more and more apparent how-

³⁵ See J. F. Timmons, "Farm Ownership in the United States" this *Journal*, 30 1 (Feb. 1948), p. 95.

³⁶ Although no attempt has been made in this article to evaluate the developments which have taken place since passage of the FHA Act, some comment should probably be made here regarding the insured-mortgage loans authorized by that Act. To obtain an insured-mortgage loan the borrower must make a down payment of at least 10 percent. This will exclude most Southern tenants (only about one in ten of its present borrowers could have met that requirement without impairing operating capital, FHA estimates). In the Midwest, the down-payment requirement will cause FHA to select its borrowers from an even higher socio-economic group. This will mean that the gap between the amount of capital which could be rented and the amount which can be borrowed (a gap already sizeable in the case of the borrowers who receive 100 percent loans, Table III suggests) will be widened. Elimination of the variable payment feature and (in other legislation) increasing the interest rate on both direct and insured loans to four percent will further decrease any advantage the non-Southern borrower might have in borrowing as against renting.

ever. The problem of rural poverty and insecurity, it now seems quite clear, must be solved in the cities. This is a conclusion that will be resisted by many valiant people who have struggled with great skill and tenacity to make the TP program a vehicle of reform in a segment of American life which was, and still is abysmally in need of reform. But the fact—the heartening fact—is that national and agricultural productivity are moving sharply upward and, moreover, the time for more fundamental reforms is near at hand.

THE BRANNAN PLAN AND FARM ADJUSTMENT OPPORTUNITIES IN THE COTTON SOUTH

W. E. HENDRIX
Georgia Agricultural Experiment Station¹

I. Income Effect

NO OTHER major agricultural region in the United States has more to gain for itself, or can add more to the sum total of national economic well-being as a result of increased income than can the cotton South. Increased income can provide a base out of which to finance long needed capital investments in both physical and human resources—investments for which the marginal rate of return is extremely high and without which there can be no real improvement in the South's productive capacity. The necessary funds for these investments, except in a few short periods of highly favorable economic conditions, however, have not been obtainable.

The rural South probably remains the most undeveloped market to be found in the United States for the products of both factory and farm. When they have high enough incomes, southern farm people buy their share of automobiles, refrigerators, electric stoves and other conveniences and services that are a part of our modern culture. They also eat their share of a large variety of nutritious foods, much of which is shipped into the South from other farming regions. The percent of farm population in low income groups in the South is higher than in any other section of the United States as indicated by the following data.

PERCENTAGE OF FARMS (OR FAMILIES) WITH CASH SALES OVER \$400,
HAVING SPECIFIED SALES IN 1946^{2,3}

Range in gross income	Percent of all farms				Approximate net cash income
	U. S.	North	South	West	
\$ 400-999	22 0	13.7	31 9	14 9	\$ 200-499
1,000-2,499	30.4	23 3	39 6	20.6	500-1,249
2,500-5,999	27.4	34 0	20 7	26 2	1,250-2,999
6,000 and Over	20.2	29 0	7.8	33 3	3,000 and Over
Total	100.0	100.0	100 0	100 0	

¹ The author acknowledges substantial aid in the preparation of this paper from Robert G. Spitze and Waldo S. Rowan.

² Basic computations by Farmers Home Administration and B A E. Approximately 1,000,000 farms with less than \$400 cash sales were excluded because they were self-sufficient, part-time or retirement farms. As compared with 1946, farm income in 1948 will be lower than in either 1946 or 1947.

³ From Public Affairs Bulletin No. 67, Library of Congress, Washington, D. C., March 1949.

With such a high proportion of the people possessing a high propensity to consume, any increase in income to these consumers will have a healthy influence on the maintenance of a flow of purchasing power in the total economy.

The Brannan Plan aims at a continuation of the present favorable level of farm income relative to non-farm. From an income standpoint the South has much to gain from these proposals in contrast to existing legislation which provides price supports only on a few basic crops and at some 20 percent lower levels on these. If a favorable level of income to Southern agriculture can be maintained, the South has the opportunity to continue the rapid progress made in recent years in adjusting its farming economy; that is, if it does not at the same time interfere with the movement of resources out of one kind of employment into another, either within agriculture or between agriculture and the non-farming economy.

It is recognized, of course, that such a price plan as the Brannan proposal cannot supply all the aid needed by the relatively poor and inadequate farms. Supplementary assistance is needed here. Neither would this plan change the relative income standings of the low and the high income farmers, a change which is politically and economically feasible only over a long period.

II. Effect on Resource Use

Artificially fixed product price relationships provided for in price support programs can themselves be a major obstacle to a desirable use of resources. In the South, however, the fixed price relationships as proposed in the Brannan Plan are not likely to have any major effects on resource uses at least until considerable progress has already been made in farming adjustments. The responsiveness of cotton farming to price changes is greatly limited by many other, and perhaps more important, resistances. Included among these are such factors as: (a) Backing up of an abundance of cheap, unskilled, untrained labor on farms as a result of high birth rates and occupational immobility (b) The forms and amounts of capital which are adequate and appropriate for cotton farming, but inadequate and inappropriate for many other kinds of production. (c) A high percentage of tenancy which hinders development of long-time farm production plans and thus closes to many people otherwise feasible adjustment opportunities. Where farmers in the South have been able to overcome these obstacles, they have been

able to make adjustments that have been profitable under any recent historical set of price relationships. In the future these will continue to be the crucial considerations rather than the precise level of cotton prices relative to other farm products. Actually, during the recent decade of high prices for agricultural products, there has been a sizeable shift from crop to livestock production in the South.

CASH INCOME FROM THE SALE OF CROPS AND LIVESTOCK
SOUTH CAROLINA AND GEORGIA, 1940 AND 1948

	1948	1948	1948 as percent of 1940 ⁴
Livestock and Livestock Products	\$ 51,650	\$232,598	450
All Crops	190,258	640,018	336

This shift was made at a time when the prices of milk and beef were favorable in comparison with cotton and tobacco and perhaps even more important when the level of income to farmers was high and labor was relatively scarce. The Brannan Plan proposes to maintain livestock prices at this favorable level in addition to a relatively high support level for the crops. The maintenance of these recent price and income relationships would, of course, facilitate continued adjustment in the South to livestock. In contrast, existing legislation offers no assurance that livestock products will not drop to a level unfavorable to that of cotton and tobacco even though these are supported at somewhat lower levels. To the extent that additional price certainty would result in more production of supported perishable products due to shifts in enterprises, the consumers will realize more abundant supplies and lower food costs. With the large amount of resources not fully employed and the relatively low income pattern, the South stands to gain here with lower food costs and subsequent higher standard of living for both its urban and rural people.

Price certainty, however, is not to be confused with market certainty. In his statement on April 7, Secretary Brannan stated: "For fluid milk, marketing agreements and orders should be continued." High price guarantees secured by marketing quotas, instead of facilitating the conversion from cotton to dairying, can very effec-

⁴ Prices of both livestock products and crops in 1948 were around 300 percent of 1940.

tively hinder such conversion. Much depends here, as is the case with many other phases of the Brannan proposal, upon choice as among the various alternatives suggested in the plan for the maintenance of high support prices.

Under the new proposal two of the so-called basic commodities have been deleted in Brannan's priority list. Though these crops, peanuts and rice, are not so important relative to tobacco and cotton, they are the sources of much of the income in certain sections of the South. Peanut producers usually can shift to other production and this industry is realizing new markets that may affect the price level. However, acreage allotments are already in effect. Peanut producers would have an alternative market through hog production in areas where there is adequate fencing. Rice on the other hand, is grown in areas where alternative use of the resources is restricted.

There is little warrant for the fears that artificially supported high farm incomes will intensify the problem of population pressure on land resources. It is doubtful that any recent set of price relationships is an adequate explanation for the origin of this problem. And in turn, it is doubtful that the solution of this problem is to any appreciable extent contingent upon changes (at least any immediately foreseeable changes) in price relationships. Involved in this problem of population pressure on resources is the production of human beings. This is a kind of production in which the South, at least in numerical terms, excels other farming regions. It is perhaps, even more than cotton, the South's major surplus product. When this product clears the market at a fairly remunerative level, cotton also clears the market at fairly good prices. When labor is cheap enough cotton can be grown at a very low level of prices. Attempts to deal with this surplus of labor solely from the demand side may give temporary relief, but only temporary relief if the present high level of labor supply continues.

In many parts of the South, of course, there are few opportunities for a marked change in the allocation of resources without the movement of large numbers of people off the farms and without a corresponding increase in the supply of capital. But even this is an over-simplified statement of the obstacles to agricultural adjustments in the South, as is perhaps well illustrated by what has happened in Greene County, Georgia, in the last few decades. In

Greene County the Soil Conservation Service in its land-use capability survey classified approximately 144,000 acres of land as suitable for cropland uses. Yet in 1944, cropland harvested was only 51,296 acres. Here acres of cropland used per farm family averages about as low as it was before nearly half the farm families, under the tremendous impact of the cotton boll weevil, moved away in the 1920's. Judged by the amount of land in use per farm family one finds here as great pressure of population on resources as occurs in most parts of the South. Yet not infrequently, one also finds many farm families living on farm units that have as much land idle as is in productive use—land that is about as productive as the land in use.

Recognizing the tremendous adjustment opportunities and problems in this general part of the Piedmont, the Farm Security Administration selected Greene County as the location for an intensive credit program. To the present time, slightly more than 1,000 farm families in the county out of an estimated 1,600 farm families now in that county have received liberal credit and intensive supervision under terms of the Farm Security Administration or its successor, the Farmers' Home Administration. Consequently, in recent years there has probably been little capital rationing in the county in any meaning of that term that is relevant to action.

On the whole, this program has accomplished much good, especially viewed from the standpoint of the tremendous difficulties faced. With liberal credit and supervision, a few farmers in the county have made the conversion from cotton to combination cotton-livestock farming. Several of these beginning with a minus net worth have paid for their farms and for capital additions needed for conversion in type of farming in three to five years. But it remains that for the majority of farm families aided by the Farm Security Administration in this county, there seems to be little hope of increasing their incomes by internal farm adjustments, unless they can do so using one-mule farming equipment and producing their usual acreage of cotton combined with feed and food production for farm and home uses. Records covering several years of their experience indicate that more capital than can be effectively used for such limited purposes on these farms is an economic waste. This is not because of any scarcity of land suitable for an expansion in their farming operations, nor because they lack access

to capital, but because with their valuations and their ideals and purposes, it is an almost insurmountable task to induce them to make the change from cotton to other kinds of production. Increased investment in education will necessarily have to go hand in hand with increased investment in physical capital goods if those physical capital goods are to increase the productivity of these workers. But adjustments necessarily have to begin with these people as they are. Because of their age, size of families, lack of education, and other limitations, it is also doubtful that many of these farm families would fare much, if any, better in non-farm employment of the kinds available or of the kinds for which they are now fitted.

If this same general situation is fairly widespread in the South, then there are many people for whom cotton production is about their only feasible production alternative, whether cotton is 27 cents per pound or only 10 cents per pound. Whatever else one may say of the problem of rural poverty or of rural welfare (within which category the problem of economic efficiency in its broader social context would seem to be embraced), it is at least a problem for which remedies cannot be easily superimposed, even by over-all price support programs. Indeed, apart from an increased awareness of the existence of problems on the part of the people who themselves are most affected, including an awareness of means suitable for their solution, there is probably no adequate solution at all. Increased educational opportunities can help people develop the values and ideals without which they have little incentive to change. A high price and income policy is likely to have little effect here except as it may indirectly increase investment in the education and cultural development of the people.

III. Production Control

In the first section of this paper the importance of a high level of income was stressed as a means of facilitating farm adjustments in the South. The second section attempts to point out the limitations of relative prices in bringing about a desirable allocation of resources in the South. But over the long pull, and to the extent that these other barriers to efficient resource use are overcome, relative prices will guide resource use in the South as elsewhere.

This section will be devoted to a brief statement of the conditions within which production controls may be used to improve farm

income and resource use in the South. In the interests of brevity the discussion will be limited to cotton. Acreage allotments and marketing quotas for cotton appear to be a certainty under existing legislation as well as under Brannan's proposals. What benefits can be expected from them? The demand for American cotton is a part of a broad demand for fibers. The supply of American cotton is a part of a highly competitive world supply of cotton and other fibers. It should be obvious that cotton prices determined by these influences cannot be raised significantly by restrictions in the supply of American cotton alone. Unless cotton is moved into other countries with the help of a subsidy, cotton growers would lower their income from cotton rather than increase it by production restrictions.

Yet because of the probable severe undesirable income effect on cotton producers in the years immediately ahead, if cotton prices were allowed to fall to free market levels without income supplements, price supports and acreage restrictions may assist Southern farmers in making the necessary adjustments in their farming operations. If livestock prices can be maintained at relatively favorable levels, and if aggressive educational and credit programs can be organized as a supplement to the price support and marketing quotas for cotton, resources freed from cotton production may be diverted into livestock production at a fairly rapid rate. The important considerations are that appropriate government export programs be developed to maintain a reasonably large export of American cotton, that domestic cotton prices not be maintained at levels which significantly stimulate increased substitution of domestic synthetic fibers and that cotton prices not be held at such high levels relative to other farm commodities such as livestock products, as to remove the present economic incentives for shifting to diversified farming operations.

If production controls are utilized to implement price supports for cotton within these limitations, significant progress should be made both in the organization of cotton production and in the substitution of livestock for cotton, lessening the need for continued export subsidies and government income supplements in the South.

IV. Conservation Measures

With a predominance of row crops, long seasons of exposure, a dense population in agriculture, and low farm income, much of the

soil in the South has been badly depleted. A commendable beginning has been made on this problem by the various educational agencies, A. A. A., and Soil Conservation Service. In addition to the understanding of the need and method of conservation, farmers must see a security of return on their time and money in the short run to invest in the soil.

So far price supports to maintain an adequate income for farmers have had only an indirect relation to programs designed to encourage conservation. Farmers often fail to see the contribution conservation practices make to income received for their production. The Brannan plan proposes to tie these two segments of agriculture together in two ways. To the extent that conservation practices mean more forage crops, proposed price supports on livestock products assures farmers a favorable return for them. Even more directly a farmer must meet minimum conservation requirements in his farm plan to be eligible for price supports under the new proposals. Of course the requirements for conservation in this plan are unknown and subject to suspicion. For the South, it must be realized that measures to improve conservation of the soil within socially acceptable means meet a dire need. Certainly the maintenance of a high level of income and the supporting of livestock prices at a favorable level with crops are additional factors in the plan to encourage conservation.

V. Other Provisions Needed

The Brannan Plan, even though the level of price supports remained at proposed 1950 levels, would be a major improvement over existing legislation. But if enacted into law the Brannan Plan should be amended to provide for more price flexibility, at least in the event sufficient funds are not appropriated to accomplish the income objective of the program. Otherwise, it may result in widespread economic displacement. It might also be amended to extend the compensatory payment approach to storable commodities. (With modern food preservation methods much of the validity for the distinction between perishable and non-perishable commodities disappears, with the distinction if valid turning more on economic than on physical grounds.) For cotton, however, if we can assume that the government would institute an effective resale program, disposing of excessive stocks at world market

prices, then the compensatory payment approach, as opposed to loans (that in effect likely may become direct purchases), would do little more than add to administrative costs. The loan or direct purchase approach would mean, of course, that government would perform more of the trading functions, a likely objectionable feature from the standpoint of the cotton trades industry.

An income support program tied to commodity marketings obviously is not a solution of the income problem of farm people who produce little or nothing to sell. This perhaps is the major weakness of the Brannan plan from the standpoint of many Southern farm people. On the other hand, there probably remains to be worked out what is a politically feasible plan of national income distribution adequate for the solution of the income problem of extremely low income farm people.

Presumably price support programs for Southern crops, especially cotton and tobacco, are predominantly programs for helping low income farmers. Out of 1,589,706 farms reporting cotton harvested in 1939, almost 80 percent, 1,243,464 reported fewer than eight bales of cotton harvested. These farms accounted for 49 percent of the acreage and 37 percent of the cotton produced. The significant economic fact is that this large group of farmers, almost all of whom were in the A.A.A. program, had an average value of farm products sold, traded, or used by the farm household of \$560.⁵

Essentially the same situation prevails for tobacco. Even more farmers are growing small acreages of tobacco than before allotment programs were started. Probably 75 to 80 percent of all farmers reached would be classified as low income farmers.

With but a few modifications the Brannan plan contains no new provisions that could not be found in present and past agricultural legislation. Enacted with a view to early amendment wherever experience reveals it to be inadequate or inappropriate in either means or objectives, or preferably provided sufficient discretionary authority for its administration, including authority for more flexible prices, the Brannan plan may be instrumental in effecting a more orderly adjustment in agriculture during the post-war years. Certainly the administrative authority should be broad enough to prevent a recurrence of such wastage as that in the

⁵ Census of Agriculture: 1940, Special Cotton Report, page 2.

present potato program. At best any approach to the income problem of agriculture may be attended by some wastage of human and physical resources, including a free price policy, if southern economic history has any meaning for this problem. It is also doubtful that anyone has thus far found a single simple answer to either the farm price and income policy issue or to the problem of agricultural adjustments in the south.

GREAT PLAINS AGRICULTURE AND BRANNAN'S FARM PROGRAM

HAROLD G. HALCROW AND ROY E. HUFFMAN
Montana State College

THE agricultural program presented to Congress by Secretary Brannan in April and May departs in several respects from the programs which have been followed since the early days of the New Deal. A revised concept of parity which places the base for computation on income rather than on price, a change in method of stabilizing farm income, a device for preferential treatment of the family farm, and a greater emphasis on farmer responsibility and initiative for instituting production or market controls are main features of the original presentation.

Brannan's program is based on the idea of maintaining farm income through (1) production payments on non-storables, and (2) high support prices for storables. The non-storables account for about 75 percent of the gross income of agriculture. Prices for these would be allowed to seek the market level and prices for storables would be maintained according to the new support formula. The reaction of farm leaders to the program has varied from coolness to outright opposition, the chief exception being the Farmers Union.¹ Most of the producer groups which have testified have indicated their preference for price support rather than production payments whenever the choice has to be made. Some have indicated that they would favor rather strict production and marketing controls if necessary to maintain the prices of their products.²

Arguments advanced by Brannan when presenting his program and arguments advanced in most of the testimony which has fol-

¹ See *National Farm Program*, Hearings before the Committee on Agriculture, House of Representatives, 81st Congress, 1st session, April 11-May 19. See especially the testimony of the following organizations: Farmer's Educational and Co-operative Union, April 27; the American Farm Bureau Federation, April 28; The National Grange, April 30 and May 12; American National Livestock Association, May 2; National Woolgrower's Association, May 2; The Texas and Southwestern Cattle Growers Association, May 2; National Cooperative Milk Producers Federation, May 3; National Potato Council, May 4; National Council of Farm Cooperatives, May 10.

² This statement applies especially to the testimony of the National Cooperative Milk Producers Federation and the National Potato Council. An exception is the National Woolgrower's Association testimony. The American National Livestock Association reiterated their opposition "to governmental subsidies and controls." See references cited in footnote 1.

lowed appear to develop from the major premise that depressions in an economy such as ours are "farm bred and farm led." This premise, which may or may not be tenable, has focused attention on *how* agricultural income is to be supported rather than *is* it to be supported. If the premise is accepted a choice between the methods available for supporting income is imperative. The split between the producer group solution in the interest of their own welfare, and the solution in the interest of the general welfare may become the central issue. The interest of the general welfare may become so apparent as to force adoption or modification of certain of the proposals which are being debated. In spite of recent testimony, this action may be hastened by difficulties of administering the current price support program.

How would Brannan's program work in the Great Plains and what modifications may be suggested? Would it provide farm income stability and increasing efficiency in production? Or would it put Great Plains farmers in a production strait-jacket without corresponding income compensations? A definite answer to these questions cannot be made at this time because the answer depends on the level at which controls may be instituted and the conditions which are attached to production payments, price supports, etc; but it is possible to appraise the merits and the shortcomings of the broad outline presented by Brannan.

What does the Great Plains area require in an agricultural program? The area is peculiar in two respects: (1) the extreme variability or flexibility required in operations to reach maximum efficiency, and (2) the extreme variability in income associated with a fluctuating dry-land crop and range livestock economy. Furthermore, in some areas of the Plains specialization in a single enterprise—typically wheat, beef cattle, or sheep—is the rule rather than the exception. The program which would be best adapted to the area should do the following: (1) promote increasing efficiency in resource utilization; (2) counteract the extreme instability of income; and (3) move toward an expanding level of real income and greater social welfare. What does this involve?

Resource Utilization in the Plains

Great Plains agriculture is still in a stage of rapid readjustment. The overcapitalization following World War I, the forced liquidation of the early '20's and the drouth and low prices of the '30's,

have been followed by an unprecedented boom. The boom is the result of high prices and of unusually favorable weather accompanied by rapid advances in technology. The number of farms is declining and farms are still growing larger (Table I).³

TABLE I. NUMBER AND AVERAGE SIZE OF FARMS IN THE GREAT PLAINS STATES

States	Number of farms		Percent decrease in number	Average acreage per farm ^a		Percent increase in size
	1935	1945		1935	1945	
Montana	50,564	37,747	25.4	940	1,557	65.6

Source. United States Census of Agriculture, 1935 and 1945

^a In 1935, large acreages of "free" land were used by ranchers without legal control and these acreages were not included in the census reports as part of the farm unit. Since then, competition for the use of grazing resources has forced operators to lease or buy most of this land and the acreages are included as part of the farm unit in later census reports.

If public programs do not limit the size of farms, the trend on the Great Plains toward fewer but larger farms may continue for some time. The major wheat growing areas of the Plains, and much of the agriculture of irrigated areas appears suited to a high degree of mechanization which is easily adapted to the larger farm units. Ranches have been changing in four respects. (1) Existing ranches have expanded to the extent that nearly all grazing land is now under the legal control of some operating unit. (2) Fewer animals are being grazed on a given acreage. (3) Costs per animal unit have risen. (4) Capital position of the typical rancher has improved.

The combination of high prices and above normal rainfall which has occurred since 1941, within a setting of increasing mechanization, has resulted in a marked expansion in wheat acreage.⁴ Land

³ The trends shown in Table 1 appear to have accelerated since 1945.

⁴ In the Plains area of the 10 Great Plains states more than four million acres of grasslands were broken for crop during 1945-48. The breakdown for individual years

which was submarginal for wheat production in the '30's became highly profitable for wheat during the war and the early post-war years. With lower rainfall or lower prices the margin will roll back, but not to the former levels because of the greater efficiency of modern equipment and of improvements in varieties of crops and tillage practices. The Great Plains has fulfilled and probably should continue to fulfill its traditional part in American agriculture—that of being the most elastic and yet unpredictable factor in crop production.

Mechanization has brought a change in the cost structure for both crop and livestock production. A higher proportion of costs now require cash outlays. Increased expenditures for fuel, machinery purchases and repairs, are associated with lower labor requirements. With mechanization, cash costs have become rigid under a given scale of output.⁵

Policy and Program

What is required of a farm program to increase the efficiency of Great Plains agriculture? First, the program must be consistent with the need for production adjustments and flexibility in land use to reach a level of efficient resource utilization. It must not freeze the production pattern in any area. It must encourage shifts in production which will prevent the accumulation of "burdensome surpluses." Second, the program must be one that will increase the stability of production and marketing operations through adapted programs of storage, credit, crop insurance, taxation, and income supports.

Production adjustments In Brannan's original testimony he stated that "the program I have presented is designed to raise the effi-

is as follows. 1945— 667,184 acres

1946— 853,572 acres

1947—1,335,956 acres

1948—1,469,926 acres

See R. I. Throckmorton, "Report of Conditions in the Great Plains as of July 10, 1948," *Proceedings of the Great Plains Council* for July 29, 30, 31, 1948 (mimeographed), pp. 34-39.

⁵ If output is allowed to vary, the cost structure may be more flexible in certain respects than it was prior to mechanization. Evidence is accumulating which indicates that reasonably accurate yield forecasts can be made about the time of seeding which may encourage farmers to alter their scale of operations on a year to year basis to a greater degree than was profitable in former years. See A. L. Hallsted and O. R. Mathews, *Soil Moisture and Winter Wheat with Suggestions for Abandonment*, Kansas Agricultural Experiment Station Bulletin No. 278 (1936) and Ray F. Pengra, "Crop Production in the Semi-arid Regions and Insurable Risk," this *Journal* XXIX (1947), 567-70.

ciency with which resources are used in agriculture." In regard to adjusting agricultural production he said "careful consideration must be given to providing a combination of production and marketing adjustment measures to balance supplies with demand. . . . Marketing quotas and acreage allotments should continue to be available or be provided for such commodities as tobacco, cotton, wheat, rice, corn, and peanuts, with improvements based on experience . . . acreage allotments and marketing quotas should be available for use on other feed grains. . . . The legislation should provide for acreage allotments, marketing quotas and marketing agreements and orders for fruits, vegetables, and tree nuts. . . . The time may come when marketing quotas or similar feasible devices may be desirable for meat animals, dairy products, poultry and eggs, although the need for improving the diets of consumers and for encouraging conservation farming would not so dictate at this time. . . . Eligibility of a producer for participation in the benefits of any price support program should be conditioned on compliance with or adoption of applicable programs of production adjustment, marketing quotas or agreements, and the carrying out of reasonable conservation practice requirements."

Would such a program lead to efficient resource utilization in the Plains? If these regulations are to be the major factors controlling production decisions the answer must be largely in the negative. Administrative controls imposed on acreage would delay the needed adjustments and would destroy the flexibility required for efficient resource utilization. If wheat prices, for example, are maintained by production controls above some point of "normal" market equilibrium and if acreage cuts are made percentage-wise as in the case of the AAA, this would take good land out of production as well as leave land in wheat production which would be submarginal for wheat at the "normal" market equilibrium price. If these regulations are only for standby purposes for emergency use their adverse effect on the efficiency of resource utilization should not be great.

How would Brannan's program lead to shifts in production which will prevent the accumulation of "burdensome surpluses"? The program places emphasis on two price techniques: (1) price supports for storables, and (2) production payments for non-storables. The storables of the Plains are mainly wheat and the feed grains. Commodity loans and purchase agreements, if tied closely to an historical base, might bring the very thing which broke the Farm Board

and which was about to break the price support of the CCC in 1942 before the development of the wheat feeding subsidy program. Apparently in Brannan's plan, wheat prices would be held at some relatively high level regardless of world wheat conditions, of the price existing for hogs and cattle, or of the supply and carryover of wheat and other grains. Wheat could only move into world markets and feed uses with the help of government subsidies. Domestic human consumption of wheat is about half or less than half of the wheat marketed during the past three or four years. While Great Plains wheat farmers probably would like to see wheat prices stabilized at 90 to 100 percent of "parity," it is equally obvious that this is the major thing that cannot be done without some combination of drastic marketing quotas, plus consumption, feeding, and export subsidies.

To the extent that the Agricultural Act of 1948 allows greater price flexibility than the Brannan proposal, it would bring about production adjustments with less administrative control than would be required in the use of Brannan's plan. As a vehicle to achieve optimum resource utilization the price flexibility of the 1948 act is to be preferred; but Brannan's plan should provide a higher level of income and greater income stability. The more desirable feature of each might be contained in a law which provides (1) price flexibility with certainty through forward prices and (2) income stability through direct income payments based on the general index of agricultural purchasing power.

The use of price supports on the basis of whether the products are storable or non-storable would result in greater price certainty for feed-wheat and other feed grains than for livestock; which may cause a shift away from the livestock economy.⁶ Rigid price supports for grains without corresponding and consistent price guarantees for the end products may make feeding operations unprofitable in certain short run periods. A sporadic type of livestock feeding operations might result.

⁶ Because of changes in political complexion, the success of such a program to encourage expansion of the livestock industry may depend on the farm operators' confidence in the Government's fulfilling its commitment to make production payments on livestock and livestock products which offset the feed purchased or produced at high support prices. Many operators had their confidence severely shaken by the unfortunate "80-cent situation" in connection with wheat for foreign shipment in early 1946. Continually changing OPA rules on meat prices and rationing during the war always seemed to the feeder to come after he'd made his purchases of feeders but before he'd sold them. Many feeders became conservative in their operations to reduce their loss potential under this unpredictable market factor.

The support prices proposed by Brannan would depend on historic patterns and after the program had been in operation for a decade or more the level of price support would be based on the previous level of administered prices. In the Plains, where shifts in land use are rapid, price certainty would appear to have a greater effect on the efficiency of resource utilization than in areas where land use patterns are less changeable. It seems important, therefore, that the elements of price certainty which are written into the program should be flexible enough to facilitate shifts in resource utilization in line with market demand. This presents a strong argument for a forward pricing system for all the major marketable products of the Plains.

Conservation. The emphasis which Brannan places on conservation is properly placed but it is unlikely that significant advances in conservation will come through an acreage control program. Rather they should come through farmer-education services and if this does not achieve the degree of conservation considered desirable resort should be made to soil conservation payments for stated operations or practices.

Storage. There is a strong case for storage operations to stabilize the supply of feed grains. The wholesale liquidation of livestock from the Plains region during the drouth of the 1930's is well known. In many cases livestock were sold in extremely poor condition; and in some cases liquidation cut heavily into the foundation breeding herd. Periods of drouth varying in intensity and duration may be expected to recur. What kind of price-storage policy is desirable to provide a cushion against this sort of thing? It appears to be a policy which will permit storage stocks to accumulate during years of good crops and which will encourage their use as feed during years of poor crops. The maximum limit of these stocks as determined by the storage capacity available should be two or three times the current storage capacity in the Plains. This means that farm storage facilities should be expanded especially and that policy for storables should emphasize their use as an intermediate product. Brannan's emphasis on increases in storage capacity seems particularly applicable to the Plains, but in carrying out this policy, stable feed supplies rather than price support should be the major goal.

Credit policy. A basic weakness inherent in the Great Plains settlement pattern—inadequate land resources in the farm unit—

might be corrected in part through credit policy. In recent years some units have increased toward the upper limit for family sized farms due to reinvestment of a large volume of savings. If this trend is considered desirable, to obtain increased efficiency in production, it could be accelerated by placing less emphasis on the owner's equity and more on potential earning capacity—less emphasis on the existing farm unit and more on the goal of the adjusted farm unit. Brannan's suggestion for an "expansion in the Farmers Home Administration" could strengthen or retard this adjustment depending on the objectives to be followed under the expanded administration.

Adequate sources of credit should be available in bad times as well as in good times. In the past some credit sources have competed wildly in periods of prosperity but have left the Plains farmer flat in periods of crop failure or low prices. These policies, whether intentional or not, have contributed in an important way to the boom-bust situation in the Plains. It may not be too much to require that the governmental agency in the credit field also act as a balance wheel.

Crop insurance. Crop insurance, which Secretary Brannan recommends for expansion, fits into the general resource plan. The question of crop insurance does not appear to be one of policy. Rather it is a problem of developing the correct actuarial structure, as outlined elsewhere.⁷ Crop insurance may have the important effect in resource utilization of providing the equivalent of yield certainty. An expanded crop insurance program therefore appears as a necessity in working toward an efficient resource utilization pattern in the Plains.

Income Instability in the Plains

Income instability of the farmer in the Plains arises in the main out of two phenomena: (1) price instability and (2) yield instability. Income instability has been magnified over the past 20 years in the interaction of these two factors since drouth and low prices occurred at the same time in the '30's while bumper crops and high prices have been experienced simultaneously since about 1941 (Table II). These combinations have resulted in a greater aggregate income and in greater variability in income over the

⁷ See "The Actuarial Structures for Crop Insurance," this *Journal*, XXXI 2, 418-448.

20-year period than would have occurred if the highs and the lows in prices and in yields had been in some other combination.

The income instability of the operator in the Plains varies by type of farm or ranch. All operators are affected by market-price changes but the production stability of the three main types of agriculture—dry-land crops, ranching, and irrigated farming—is markedly different. The dry-land farmer and secondly the rancher are most vulnerable to changing weather conditions whereas the irrigation farmer is the least vulnerable, especially where water supplies are adequate.⁸

Policy and Program

If income instability is to be reduced two elements must come into the picture (1) A type of crop insurance must be developed which can be effective in dry-land and ranching operations. (2) Price stability must be increased or compensatory price payments must be made to counteract some of the price instability. But such payments should be made on the basis of average sales over a

⁸ The rancher's gross income fluctuates less than that of the dry-land farmer (1) because wheat and other grain crops usually are more sensitive in response to variations in the seasonal distribution of rainfall and to small differences in total precipitation than is range grass, and (2) because a dry year is a time of liquidation for the rancher, a wet year is a time for building up his herds, whereas the dry-land farmer who normally has a poor crop in a dry year may have little to sell in such a year. In a season of crop failure a wheat farmer also has to replace his seed.

period of years, rather than on the sales of the current year as under Brannan's proposal, to avoid adding to the income instability caused by variable crop production.

In periods of low agricultural income it is not clear whether agriculture faces a short run cyclical disequilibrium or a long-run secular income disparity. If it is the former the compensatory price payments of the low price years could be balanced by taxes in the higher price years. In the Plains, especially in case of some of the farmers with higher incomes, the assessment of the personal income tax on the peak incomes of some of the past few years may actually work in such a manner. It might be possible to go further in this direction by applying the withholding feature of the general income tax to farm product sales.⁹ Perhaps this might be supplemented with an additional tax which would be levied only in years of high prices.¹⁰ It is not clear how far society should go in this direction but at least payments such as Brannan proposes could be defended more effectively if a definite policy is formulated along these lines.

Real Income and Social Welfare in the Plains

Real incomes of farm families in the Plains differ greatly. Gross incomes in any one year cover wide ranges (Table III). In addition to the wide differences in gross incomes, there is lack of

uniformity in the availability and adequacy of public services. Some families are located on all-weather highways close to good schools and large markets, while others are relatively isolated. About half the farms and ranches in the Plains are served by central station electricity. The combination of home and public facilities that may be available to the family in the Plains differs considerably from home to home and from area to area. Some of these differences may be justified on the grounds of just rewards for good management, hard work, and savings; but not all of them can be justified on these or on any other grounds.

Policy and Program

How can real income be expanded and how can a greater social welfare be achieved in the Plains? In focusing attention on aggregate income the question of expanding real income and of increasing social welfare may be overshadowed. Production payments as well as price supports tend to help farmers in direct proportion to their level of output, thus favoring the farmers who already have achieved a reasonably good income position. The problem of rural poverty—in the Plains or elsewhere—cannot be solved alone by price policy, credit, or income payments. These devices may hinder rather than promote the necessary mobility for an expanding real income and greater social welfare. A credit policy with the objective of developing “economic” family farm units, more help for rural education, improved rural health facilities, expanded nutrition and housing programs, more Federal help in providing all-weather farm to market roads, an expansion in rural electrification facilities—all these should receive greater emphasis.

In his concluding remarks Brannan recognized the need for “a program for job training and placement and some definite means of encouraging the development of industries in underdeveloped areas . . . the conservation of agricultural resources . . . an expanded soil-conservation program . . . community services such as electrical and telephone services and health and educational facilities . . . research and education in agriculture and home economics . . . cooperation credit . . . the school lunch program . . .” Also Brannan recognized that his price support program “falls short of meeting the needs of those operators who lack enough good land and enough capital to produce the necessary volume with the necessary efficiency for a good living . . .”

What appears to be called for in the Plains is an expansion especially among the medium and smaller family farms to overcome their land deficiency. In fact it appears conclusive that the only way to achieve a higher real income and greater social welfare among the farm families of the Plains is to increase the mobility of the excess labor resources and to provide employment for these people through industrial development. If this is achieved, the aggregate "cost" of the program to the taxpayer—which is the subject getting the headlines—could be reduced to a minimum in the long run and yet farm families, except the most isolated, could achieve a parity of real income. In the meantime two things should be emphasized. (1) The transition from the war to the peacetime economy should be undertaken with income supports which increase rather than restrict the mobility of labor. (2) The shift toward optimum resource utilization, which is still progressing in the Plains, can be made most easily if administrative controls over acreage and output are reduced to a minimum. In this manner, agriculture in the Plains may achieve a real parity income without looking forward to a long era of production payments.

HIGH LEVEL SUPPORT PRICES AND CORN BELT AGRICULTURE

D. GALE JOHNSON
University of Chicago

IF ANY benefits are to accrue to American agriculture as a result of a farm program similar to that advanced by Secretary Brannan in April of this year, the Corn Belt is in a position to command a large proportion of the benefits.¹ The Corn Belt had something less than 20 percent of the farm population in 1945, and sold roughly 28 percent of the total farm marketings in 1947 and 1948.² With 18 percent of the agricultural labor force, the six states produced 27 percent of the total agricultural income in 1945.³

Any program that will increase farm income by increasing prices will have a "favorable" impact upon a commercial agriculture with a relatively high productivity per labor input.

The economic effects of the Brannan proposals may be considered under two heads—resource effects and income effects. Since part of the resource effects will depend upon the income effects, I shall consider the latter first

Income Effects

The income effects of the Brannan proposals will depend upon the relation between the support levels and the levels that would otherwise prevail in the market. If market prices should be above the support prices, the main impact of the program would be to reduce price uncertainty. I believe this would make the income distribution within agriculture somewhat more equal. The small farmers are subject to a greater degree of capital rationing and are in general somewhat less venturesome. This would make it possible for them to expand the quantity of resources at their command to a somewhat greater extent than the farmers with larger firms.

But I cannot believe that a ten-year moving average of prices, adjusted by the purchasing power of farm marketings, would almost exactly reflect the equilibrium prices for farm products. No

¹ The Corn Belt, as I view it, includes the eastern portions of Kansas, Nebraska, and South Dakota, the southern half of Minnesota, the northern half of Missouri, and all of Iowa, Illinois, Indiana, and Ohio. However, my analysis is based on data for the six states—Minnesota, Missouri, Iowa, Illinois, Indiana, and Ohio.

² BAE, *Net Farm Income Situation*, Jan, 1949, p. 6

³ *Ibid.*, July, 1946, p. 18

one will question that individual product prices will depart from the prices indicated by such a formula. It is also unlikely that the average level of market prices will approximate the average level indicated by the formula. I would guess that after the current heavy export demand for U. S. food subsidies to roughly its pre-war aggregate quantity level, farm prices will be at least 15 percent below the average suggested by Brannan's formula.⁴

How will the income benefits from the Brannan proposals be distributed? Given our general values with reference to income equality, we would like to have the plan make incomes more equal than is now the case. At least this is the criterion I shall use—the plan should reduce the inequality in distribution of income. Three comparisons will be made: (1) within the Corn Belt; (2) between the Corn Belt and other agricultural areas; and (3) between the Corn Belt agriculture and non-agriculture. In general it does not seem that the subsidies will make the distribution of income more equal than it would otherwise be.

The Brannan proposals will have the same effect upon the distribution of income within agriculture as a price increase for farm products.⁵ If the Brannan program results in a 10 percent

⁴ The data on food consumption and relative food prices indicate a gradual yet perceptible decline in the demand for food at retail. With a decline in per capita consumption of about four percent, relative food prices have fallen since 1947. Part of this decline may be temporary, but it is unlikely that retail food prices will be as high in 1949 as they were in 1947. The demand for food from farmers has declined by more than the demand for food at retail. This is as one would expect. Marketing costs have been rising and are not expected to decline. Consequently all changes in food prices at retail will be reflected twice over at the farm level. The parity ratio was 106 for the first quarter of 1949—roughly the level indicated by Brannan's proposal.

We should also consider what has been happening on the food production and utilization side. In 1935-39, exports constituted 2.5 percent of the 1935-39 food utilization. In 1949 it is estimated that military (which includes food for American armed forces) and shipments and exports will require 12.3 percent of the 1935-39 food utilization. Making some allowance for U. S. armed forces personnel, a return to the prewar level of exports would permit about a seven percent per capita increase in consumption from a given level of production. If food production should rise to 140 percent of 1935-39, per capita food consumption could go as high as 118-120, even if exports are twice the 1935-39 quantity.

In any case, it is difficult to visualize a fall in relative food prices at retail of less than 10 percent (from 192 to 119-120) over the next few years. If this occurs, farm prices will fall by about 20 percent (from 262 to 210 if other prices remain constant) giving a parity ratio of roughly 85 percent.

⁵ We do not have empirical data that show exactly what happens to income distribution when only the prices of agricultural products change. Most pertinent data seem to be those showing the distribution of net money incomes of farm families in 1941 and 1947. A rough measure of changes in income distribution between the two periods is the percentage of families having two or more times the median income, and having half or less than the median income. In 1941, 21 percent had an income

increase in farm prices and farm price returns, the income distribution effects within agriculture will be equivalent to a 10 percent increase in farm prices in the market place. If production controls and marketing quotas are imposed upon individual farms in terms of historical bases, the above conclusions would not require substantial modification.

The above comments can be made more vivid by indicating in a rough way how the Brannan proposals would affect the distribution of income. This will be done by showing the final incidence of the subsidy by broad income or size groups of farms.

The following assumptions will be made:

1. Price returns are increased (by the proposals) by 10 percent on all products sold.
2. The distribution of income from sales of farm products is the same as reported by the Census for 1944, and the level of prices without the Brannan proposals would be those prevailing in 1944.
3. The Census classification of farms in Classes I to VII by size, degree of commercialization, and extent of dependence upon agriculture represents a meaningful classification of income groups.
4. Only part of the gross subsidy will be retained by the farmer actually receiving it. Prices paid for factors will be higher because of the subsidy. Class I farms will retain 45 percent; Class II and III, 50 percent; and Class IV and other classes, 55 percent.
5. There is no upper limit on the amount of production payments per farm.⁶

two or more times the median, while in 1947, 20 percent fell in this group. In 1941, 27 percent had half or less than the median income; in 1947, the percentage was 25 percent. (The medians were \$800 in 1941 and \$1963 in 1947). These data would seem to indicate that within agriculture, rising prices increased the incomes of income groups in about the same proportions. Since income earning opportunities off the farm improved, it is not unlikely that higher farm prices—nonfarm wages and job opportunities unchanged—would make the distribution of farm income relatively more unequal. The upper income groups receive a much greater absolute increase in real income than the lower income groups, of course.

Sources of data: *Statistical Abstract, 1947*, pp. 274, and Bureau of Census, Series P-60, No. 5, p. 16.

⁶ Laudable as the objective of fostering the family size farm may be, Secretary Brannan's proposal of limiting the benefit of his program to a total of 1,800 units is hardly workable. Since the price of some products would be maintained in the market-place—corn, wheat, and cotton—farmers specializing in these products would get the full benefit from the proposals. Brannan's proposals would discriminate against large-scale producers of perishable products as compared to the large-scale producers of durable products.

Table I indicates the effects of the proposals on net operator incomes in the Corn Belt. The net subsidy per farm operator on Class II farms—large family farms—is roughly 12 times what it

Source: Calculated from U S Census of Agriculture, *Special Report, 1945 Census of Agriculture*, Table 29

Given the greater proportion home consumption on small as compared to large farms, relative real incomes will probably be increased by the same or greater proportion on the large farms.

Table II shows the estimated average net operator subsidy for the U S and selected states. As one would anticipate, the states

Class II—Large-scale family commercial farms—generally with a value of products of \$8,000–\$19,999

Class III—Moderate-scale family commercial farms—generally with a value of products of \$3,000–\$7,999.

Class IV—Small-scale family commercial farms—generally with a value of products of \$1,200–\$2,999

Class VI—Family subsistence farms—farms with a value of products of \$500 to \$1,999, a value of land and buildings of less than \$8,000, and the farm operator working off the farm less than 100 days in 1944.

⁷ Farms in class II would not be affected by the upper limit referred to in the previous footnote.

with high incomes receive the most. Iowa farm operators dependent upon agriculture for their livelihood would receive more than four times as much as Mississippi farmers; California farmers would receive nine times as much. In general, the Corn Belt would receive much more per farm than the U. S. average.

Would the Brannan proposals reduce any "inequities" in the distribution of income between Corn Belt farm families and families not dependent upon agriculture? There is no evidence to indicate that the farm operator families in the Corn Belt that would receive the bulk of the benefits from the Brannan proposals have had smaller incomes than comparable non-farm families during the last several years.

TABLE III. AVERAGE FARM LABOR INCOME ON ALL FARMS AND SALES NUMBER AND POPULATION OF FARMS IN CLASSES I TO IV AS PERCENT OF THE TOTAL FOR CORN BELT STATES

	Average farm labor income, 1945 ^a	Sales of Classes I-IV as percent of total sales, 1944 ^b	Number of farms in Classes I-IV as percent of total, 1944 ^b	Farm population in Classes I-IV as percent of total, 1944 ^b

Ohio	1,270	94.9	56	61.6

^a Estimate made by author. Data estimate annual average labor income per worker on all farms, not just for farms in Classes I-IV.

^b *Census of agriculture, 1945, Special Report of 1945 Sample Census of Agriculture*, Table 29.

It seems that the Brannan proposals might well result in net farm incomes slightly in excess of the 1945 dollar level of \$16.9 billion implicit in the estimates in Table III.⁸ Farm marketings valued at \$26.2 billion dollars might result in a net agricultural income of \$16.5-17.0 billions, assuming the same level of production expenses as in 1948.⁹ Actually, production expenses would fall below

⁸ These estimates are based upon data given in *The Farm Income Situation*, July, 1946. The national estimates of income and expenses were later revised, but no new state estimates have been provided. On a national basis, the final realized net income from agriculture was \$16.3 billion dollars, or 0.6 billion dollars less than indicated above.

⁹ In 1950, Secretary Brannan estimates, the income support level would be roughly \$26.2 billion dollars. One might assume that if all prices were at the calculated support level, the cash value of farm marketings in 1950 would be \$26.2 billion dollars for a "normal" 1950 crop. But one would be in error in doing this. When

1948 because of the decline in feed and livestock costs implicit in the fall of the value of farm marketings.

As shown in Table I, the bulk of the subsidy will go to farmers in Classes I, II, and III. Assuming that roughly one-half of the gross income is required to meet production expenses, the net average family operator income of the Class III farms in 1944 was roughly \$2,200 to \$2,500, plus the value of the housing. This average income of the lowest of the three classes might be compared with the median family incomes of various non-farm groups in 1947. The median family income for rural non-farm families was \$2,800 in 1947. Families in towns and cities of 2,500 to 49,999 had median incomes of \$3,119.¹⁰ There do not seem to be any important differences between the real purchasing power of the incomes being compared.

If only labor income is compared, much the same result is apparent. In 1947, the average wage of employed industrial workers was about \$2,500. Table III gives the average labor income for *all labor on all farms* as well as certain other data on farms in Classes I to IV compared to the state as a whole. Even without making any adjustment for the low productivity of the farm labor on Class V, VI, and VII farms, the real income of farm labor in Iowa was in excess of employed industrial workers. It seems safe to assume a difference in purchasing power of 20 to 30 percent.¹¹ In Illinois, the case also seems to be fairly clearcut—the average real labor income on farms in Classes I to IV would be equal to or in excess of \$2,500 based on urban purchasing power.

Some further examination of the Ohio data is required: it is safe to assume that Classes I–IV will have 95 percent of the total labor income and probably not far wrong to assume that 70 percent of

farm production is rising, the quantity of marketings will be higher in any given year than in the previous 10 years, random fluctuations in output aside. For 1940–49, the average level of farm production for home consumption and sale was about 126. In 1947 this index stood at 137. If the index were 137 in 1950, the price supports implicit in Brannan's proposals, under the assumptions indicated in his speech of April 7, 1949 before the House and Senate Agriculture Committees, would result in cash receipts from farm marketings in excess of \$3.5 billion dollars. This is due to the fact that the Brannan proposals use the average level of marketings for the previous decade to arrive at the level of support prices.

¹¹ See Nathan Koffsky, "Farm and Urban Purchasing Power," in *Studies in Income and Wealth*, Vol. XI, (National Bureau of Economic Research, 1949), pp. 156–178.

the labor was employed on these farms.¹² This adjustment would give a net labor income somewhat in excess of \$1,700. On an urban purchasing power basis this is roughly \$2,100 to \$2,300. The Missouri and Indiana labor incomes on farms in Classes I to IV would be slightly higher.

There is a real question whether Class IV farms should be included in the calculations. In Ohio, for example, about 77 percent of the total subsidy would go to farms in Classes I, II, and III, while only 17 percent would go to Class IV farms. Yet Class IV farms are 81 percent as numerous as Classes I-III, and have 62 percent as many people living on them. If Class IV farms were eliminated from the calculation of labor incomes, casual observation indicates that the average labor income of the included groups would rise above \$2,500, measured in urban purchasing power.

The proposal that we have been analyzing cannot be considered as one furthering income equality in terms of its impacts upon the Corn Belt. Within the Corn Belt, the high income farmers would receive much more than the low income farmers. The relatively well-to-do Corn Belt would receive much more from the program than the poorer agricultural areas. And there is no evidence that the labor on the farms which would receive three-fourths or more of the total subsidy within each state have lower real incomes than individuals of comparable skills in other occupations under the economic circumstances implicit in Secretary Brannan's proposals.

Some comment on the functional distribution of income is in order. In the short run, one might anticipate that the broad factors of production—land, labor, and capital—would gain in roughly the same proportion and by perhaps slightly more than the increase in gross agricultural income. In the longer run, it seems likely that the least mobile factor (most inelastic supply) would gain the most. In the case of Corn Belt agriculture, this would be land. This will mean that a disproportionately large part of the subsidy would go to current owners of land. And I can think of no good reason why the present owners of land should be so aided.

Resource Effects

It was argued earlier that the Brannan proposals would result in

¹² The 1945 Census of Agriculture does not estimate labor use by value of product groups or by the Classes used here. Estimate for Ohio is a rough estimate based on data on population and cash wages paid and data for East North Central States from the 1940 Census of Agriculture.

support prices at least 10 percent—perhaps 20 percent—higher than the market prices would be. Presumably this would be true only for a time; in seven or eight years the formula should catch up. But will it? I don't believe so, if the Brannan program is carried out to guarantee 100 percent of the support standard. Not only will the formula not catch up, but in the process of "trying to catch up" it will result in a serious misuse of agricultural resources in the Corn Belt.

The most important relative agricultural prices in the Corn Belt are the feed-livestock ratios. Next most important are the ratios of one livestock product to another. This discussion will be limited to the former.

Secretary Brannan wishes to support the main feed grains, particularly corn, by the use of loans and purchase agreements. Assuming sufficient storage space is available, the support price for corn will thus change in response to only one factor—change in the index of prices paid.¹³ Changes in the demand for or supply of corn will not affect its market price and consequently cannot affect its price support level. This is hardly what one would expect in a formula that "will keep price relationships among commodities on a moving, up-to-date basis."

There is no easy answer to this basic dilemma of using supported prices in a formula to determine the level of future support prices. One might argue that production payments on corn is the answer. In one sense it is. If production payments were made on corn, stocks would not accumulate, but two other things would happen. The corn farmer would get the benefit of two subsidies on his corn, and the cost to the government would be very high indeed. If there were no storage program for corn, the price of corn (for an average crop) would reflect the support prices of the livestock prices. This would keep the market price of corn high and there would be only a gradual diminution in the support price for corn. Under the assumptions we have made, however, during the first decade or more of the program, corn producers would receive the benefit of the subsidy to livestock directly in the demand for corn, thus maintaining the market price of corn for insertion in the formula, and a subsidy to make up the (small) difference between the market price and the support price.

¹³ This is a slight understatement. If the quantity of farm products marketed is changing through time, the "multiplier" in the formula will be changed slightly.

I can but conclude that one of the worst features of the Brannan proposals is the method of calculating support prices. This method, when combined with the high level of supports, is completely unworkable if the criterion of economic efficiency is given any consideration. The formula used for calculating relative support prices is workable—and then only in a limited sense of the word—if the support prices are almost always below market prices. The above argument is in addition to any consideration of the effects of using price relationships for the past 10 years as a guide to future production.

The Corn Belt has achieved a relatively favorable resource position. There does not appear to be any considerable excess of resources. The Brannan proposal, if operated over a period of years, would only result in worsening the resource position. It would encourage resources to stay in agriculture which might otherwise find employment elsewhere. If a depression should come or the Brannan program fall into disrepute and be abandoned, the Corn Belt agriculture would find itself with excess resources that should have found employment elsewhere. Farm incomes would then be lower than would otherwise be the case.

The attraction of additional resources into Corn Belt agriculture could be avoided only by stringent production controls. If the production controls were really effective, then much of the income transfer to agriculture would result in higher land prices. A significant subsidy to the present land owners would occur. Is this a group warranting an income grant?

General Criticisms

Anyone familiar with the Corn Belt and the other prosperous areas of agriculture must seriously question the need for any scheme designed to maintain farm prices above "free" market levels during periods of high levels of employment in the economy. What objective does such a program achieve? It obviously worsens resource use by stemming the desirable resource adjustments that such areas as the Corn Belt are capable of making when resources are fully employed in the economy. *Do we, as a nation, wish to say that everyone employed in agriculture in 1949 is entitled to roughly the same real income as he earned from 1940 through 1949 and that he is to be permitted to earn that income in agriculture?* Unless we as a nation wish to restrict entry into agriculture, we will also try to

give anyone who wishes to engage in agriculture an economic opportunity of the same sort. In permitting entry, most of the income gains of those in agriculture when the program started would be dissipated, except in the case of land owners.

The most serious limitation of the program is its failure to tackle the problem of poverty. Despite the generally high level of incomes in the Corn Belt, there are tens of thousands of farm families with relatively meager incomes. Not only does a high level support price program fail to meet the needs of low income families, but the cost of the program is likely to be so great that it will preclude Congress' taking any action to meet the problems presented by low incomes in agriculture.

NOTES

RETAIL VALUE OF MEAT CONSUMPTION RELATIVE TO CONSUMERS' INCOMES AS A MEASURE OF DEMAND FOR MEAT

IN THE art of presenting economic facts, there is merit to devices that simplify complex subjects. A method for illustrating fluctuations in demand for meat has gained some acceptance in the field of livestock commodity analysis because it qualifies as a useful simplification of a difficult concept. The method requires only two statistical series—the calculated retail value of all meat consumed and disposable personal incomes. It is much more easily presented than multiple correlation analysis, to which it is akin. It admittedly has a weakness in that all subtleties in its construction and meaning are disregarded. However, this may not be such a harsh criticism, for if all methods of presentation having no deficiency were to be eliminated, economists would be crippled indeed in their task of generalizing in an understandable way on economic events.

Explanation of Method

The retail value of meat consumption is simply the product of the retail weight of consumption multiplied by the average retail price. It is first worked out for each of the four meats. Consumption of each meat by the civilian population is officially estimated by the United States Department of Agriculture. For the purpose here, it is expressed in per capita terms. It is also converted to a retail weight, by means of standard percentage factors which approximate the difference between retail weight and the carcass equivalent (wholesale) weight in which original consumption data are published. The average retail price of each meat is the estimated composite average price for all products as computed by the Bureau of Agricultural Economics from the retail prices by cuts reported monthly by the United States Bureau of Labor Statistics.

The retail value of meat consumption is an imputed valuation rather than a measure of consumers' expenditures for meat. Much meat is consumed at other than the urban retail prices reported by BLS. That consumed by institutions and the military services generally moves at less than a retail price. Hotels and restaurants also buy their meat at prices lower than retail, but their clientele in reality consumes meat at prices per pound that are far higher than

retail prices. The average price of meat bought by rural consumers may be somewhat different from the urban retail price. There are many additional examples of consumption of meat purchased at other than urban retail prices.

The disposable incomes of consumers is a series issued by the United States Department of Commerce. It relates to all personal incomes as corrected for immediate tax obligations. Incomes also are converted to per capita values.

Comparisons of retail value of meat with consumers' incomes have been made for annual data beginning 1913, and for quarterly data beginning 1947. Quarterly calculations employ a seasonal correction for all basic quarterly data—price and consumption of meats, and disposable income. Quarterly comparisons make possible a nearly up-to-date commentary on changes in demand for meat; their usefulness is believed to outweigh the possibility of more error due to the factored corrections for seasonal variations. Indexes of seasonality in consumption and price of meat are only approximate.

Current Results

During the interwar (1922–41) period, retail value of meat consumption averaged about 5.6 percent of disposable personal income. This percentage was exceeded somewhat in the early 1930's especially in the drought years, but in 1941 it dropped to 4.9 percent (Table I). Low prices for pork were the main factor in the low percentage of 1940–41. Comparisons of retail values for the war years have little meaning but the high percentages just after the war—6.3 in 1947 and 6.1 in 1948—testify to the high prices for meat in those years, even in relation to the record-high incomes of consumers. Quarterly data indicate that in the second quarter of 1948, the percentage rose to 6.5. But in the fall months of the year, prices of meats and of livestock fell rapidly. These price declines were greater than can be accounted for by the increase in production or by any seasonal factors. The percentage ratio of the value of meat consumption to incomes slipped to 5.6 percent in the fourth quarter of 1948. In the first quarter of 1949, when prices of meat gradually steadied, the percentage dropped off 0.2 points more, to 5.4. This is 10 percent below the index for the first quarter of 1948. Preliminary data indicate a small increase in the second quarter of this year.

TABLE I. RETAIL VALUE OF MEAT CONSUMED COMPARED WITH DISPOSABLE PERSONAL INCOME BY YEARS, 1925-48, BY QUARTER YEARS 1947-49

¹ Weighted average of retail prices for all important cuts.² Computed from estimated retail weight of each meat consumed per civilian consumer. Quarterly data seasonally adjusted, with quarterly indexes converted to an annual rate.³ Computed from income data of U. S. Dept. of Commerce 1929-49 Estimates for 1925-29 by Bureau of Agricultural Economics. Quarterly data seasonally adjusted.

As data for 1949 are a little below the 20-year average percentage, it might be said that demand for meat is "back to normal." Certain it is that the postwar premium prices have disappeared for meats as completely as for late-model "used" automobiles. Even though present prices of meat in cents per pound are still much higher than those before the war, these comparisons suggest that they are not far out of line with present supplies of meat and incomes of consumers.

Theoretical Significance

Unfortunately for economists, a comparison of retail value of meat with incomes has only limited forecasting value. It depends upon an extraneous factor—the size of consumers' incomes—which is itself hard to estimate. Moreover, percentage ratios to incomes have varied considerably about their average level in the past and may do so again. But in spite of these reservations, the method has a certain restraining function in forecasting, for it makes possible a matching of price forecasts against assumed levels of meat supply and of incomes, to show whether the forecasts imply a constant or a varying demand for meat. Furthermore, it can be extended to an evaluation of market prices of live animals, by use of average wholesale and retail margins, thereby completing a simultaneous examination of prices to farmers for livestock, retail prices of meat, and incomes of consumers.

The current "normal" relationship between value of meat consumption and personal incomes carries no certain assurance for prices of meat and livestock in the immediate future. But as it shows that the 1947-48 premium for meat is now gone, it inspires more confidence about future prices than did the high ratio of 6.5 in the spring of 1948.

A direct comparison of the retail value of meat consumption with consumers' disposable incomes is equivalent to a multiple-correlation analysis of the composite average retail price of meat on the quantity of meat consumed and disposable personal incomes. The corresponding analysis would have fixed lines of regression: that of price to quantity consumed would be curvilinear, with slopes such as would yield a constant value for all quantities of consumption (unit elasticity of demand); and that of price to consumers' incomes would be a straight line of a constant percentage ratio. That these are the built-in relationships is clear from the nature of

the value-and-incomes method. Any particular percentage ratio (e.g., 5.6) that may be considered average or normal carries with it the unexpressed assumptions that retail value would be the same for various sizes and composition of the meat supply, and that consumers as a group tend to allot nearly a constant percentage of their income to meats regardless of the aggregate size of that income.

Correlation analyses for the 1922-41 period result in a regression of retail meat prices on disposable personal income not greatly different from that implied in the retail-value methodology. The regression on meat consumption was somewhat inelastic. Thus their inherent assumption of unit elasticity may cause ratios of retail value to disposable personal income to tend slightly above average when supplies are scarce, and below average when supplies are abundant.

A comparison of retail values and incomes has the character of a regression analysis in another respect. Most regressions have some residual deviations, which are often explained away as caused by factors not included in the analysis. In the retail value comparisons, the deviations or departures from average ratios are brought to the fore and given emphasis. Thus we say that retail values were higher than average in 1948 but about average thus far in 1949. Neither the income device nor a correlation explains *why* prices and values of meat are sometimes high or low relative to incomes; each only brings out the fact of their departure from the average relationships.

HAROLD F. BREIMEYER

Bureau of Agricultural Economics

THE WORK OF THE PERMANENT AGRICULTURAL COMMITTEE OF THE INTERNATIONAL LABOUR OFFICE

PERSONS engaged in professional fields of agriculture, as well as farmers themselves, may be interested in a brief statement about the work of the Agricultural Service of the International Labour Office. The focus of attention on the United Nations and some of its new instrumentalities, such as the Food and Agriculture Organization, UNESCO, etc., has tended to obscure the fact that the I.L.O. is not only the oldest international mechanism with a continuous existence, but is still a vital one.

The International Labour Organization¹ was established in 1919, a product of the peace settlement after World War I. It is now one of the agencies of the United Nations. Its objective as phrased by the late John G. Winant, wartime ambassador to the Court of St. James and former director of the International Labour Office, is: "to secure social justice in the nations of the world. . . . In its conception it was based on the assumption that social justice is necessary if we are to look forward to universal peace. . . ."

"The approach of the I.L.O. has been to resolve problems rather than to engage in conflict, and its method is through conference, research, and cooperation."²

Although the I.L.O. in its very early period gave some attention to the problems of agricultural labor, its primary concern was with labor in industry. It was not until 1935 that the International Labour Conference approved the formation of a permanent agricultural committee. This committee was organized in 1937 and held its first session at Geneva in February, 1938.³ Following the usual pattern of I.L.O. committees, it consisted of representatives of governments, employers, and workers and so-called agricultural experts, along with representatives of international bodies dealing with social problems in agriculture, and certain members invited by the officers of the governing body to attend particular meetings.

The agenda of the first session, fixed by the Governing Body, consisted of the following items:

1. General discussion of problems of agricultural labor and their relative importance.
2. Protection of child labor in agriculture.
3. Holidays with pay in agriculture.
4. Technical study on hours of work in agriculture.

It was intended that another meeting of the committee would be held in Geneva in September of 1938, but the disturbances in Eur-

¹ The official name of the organization. The International Labour Office is the administrative organ of the International Labour Organization. The International Labour Conference is the highest authority and consists of national delegations, composed of two government members and one delegate each of management and labor. The Conference ordinarily meets once a year. The Governing Body functions as an executive council, meeting usually four times a year. It is elected by the Conference at three-year intervals and consists of thirty-two members.

² From a foreword to *What the International Labour Organization Means to America* edited by Spencer Miller, Jr. Columbia University Press, 1936.

³ The report of this session was published by the International Labour Office under the title, *Social Problems in Agriculture*.

rope made postponement necessary, and the outbreak of war prohibited further meetings until the second session was convened in Geneva in August, 1947. The agenda for this session consisted of the following items.

1. General survey of developments since the first session of the committee, and discussion of the order of priority for consideration by the committee of problems of agricultural labor.
2. Minimum wage regulation in agriculture.
3. The medical examination of children and young persons for fitness for employment in agriculture.
4. Security of employment and occupation in agriculture

A call went out from Geneva on March 15, 1949, to convene the third session of the committee in August or September of 1949. The agenda as approved by the Governing Body is as follows.

1. Hours of work in agriculture.
2. Medical examination of children and young persons for fitness for employment in agriculture.
3. Security of employment and occupation in agriculture.
4. Extension of Social Security to the agricultural population.

The reason some items recur in the agendas is that they were given only preliminary discussion in a previous session, and were brought up in subsequent sessions for final disposition. Some of the items may be retained for consideration in several sessions.

The I.L.O. seeks to implement its program through submitting to its member governments Draft Conventions regarding labor. If and when a member country ratifies such Conventions, it assumes the obligation to bring its legislation into line with the Convention's provisions. For example; a Convention which sets up standards for working conditions of women and young workers, when ratified by the member countries becomes, in effect, an international treaty on this problem. The general result is to provide uniform standards throughout the countries of the world and place them on a more nearly competitive basis, and, of course, to raise the level in countries whose standards previously were low.

The importance of attempting to do something in the field of agricultural labor throughout the world is underscored by the fact that upwards of two-thirds of the workers of the world are engaged

in agriculture. At the same time, the wide variation in agricultural conditions in various countries presents problems of almost insurmountable difficulty. This diversity was spotlighted in the 1947 session of the committee. The representative from the United Kingdom called attention to the fact that all of the standards being discussed had already been achieved in his country; while the representative from India could hardly conceive of their application in his country in the foreseeable future. Minimum wages, holidays with pay, the elimination of child labor, medical examinations for children entering agriculture, and the extension of social insurance to agricultural workers seemed to the Indian representative to be largely academic considerations. Even in the United States and Canada there will be much controversy over many of these measures, and it may be a long time before some of them are adopted, some may never become part of our systems. In short, some policies readily adaptable to certain countries are often not practicable in others. However, the general goal of improving the working conditions and the level of living of people who are engaged in agriculture is admittedly a worthy one, however difficult may be its attainment.

As the present representative from the United States on the Permanent Agriculture Committee, the writer has felt the need of some means of closer articulation between the committee and the agricultural people of the member countries. Obviously, any measures agreed upon for submission to the Governing Body and Conference, and perhaps ultimately submitted to the member nations, must have some practical relation to the conditions in those countries, and a basis in public opinion for their ultimate adoption. There is no way, at present, by which the committee members, themselves, can influence public opinion except through their limited personal efforts. Of course, no country is bound by its membership in I.L.O. to adopt any of the conventions that may be submitted to it, but it is bound by its agreement to have its treaty-making body consider such conventions. Three agricultural items will appear on the agenda of the thirty-third session of the International Labour Conference to be held in 1950. The Conference is the body which makes the final decision on Conventions to be adopted and submitted to the member countries. These items are: (1) General report on agricultural labor problems; (2) Minimum wage-fixing machinery in

agriculture; (3) Holidays with pay in agriculture. If either is adopted as a Convention by the Conference, it will come before the Senate of the United States for consideration. If the Senate should ratify it, appropriate legislation to implement it would be passed. Such is the procedure. Obviously, public opinion will determine the fate of such proposals.

One serious shortcoming in the composition of the Permanent Agricultural Committee at the present time, particularly as regards the United States and Canada, is that there is no representative of agricultural labor, nor of agricultural employers. Dr. John F. Booth of Canada, and myself from the United States, are the sole representatives. The fact that collective bargaining has never been a significant feature of agricultural employer-employee relations in these countries, and that neither labor nor employers are organized for this purpose, makes it extremely difficult to find authoritative spokesmen for either. Who is there, for example, to speak for the sharecropper, the migratory worker, the hired hand, or for the cotton planter, the cane grower, or the corn belt farmer?

Finally, it should be pointed out that very little research has been done in these countries on farmer-worker relationships. There is critical need for the study of attitudes of both groups regarding the adoption of uniform standards and for knowledge concerning the existing practices in various types of farming areas. It is impossible to consider intelligently the problems of agricultural labor without possessing a great deal more information than is available at the present time.

A final comment is in order. The Committee as presently constituted is a transitional one, composed of several of the original members (Booth and myself among them) and this forthcoming session will be the final one for it. A new committee will then be organized, which presumably will be more widely representative, both of member states and of economic groups. It is to be hoped that the problems of labor in American agriculture will be studied more intensely in the future, in order that we may have a more substantial base in factual information for the discussion of labor policy.

WHAT IS THE BASIS OF FARM FINANCIAL PROGRESS?

WHAT are the circumstances which make it possible for one farmer to accumulate a considerable estate during his farming life time while a neighboring farmer accumulates little? Is it because the one farmer started with more money, or because his farm is larger? Does it make any difference how deeply he had to go into debt when he bought his farm? Just what is the basis of farm financial progress?

A study of farms in Arland Township, Barron County, Wisconsin, made in 1939 and 1946 may hold some leads to the answers to these questions. Arland Township was chosen for the study of farm financial progress because it was representative of rural areas of the northern cut-over region of the Lake States. There was considerable delinquency in the repayment of farm mortgages in this area in 1939 and Federal Land Bank holdings were increasing. All the farmers of the township who could be located and interviewed, a total of 139 farmers, were visited. Interviewers asked about such things as tenure status, individual family history, current farm income, debts, savings, size of farm—anything that might throw light on the question of why one farmer made money and another did not. A repeat study was made of the same area in 1946.

Description of Area Studied

There are no villages or trading centers in Arland Township. A cheese factory, now closed, was situated across the highway on the west side of the township and several trading centers are within a 10-mile radius of its center.

Dairy cows supply the major part of the farm income in this area. The soil is fair to good for the production of feed crops. No cash crops are grown. The southeastern part of the township has some sandy soil while much of the remainder of the cropland is sandy to silt loam. A gently rolling topography characterizes the northeast and northwest corners of the area. Along the Hay River which flows directly south just west of the middle of the area is a fairly narrow strip of rough land.

The township was completely settled by the turn of the century. Records show that the last farm was homesteaded in 1899. At this time practically all farmers were owner-operators. Some farms

were operated by tenants soon thereafter, however, and by 1938, 20 percent of the farms were renter operated. Farm tenancy remained fairly constant from then to 1945 when 18 percent of the farms were operated by renters.

The time of purchase by the present (1938) owner-operators was fairly evenly distributed over the period from 1900 to 1938. (Table I)

TABLE I PRESENT OWNERS BOUGHT AT DIFFERENT TIMES

Year bought	Number of farms	Average crop acres	Net worth		Cost of farm when bought
			When farm was bought	In 1938	
1905	21	64	\$1,055	\$6,328	\$1,751
1906-1913	17	60	2,437	4,659	4,590
1914-1921	28	52	2,105	3,151	4,847
1922-1929	20	41	2,373	2,902	5,108
1930-1937	25	45	1,010	1,788	3,766
All Farms	111	52	\$1,759	\$3,681	\$4,025

The average net worths of the owner-operators at the time they bought their farms increased from \$1055 for the 21 farmers who bought their farms around 1900, to \$2373 for the 20 farmers who acquired farms in the eight-year period of the 'twenties. The group of 25 men who bought their farms during the depression period of the 'thirties were worth only \$1010 at the time they bought their farms. It also may be stated that whereas the initial net worths of the new owners doubled between 1900 and 1938, the average value of the farm purchased increased three times, and the mortgage assumed went up nearly four times. The owners who bought during the 'thirties were worth no more than those who bought in 1900 yet the cost of the farm bought had more than doubled.

Size of Farm Important Factor

These records showed a definite correlation between the size of the farm and the operator's financial success (Table II). As the size of the farm purchased increased, the net worth of the farmer at the end of 15 or 20 years increased both absolutely and relatively. For instance, as the size increased from an average of 29 crops acres to 89, the average net worth of the operator in 1938 increased from \$2394 to \$5995. This represents an increase in net worth of 75 percent for the group of smallest farms from the time the farms

were bought to 1938; and an increase of 166 percent for the 24 large farms over the same period.

TABLE II. RELATION OF SIZE OF FARM TO ACCUMULATED NET WORTH

Size of farm (crop acres) Range	Average	Number of farms	Net worth	
			When farm was bought	1938
0-39	29	41	\$1,865	\$2,394
40-69	52	44	1,907	3,567
70	89	26	2,258	5,995
All Farms	52	111	\$1,759	\$3,681

Additional evidence of the importance of the size of farm is shown in Table III. Farmers who bought the larger acreages of crop land had greater material accumulations in 1938 than the small farmers, whether they had small or large net worths at the time of purchase. The farmers in each of the net worth groups who bought the larger farms had greater net assets in 1938 than those who bought the smaller farms. There is no known reason, however, why relatively large initial net worths should be a handicap to accumulating assets over the years as might be inferred from the group of farmers with the largest initial net assets.

TABLE III. RELATION OF NET WORTH AT TIME FARMS WERE BOUGHT AND SIZE OF FARM BOUGHT TO ACCUMULATING ASSETS

Net worth when farm was bought		Number of farms	Net worth in 1938
Range	Average		
0 to \$999	\$ 346	41	\$3,106
16-39 crop acres		15	2,379
40-69 crop acres		18	2,743
70+ crop acres		8	5,420
\$1,000 to \$2,999	\$1,705	50	4,188
16-39 crop acres		21	2,717
40-69 crop acres		18	4,702
70+ crop acres		11	6,022
\$3,000+	\$5,234	20	\$3,669
16-39 crop acres		5	1,153
40-69 crop acres		9	2,970
70+ crop acres		6	6,696
All Farms	\$1,759	111	\$3,681

These tables clearly demonstrate the importance of the income-producing capacity of the farm as determined by its size. It would seem that if a farmer would be a financial success, his first consideration should be to buy a farm of sufficient size to support a large volume of business. Farm expenses usually do not increase as rapidly as income with the larger farm, and family size and living costs bear little relation to the number of crop acres on the farm. The size of the farm is important in accumulating assets because of the opportunity for greater current farm income.

The history of those operators who were renting farms was the same as for the owner-operators. In 1938 the six renters who had rented the largest farms had accumulated an average of \$2,557 in net assets, while the eight who rented the smallest farms showed an average of only \$759 net worth. The 14 farmers with the medium sized farms averaged \$1,321 net assets.

Management Ability Also Vital

Perhaps the second important factor in financial success is the managerial ability of the individual farmer. Even within each farm-size group the range in net cash incomes was large. The net cash income in 1938 of the small farm group varied from \$143 to \$915 for individual farmers. In the medium farm group it ranged from \$271 to \$1,028; in the large farm group, from \$332 to \$1,311; and those farmers with the largest debt load were not the same as those with the smallest net cash income. The range in the abilities of the farmers to organize and operate their farms very probably accounts for much of the variation within each farm-size group, because the productive capacities of soils were practically identical for the various groups of farms.

Large Initial Debt Not Prohibitive

Another of the factors which might conceivably influence the farmer's financial progress is the debt load he assumes when he buys his farm. There has been considerable speculation concerning the wisdom of the federal government policy during the past years of increasing farm ownership through 100 percent loans. Is that too heavy a load for a farmer to overcome?

Of course it is recognized that the 100 percent loans made during the past decade have much better chances of being paid off than if the loans had been made during times of more nearly normal price

relationships, but this study would seem to indicate that it is not unreasonable to expect farmers to pay out on 100 percent loans even during normal times. Such heavy loans of themselves need not represent insurmountable handicaps to owner-operators.

Nearly 21 percent, or 23 of the 111 owner-operators in 1938, assumed 100 percent loans on their farms at the time of purchase. The chronological distribution of the purchase of these farms was quite uniform over the period covered by this study so that a wide range of farm prices was represented. Only 40 percent of these farms were bought either from the parents or other relatives, in comparison with approximately one-third of all farms of the area. This indicates that most of these loans were not family affairs but strictly commercial loans, made with the expectation of being paid off.

The organization of these farms was not different from that of other farms of the area. Cropping systems were similar and both groups depended upon the dairy herd for the major portion of their income. Outside sources of income played a minor part in the income of both groups, and the volume of business for each group in 1938 was approximately the same. The farms bought were no larger than those bought by neighbors during the same time, and these farmers started with smaller net worths when they bought their farms. Yet the 23 farmers who started with 100 percent loans are making out as well as purchasers with large equities at the time of purchase. They had accumulated an average net worth in 1938 of \$3,742, as compared to an average of \$3,681 for the total group of 111 farms.

There is no source of information that would indicate what proportion of farmers with 100 percent loans dropped out before 1938. Neither is it possible to determine whether the survivors lived more "austerely" than did those with relatively smaller debt loads. But this study shows that those farmers still on farms in 1938 who started with 100 percent loans succeeded in saving as much from their current incomes as the other groups, and by 1938 had accumulated savings comparable to the others.

The question might be raised as to whether the absolute size of the debt load might not be more important than its relative size in influencing the accumulation of net assets. This would seem to have some validity. According to this study (Table IV) those farmers who had the smaller absolute debt load accumulated somewhat

more assets over the years than those with the larger debt loads even though the average size of farm for the different levels remained partly constant.

TABLE IV. RELATION OF AMOUNT OF DEBT AT TIME OF PURCHASE TO NET WORTH

Debt load		Crop acres	Number of farms	Net worth	
				When farm was bought	In 1938
	\$ 0	32	8	\$1,484	\$2,685
	0	50	8	2,915	4,388
	0	85	7	1,532	8,581
Average	0	53	23	\$1,975	\$4,937
1-1,500	885	22	11	948	2,373
	722	52	7	1,089	4,385
	922	82	4	2,176	4,691
Average	837	42	22	\$1,158	\$4,212
1,501-3,000	2,440	31	12	1,485	3,129
	2,267	49	10	1,245	4,092
	2,545	99	6	3,240	4,810
Average	\$2,401	52	28	\$1,775	\$3,833
3,001-4,500	3,867	35	7	2,605	838
	3,712	51	8	1,142	1,887
	3,625	86	4	1,557	3,557
Average	\$3,751	53	19	\$1,769	\$2,331
4,501-	4,995	35	2	175	2,390
	6,310	54	11	2,999	1,776
	6,793	87	6	2,336	3,979
Average	\$6,324	62	19	\$2,466	\$2,746
All Farms	\$2,496	52	111	\$1,759	\$3,681

As the debt load was increased from nothing to \$4,500, the accumulated net worth in 1938 decreased from \$4,900 to \$2,700. However, the increase in net worth with the smaller debt was not proportional to the difference between the debt loads. Another interesting observation was that the group of 19 farmers whose debt load was between \$3,000 and \$4,500 when they bought their farms had a smaller average net worth in 1938 than the group of 19 farmers with initial debts of more than \$4,500—the two groups averaging \$2,331 and \$2,746 in net worths respectively.

The debt load is not correlated with size of farm in this area. Both small and large farms were bought in each debt group. Accumulated net worths were greater within each debt group for those farmers who bought the larger farms. No matter whether the debt at the time of purchase was zero or \$6,000, the farmers who bought the larger farms accumulated from two to four times as many assets as those who bought the smaller farms. Larger debts apparently do not slow up the process of asset accumulation to any extent when associated with large enough farms.

Initial Assets Play Minor Part

Operators who start farming with greater net assets are presumed to have a better chance of making good than those who start out with less. This study would seem to indicate, however, that this time-honored assumption does not necessarily hold, i.e., that larger initial net worth of itself will account for greater assets 20 years later (Table III).

Twenty of the continuous owner-operators in the 1938 study had net worths in excess of \$3,000 at the time they bought their farms—their average was \$5,234. Twenty years later, their average net worth was \$3,669, a drop of 30 percent during the period.

Fifty operators entered farming with net worths between \$1,000 and \$2,999—average \$1,705. A generation later their net worths had increased to an average of \$4,188. This is not only \$500 more than the highest net worth group accumulated, but also represents an increase of 140 percent in net worth over the period.

Forty-one farmers averaged only \$346 net worth at the time they bought their farms. By 1938 they had accumulated only \$600 less than those who started with nearly \$5,000 more. They increased their holdings over the period by \$2,800, which is more than was accumulated by the group with \$1,350 greater initial assets. The group which was best off as far as initial assets are concerned actually decreased their net holding by \$1,600. This loss took place despite a few more acres of crops than were handled by either of the other groups.

These findings would seem to indicate that a farmer need not necessarily start with large savings in order to make money. On the other hand, it is possible that income from a 65-acre dairy farm is not large enough to maintain as large a net worth as some of these farmers possessed when they bought their farms. There is certainly

no logical reason why large net worth at the time of purchase of a farm should be a handicap to any farmer. Some farmers in each asset group accumulated considerably more than average while others accumulated much less. The cause-effect relationship here probably is size of farm and net assets.

Soil Productivity not Decisive Factor

The question is often raised in connection with the financial progress of farmers as to whether farms of the area with soils of better productive capacity cost more than other farms, and if so, does it pay to assume these additional costs. Practically every field in the township was classified according to its "present inherent productive capacity" by a soils specialist. Five levels of productivity were established: A, B, and C land, which under usual price conditions could well be kept under the plow; D land, questionable for profitable crop production; and E land, which a "combination of unfavorable circumstances" made unsatisfactory to continue to use for crop production.

This classification of the farms of the study shows that per acre crop production did tend to follow the inherent productivity ratings as made by the soils specialist, in that soils A, B and C produced definitely more than soils D and E. Operators on A and B soils in 1945 averaged only a few hundred dollars greater net worth than those on C soils, while the few farmers in the D and E groups had accumulated conspicuously smaller assets than any of the other soil groups. The difference was approximately \$2,400 in 1938.

This difference in net worth between the soil groups is enough to justify a somewhat larger payment for the higher rating farms, if all the difference is attributed to this one factor. It happens, however, that these lower rating farms also had 20 percent less crop land, and as we have seen the size of the farm is very important in accumulating net worth. Also such a conclusion assumes that the farms of each soil group received comparable handling—an unrealistic assumption. The writers found a few instances where the farmers on the D and E soils were hauling manure from the farms with the higher soil ratings and spreading it on their own farms. Some of the farmers on the less desirable soils made special efforts to improve yields that were not practiced by many of the farmers with the better soils.

1946 Study Shows Rapid Turn-over

It is surprising that only seven years after the first study—years of high prices and good farm incomes—only 71 of the 139 farmers visited in 1939 still lived on the same farms. Of the 68 farmers who had moved during this period, only one-fifth were accounted for by natural causes such as death and retirement. None of these farms was taken over by sons or sons-in-law. Nearly 40 percent of the changes were the result of foreclosures and voluntary sales by operating owners, while another 16 percent were renters who were forced to move because of the sale of the farms they were operating. By and large the noncontinuous operators were older, had less yearly income, and fewer net assets than the continuous owners. The fact that many of these farmers were nearing the 60 year mark and had fewer assets may help account for their failure to stay in the area. It also brings out the fact that a relatively large proportion of the farmers interviewed in 1939 were older men.

The accumulation of net assets of the 71 farmers still remaining on the same farms was nearly twice the amount accumulated during the previous 20 year period covered in the 1939 study. The for-

TABLE V. RELATION OF SIZE OF FARM WHEN BOUGHT TO NET WORTH IN 1945

Crop acres Range	Average	Number of farms	Net worth		
			When farm was bought	1938	1945
0-39	31	25	\$1,598	\$2,425	\$5,407
40-69	51	30	1,880	4,311	8,097
70+	99	16	2,749	6,444	9,570
All Farms	55	71	1,798	4,489	7,449

uitous gains resulting from the rapid increases in prices of farm products during this period thus completely overshadows the influence of the management factor which was more evident during times of more normal price relationships. It should be observed that although the farmers with the largest farms continued to increase their net worths during this period of rapidly rising prices, neither their absolute nor relative increase was as great as that of the smaller farms (Table V).

The total income of these larger farms was also much greater

than for the other two groups of farms. They spent relatively more money, however, so that savings during this period were not as large as for the owners of the medium sized farms. It is possible that the farmers with the larger net worths and larger farms did not have the incentive to save and pay off debts that apparently motivated the farmers with the smaller operating units.

A CALIFORNIA CASE STUDY IN LOCATION THEORY: THE GLOBE ARTICHOKE ON THE MORO COJO

The theoretical solution of a location problem for agricultural crops usually begins with the assumption of perfect competition between owners of land, of perfect knowledge of the market for all crops which may be grown on the land, and of perfect knowledge of the adaptability of various crops to the land. Given this simplified economic model, it is possible to examine the "technological" coefficients of production,¹ and thus to determine the use to which each piece of land will be put. This can be done without examining the motivations of owners of land or of entrepreneurs who may purchase the use of land. It is only necessary that there be a variation in the degree to which the profit-maximizing motive influences the actions of each individual.² But when the conditions of perfect competition are not satisfied, especially when there are only a few owners of land, it is no longer safe to neglect the motivation of the individual, and it is certainly not proper to assume that the landowner in his economic activities is dominated by profit-maximizing motives alone.³

Establishment of the present principal American center of globe-

¹ Production thought of as consisting of all those operations necessary to bring the crop to the ultimate consumer.

² The unnecessarily restrictive assumption is sometimes made that the dominant drive of entrepreneurs must be for maximum profits, e.g., J. M. Brewster and H. L. Parsons, "Can Prices Allocate Resources in American Agriculture?" This *Journal*, November 1946, pp. 938-60. But it is not necessary that the drive to profit maximization be either dominant or general to produce the usual equilibrium solution. If all other conditions of perfect competition are met, including that of unlimited entry, the firms with the lesser degree of profit-maximizing motive will be driven into bankruptcy by their more aggressive competitors. This will continue until only firms with the strongest profit-maximizing motivation survive.

³ Cf. M. W. Reder, "A Reconsideration of the Marginal Productivity Theory," *Journal of Political Economy*, October 1947, pp. 450-58, for a precise definition of profit-maximizing behavior, see T. de Scitovszky, "A Note on Profit Maximization and Its Implications," *Review of Economic Studies*, Winter 1943, pp. 57-60.

artichoke production in the lower end of the Salinas Valley in Central California is an excellent illustration of the part played in economic location by the motivations of the landowner. Artichokes require a climate with rare incidence of freezing temperatures, and, more significantly, one also free from excessive heat and excessive dryness. The Monterey Bay coast, which very seldom has frost and which is cool and foggy during most of the summer, appears to be well suited to the production of the artichoke. The artichoke's requirements are well satisfied by the silty clay loam and fine, sandy loam of the lower Salinas Valley flood plain.

It is not surprising, therefore, to find a crop with such special temperature requirements as the artichoke largely concentrated in this area. The process by which the artichoke found its way to its present principal location, however, does not reveal the smooth functioning of an automatic economic process, but rather the jerky change characteristically produced by a few individual decisions. Furthermore, examination of the way in which the solution of this particular location problem was reached suggests that there was nothing economically inevitable about the result, in the sense in which competition of many owners leads to an inevitable result. The overwhelming determinant was the personality of one strategically placed individual.

The greater part of the land in the Salinas Valley now devoted to artichoke production is contained in the 7,000 acres of the Rancho Bolsa del Potrero y Moro Cojo which the Mexican government granted to Captain J. B. R. Cooper of Boston in 1828. This rancho occupies the valley floor from the Pacific Ocean to a point about five miles inland. It includes almost all the valley land lying in the belt of heavy fog.

The rancho is still largely owned by descendants of the original grantee, and throughout its history much of its area has been under the control of one individual. Decisions as to land use have therefore been unique and personal, and there has been little opportunity for the play of competitive forces within its boundaries. Furthermore, the combination of soil and climate found on the rancho is almost unique, so that there is little basis for comparison with other property.

During the early years of its operation the lands of the Moro Cojo were devoted almost entirely to cattle raising. Probably in the 1860's Captain Cooper began to grow barley and wheat, and

this continued to be the major crop until 1888. In that year, Mr. Claus Spreckels constructed a beet-sugar factory at Watsonville which was the largest as well as one of the first in the United States. At the same time Mr. Spreckels signed the first lease in the Salinas Valley for sugar-beet land: 1,000 acres of the Moro Cojo at the mouth of the Salinas River. When the time came for renewal of this lease, the trustee of the estate, Cooper's son, insisted that Spreckels take the entire ranch. In this way the sugar company came to operate the property, with a short lapse of the lease on one section of it, until 1922.

The Spreckels Sugar Company subdivided the land into tenant holdings and constructed houses and farm buildings on each one of these subunits: these were then sublet to operating tenants who planted a substantial part of the land to sugar beets each year.

For over thirty years, from 1888 to 1922, the Cooper-Molera family which owned the ranch found the arrangement with the Spreckels company quite satisfactory. Rent was paid in advance, and the owners had no responsibility in the administration of their property other than cashing the rent check and paying the taxes. Negotiating a new lease every five years was something of an annoyance, but otherwise the arrangement seemed as good as could be asked for and the owners were content to let well enough alone. If additional income might have been obtained by more active supervision of the ranch, it was not thought to be worth the time and effort necessary to produce it.

In 1919 the death of Mrs. Molera, who had managed the property since the death of her brother, transferred control of over 3,000 acres of the property to her son, Mr. A. J. Molera. The personality of this new administrator had a profound and lasting influence on the utilization of the land placed under his control.⁴ Mr. Molera was not a farmer, and the practice of his family since the death of his grandfather had been to do little more than cash the rent checks. But somehow his interest in farming had been stimulated, and he began to take an active part in the affairs of the Moro Cojo

The Change to Artichokes

Through a friend who was raising artichokes in the Half Moon Bay area⁵ of San Mateo County he became interested in that crop.

⁴ The story of the conversion of the Moro Cojo from sugar beets to artichokes is based in large part on information supplied by Miss Frances J. Molera.

⁵ Some 50 miles north of the Moro Cojo.

The Moleras had already grown artichokes as a garden vegetable on the ranch they owned near Point Sur, south of Monterey, and Mr. Molera was convinced they could be raised on the Moro Cojo. The artichokes in San Mateo County were inadequately irrigated, but Mr. Molera reasoned that if he were to irrigate the excellent soil of his ranch, he should be able to grow large crops of the vegetable profitably.

Artichokes had been grown commercially in coastal districts of San Mateo County as early as 1900, but the acreage remained small and the market limited. Some artichokes were shipped to the eastern cities, but until World War I the principal supplier was France. When shipments from Europe stopped during the war demand for the western crop increased, and by 1921 plantings had been made as far south as Santa Cruz, and amounted to about 3,000 acres.⁶

In November 1921 the *Pacific Rural Press* reported⁷ that the New York produce firm of Steinhardt and Kelly had made arrangements with the San Francisco Artichoke Growers' Association to handle the crop from 5,000 additional acres, of which about 2,000 were to be along the Pajaro River near Watsonville.⁸ Steinhardt and Kelly were to distribute the entire production of the Association on the eastern seaboard. Shortly thereafter the produce firm launched a vigorous campaign to increase the demand for artichokes.⁹

A fifteen thousand dollar banquet was recently given by Steinhardt and Kelly of New York to competitors and customers who were fed artichokes and artichoke talk. This is something new in the way of selling a vegetable. The hosts at this banquet sent out the word that they can handle all the artichokes that they can get. The market is opening up in a conspicuous way and their representatives are now hunting new fields to produce this vegetable which has failed in all parts of America as a commercial crop except in the fog belt along the coast of San Mateo and Santa Cruz Counties.

Apparently the campaign of the artichoke dealers was successful and in July the *Pacific Rural Press* reported¹⁰ "Artichokes were handled through chain stores and in common groceries this season

⁶ E. A. Stokdyk, *Marketing Globe Artichokes*, Univ California Agr. Exp. Sta. Bul. 524, April 1932, p. 5.

⁷ Nov. 5, 1921, p. 462

⁸ The Pajaro River empties into Monterey Bay at a point about seven miles north of the mouth of the Salinas River

⁹ *Pacific Rural Press*, Jan 14, 1922, p. 55

¹⁰ July 1, 1922, p. 10

where heretofore they were handled only by the most exclusive trade."

Over 100 carloads were shipped into the New York market during the season at prices averaging \$8-\$10 per box up to April 1, and \$6 for the rest of the season.¹¹ Regular market quotations were not recorded until 1925, but from then until the end of the decade New York artichoke prices did not at any time rise to \$8 in the New York market, and typically fluctuated around \$4.¹² Prices were high in 1921.

The very attractive artichoke market, plus information obtained from the tenants, convinced Mr. Molera that the revenue from his property could be greatly increased by leasing directly to the farmers, rather than through the sugar company.

When the Spreckels lease expired in November 1921, there was a delay in renewal. Mr. Walter Tavernetti¹³ says that the Spreckels company offered to renew if the rent were cut from \$15 an acre, which they had been paying, to \$12.50 an acre. According to Miss Molera, her brother had found out that the tenants would be willing to pay \$35 an acre and more if he would drill wells on the property. The upshot of the matter was that the lease to Spreckels was not renewed, and Mr. Molera assumed direct supervision of the property and began leasing farms of from 75 to 150 acres directly to farmers, urging them to put in artichokes.

At first tenants were reluctant to invest the capital required for growing this perennial vegetable, which will bear heavily for three or four years, sometimes for as long as ten years, before replanting is necessary;¹⁴ it was not until Molera agreed to furnish the plants if the farmers would put them in that he began to make headway. The first planting was made in the spring of 1922, and by the fall of that year about 600 acres had been planted.¹⁵ By 1925 there were over 4,000 acres of artichokes in the county, mostly on the Moro Cojo.

Change under Large Landowner Differs

The foregoing account illustrates some of the characteristics of economic change to be expected if the decision as to land use is

¹¹ *Idem*.

made by one large landowner rather than by a number of small owners. Change under these conditions differs from change under competitive conditions in two principal ways: the general economic development is discontinuous and irregular; and the nature of the change is not determined by purely economic considerations.

The large landowner is free to some extent from economic pressure to adjust land utilization continually to changing conditions of the market if the income from the property is so large that any increase in income would appear not to justify the increased time and effort required to bring it about. For this reason there will be a strong tendency for property to be kept in its accustomed use over long periods of time. Thus the Molera family more or less left the Moro Cojo alone for over thirty years; this management policy was changed, not by economic forces, but by the accidents of birth and bequest.

On the other hand, when such an owner decides to change the way in which land is being used there may result a much more rapid conversion than would occur under competitive conditions. One decision only is necessary to bring about conversion of the total area included under one landownership; in addition the large landowner often has easier access to money-capital resources than the small owner simply because of the size of his land holdings. Molera's total investment in improvements on his land must have been considerable. Wells had to be drilled, the land leveled, and ditches dug. In addition, if he was to have better and more permanent farmers, it was necessary to build additional houses, barns, and sheds. Mr. Molera also undertook instruction of his tenants in cultivation of the new crop,¹⁶ and introduced those who needed financing at the local banks. The tenant's investment was not small, but the major burden of conversion had to be assumed by the owner.

Absence of noneconomic pressures may permit changes in land utilization to be largely a function of the personality of the landowner and consequently indeterminant in any social sense, furthermore, there is no guarantee that once change is decided upon the new use to which the land is put will be the optimum use.¹⁷ We cannot be sure, for example, that concentration on artichokes was the

¹⁶ There was very little information in this country on growing of the artichoke. Mr. Molera used as his principal guide a French publication which he had seen advertised in a Spanish farm journal to which he had subscribed. Later the great horticulturist Luther Burbank advised him in the culture of the crop and in the selection of varieties.

¹⁷ If the landlord's decision to change does not arise from a desire to maximize returns the new use of the land may even produce a smaller revenue than the old use

best choice even when the change was first made; we certainly have no firm assurance that it is now the best choice.

Even under "competitive" conditions the problem of testing efficiency of land use is by no means an easy one, but the presumption would seem to be that there is a general tendency for owners who employ land in less efficient uses to be forced to surrender their land to more efficient owners. When the landownership unit is very large, lack of homogeneity of land over very large areas makes it extremely difficult for potential purchasers of the land to make accurate comparisons of the income from the land in its present employment and its possible income under alternative employment.

As far as the economist is concerned the solution under such circumstances must be indeterminate within wide ranges. The lower limit of efficiency is that which will result in the rapid using-up of the capital value of the land; the upper limit of course is the optimum land use available. Within these very wide limits the solution of the land-use problem, when large ownership units are present, is determined by chance as it operates to put control of the property into the hands of a more or less efficient and profit-minded owner

THE EFFECT OF A REDUCTION IN FARM PRICES ON FARM EARNINGS

OF MAJOR concern to farmers at all times is the trend and the level of agricultural prices. The level of farm prices is one of the most important factors affecting the year to year variations in income received by the farmer. The trend of farm prices (whether up or down) affects the prospects of future earnings. Farm incomes are highly unstable and fluctuate widely from year to year.

Most farm products are sold in a highly competitive market with demand and supply relationships determining the prices received.

The volume of production of individual farm products (especially crops) is subject to considerable variation from year to year, contributing further to fluctuations in the prices of farm products.

On the other hand, prices of things bought by farmers tend to be more rigid. An important factor contributing to the rigidity of these prices is the relative inflexibility of wage rates in industry. In gen-

eral, wage rates rise and fall less than prices and are not adjusted as quickly to changes in demand and supply. This rigidity in wage rates is more pronounced during a period of declining prices. When demand declines for industrial products, workers are laid off and output is reduced. This adjustment of production of most manufactured products to fit the demand helps maintain prices of manufactured products at a fairly stable level. Cash farm production costs then (being largely payments for manufactured products and hired labor) tend also to be rigid. Consequently, when the selling prices of agricultural products decline, net farm income declines even more.

This pressure on net farm income during a price decline is likely to be more intense in the future because of two important changes with respect to farm production costs which have taken place in the last two decades. First, the level of farm costs has risen markedly in the last few years. Farm production costs today are the highest in history. Many farmers now have cash farm expenses higher than their total gross income in previous years. Farm costs for 1948 totaled approximately 18 million dollars which was greater than gross farm income for any year prior to 1942.¹ Second, direct cash expenses now make up a much higher proportion of total farm costs than they formerly did.

Following World War I, many farm costs were not direct cash outlays. Horses furnished most of the power and could be raised on the farm. When prices declined, it was necessary for farmers to accept less than going rates for their labor, thus absorbing part of the price decline in a lower standard of living.

Since then, great strides in farm mechanization have taken place, resulting in a much higher proportion of direct cash outlays. Cash outlays for gas, oil, and repairs are necessary for modern power equipment farming. Mechanization has required a higher investment in farm machinery, the cost of which must be paid out of farm earnings. The improved farm practices widely adopted in the last few years, although highly desirable, have increased total farm costs. Items such as improved varieties of seed, chemical weed control, and the wider use of commercial fertilizers, all are direct cash production costs. The effect of these two changes in the farm cost picture, a higher level of total farm costs and a greater proportion of direct cash expenses, are problems about which farmers are seriously concerned when farm prices decline.

¹ *Agricultural Situation*, BAE, Vol 82, No 11, Nov. 1948.

In order to illustrate more specifically the effect of a decline in farm prices on farm earnings, a comparison has been made between the actual 1948 earnings and the probable earnings, assuming farm prices at 90% of parity (Table I). These figures represent the average receipts, expenses, and net farm income for a group of ten farms in southeastern Minnesota and also similar data for a group of five farms in southwestern Minnesota. These farms were selected from the records of cooperators in the southern Minnesota Farm Management Services. The farms selected in both these areas are larger and more productive than the average for the area. They are more highly mechanized. Major sources of income for the group of farmers in southeastern Minnesota was from the sales of dairy products, hogs, and poultry. For southwestern Minnesota sales of beef cattle and hogs provide the major sources of income. It is emphasized that this illustration is not a forecast that prices will fall to support levels nor is it to be considered as an endorsement of a specific price policy for agriculture. The purpose of Table I is merely to show the general effect on farm earnings of a reduction in farm prices and to supply a guide to farmers analyzing their own records. Farmers, then, must make their own interpretations as to the rate and extent of any future price changes in analyzing the effect on their own earnings.

The average net income received by these ten dairy, hog, and poultry farmers in southeastern Minnesota in 1948 was \$10,404 (Table I). Assuming that prices were at 90 percent of parity with the same output as in 1948, their net income would then average \$7,921. This represents a decline of 24 percent in net farm income, showing the effect in the immediate future of a reduction in farm prices. Receipts for this group of farmers would decline about 17 percent, while costs would decline only 6 percent.

The decline in farm earnings was considerably greater for farms with feeder cattle and hogs in Southwestern Minnesota. For this group, the average net farm income in 1948 was \$6,384. Assuming prices at 90 percent of parity again, their net income then would average only \$2,352, a decline of 63 percent. The wide difference in the effect on earnings of these two different types of farms of a decline in prices to 90 percent of parity is accounted for largely because of differences in the ratios of present prices of various farm products to their corresponding 90 percent of parity figure. Average

¹ Parity prices as given in *Agricultural Prices* (Monthly), BAE, 1948.² Assuming the same output as in 1948.³ Cost of livestock purchased adjusted downward in same ratio as estimated decline in selling prices of livestock.⁴ Miscellaneous crop expense reduced five percent.⁵ Cost of feed grains purchased adjusted downward to correspond with selling prices. Commercial feeds purchased reduced 10 percent.

prices received for beef cattle and flax in 1948 were much higher relative to parity than were the prices received for dairy products. An adjustment in prices to 90 percent of parity then would cause a much higher percentage reduction in income for farmers whose major source of income is feeder cattle than for those farmers selling dairy products.

Since these calculations were made to show the immediate effect, only those costs which would be reduced in a short time were adjusted downward. These include cost of purchased livestock, miscellaneous crop expenses (cost of seeds and fertilizer) and feed bought. If the trend in farm prices should continue downward for an extended period of time, some of the other costs (which are not adjusted in Table I) would also decline. Also, certain farm costs, such as the purchase of new equipment or the erection of new farm buildings, could be postponed. Certain production costs, however, are likely to remain high for a considerable period of time. Property taxes may even continue to rise when farm prices are falling. Interest and payments on indebtedness are fixed cash payments that do not fluctuate with the price level. Costs of labor and custom work hired are expected to remain high for some time.

This lag in cost rates when prices received by farmers are on the down turn places farmers in a price-cost squeeze, depressing farm incomes even more on a percentage basis than the decline in farm prices. Farmers thus need to concentrate to a greater extent on cost control to produce products as efficiently as possible. The emphasis must be placed upon increasing the output per worker and reducing costs per unit of product.

While farmers today are generally in a stronger financial position than at any time previously, some farmers who have gone heavily into debt in the purchase of land and equipment or in the erection of new farm buildings, will be in a vulnerable position if farm prices decline rapidly. Paying off indebtedness now and the building up of reserves from current income will strengthen the farmer's position in meeting the pressure on net farm income during periods of adverse economic conditions.

SYNTHESIS OF LABOR INPUTS FOR HOGS FROM TIME-STUDY DATA*

FOR all kinds of farm planning it is necessary to develop sets of input and output data relating to costs, yields, prices, labor requirements and the like. While these are physical items, agricultural economists have considered it necessary to devote a considerable amount of effort to the collection of such data. Economists find it advisable to do this work themselves instead of getting the information from physical scientists because they want to find out "—what technical rates are possible in practice and which the farmer expects"¹ rather than the results of controlled laboratory experiments.

Various sources are used in the development of these "technical rates." For individual farm planning, a farm account book summary may be the principal source. In farm budgeting for research or extension purposes, account books, survey data, and experimental results are used. The search for input and output data represents a considerable share of total expenditures for farm management research. The possibility that too much effort is used up in this way has been raised by Dr. Schultz in the article previously cited, and by others. There is also need for improvement in the quality of input-output data.

The purpose of this paper is to describe a method of synthesizing one type of budget input data—labor requirements—from information secured in a time-and-motion study. The method is applied to the development, for the hog enterprise, of labor inputs that are suitable for arriving at comparative production costs on farms of different sizes. For this purpose, input data must be obtained with a considerable amount of care.

These labor inputs might be taken from survey data, but examination of published labor input figures based upon farm surveys indicates that, although they may be suitable as an expression of average labor requirements in a given area, they would be of limited usefulness in a study of relationships between size of enterprise and costs. The amount of labor reported for small enterprises may be high because of an abundant supply of labor, if labor is substituted

* Prof. L. S. Hardin, Purdue University, made available unpublished materials for use in this analysis.

¹ Schultz, T. W. "Theory of the Firm and Farm Management Research." *This Journal*, p. 584, August, 1939.

for some of the equipment. Thus hand-feeding may take the place of self-feeders, and water may be carried in pails rather than supplied by an automatic fountain. Methods of production may not be the same; some farmers farrow two litters a year, others only one. Results obtained from enterprises of different sizes are likely to vary because of differences in skill of the farm operators. Because of all these variations between individual farms it is difficult to determine whether reported differences in labor requirements are due to size of enterprise or to technique.²

A survey designed to compare efficiency in use of labor on enterprises of different sizes would have to include a very large number of records in order to permit the sorting and subsorting needed to give reasonable homogeneity in the characteristics of farms in different size-classes. Otherwise, the fundamental assumption that observed variations are a result of differences in scale, and not in system, of production is violated.

Because of these limitations on usefulness of survey data, an attempt has been made to calculate labor requirements for hog enterprises of different sizes by synthesizing information from a detailed time and motion study of individual jobs. In this process, the assumed system of production is kept the same, and variations due to differences in skill and dexterity of individual operators are eliminated.

Basic data are taken from an Indiana study of the hog enterprise.³ This study contains detailed time and motion analyses of the principal jobs in hog production as observed on five Indiana farms. While production practices, methods and equipment were not identical on all farms, data were presented in a way to show in detail the processes used performing each job and time spent on each operation, as recorded in stop-watch studies.

The procedure involved in synthesizing labor inputs from these data was as follows: First, certain assumptions were made as to the system of hog production, production practices, and equipment. The average distance traveled from the farmstead to the hog pasture was assumed to be 40 rods. It was assumed that an average of

² For examples of survey data on labor requirements by size of hog enterprise see: J. A. Hopkins, "An Economic Study of the Hog Enterprise." *Iowa Agr. Exp. Sta. Bul.* 294, 1932; and H. C. M. Case and R. C. Ross, "The Place of Hog Production in Corn Belt Farming." *Ill. Agr. Expt. Sta. Bul.* 301, 1927.

³ Oberholtzer, John W., *The Application of Motion and Time Study Techniques to Certain Agricultural Enterprises*. Purdue University, June, 1944. Unpublished Thesis.

6.1 pigs were saved, and 5.7 raised per litter, and that pigs were sold at 235 pounds and sows at 335 pounds. It was assumed one boar would be kept for each 30 sows and that a boar would be maintained if there were as many as five sows. Based upon a number of publications on hog production, a list of jobs connected with the enterprise was developed, and for each job a process was outlined. These jobs and processes are shown in Table I. For most of these processes, it was possible to adapt data from process charts in the Indiana study for the approximate total time required for each step of the process. One of these process charts is shown as Table I. This illustrates the kind of detailed measurements on which estimates in Table I were based. From the nature of each process, a decision was made as to the degree to which labor time would vary with changes in number of hogs. Time spent in travel, in starting tractors, or opening gates, was generally considered as fixed. A few operations were considered to be semi-fixed, such as hauling loads of water or feed, where time would not vary by individual sows, but by groups. Operations that primarily involved work with the hogs were considered to require a constant amount of time per hog.

With information given in Table I it is possible to construct a series of estimates, by jobs, of time requirements for different numbers of hogs, assuming no change in production practices, as shown in Table III. A question may be raised as to practicability of assuming the same practices for large and small numbers of sows. Consideration of the jobs to be done and the processes followed indicates that the system assumed fits both cases fairly well. Perhaps more allowance should be made for greater distances traveled with larger numbers, and in a few instances a producer of a small number of hogs might find it advisable to do more hand carrying of feed and water, but these are minor deviations.

Total hours per sow computed in this manner is somewhat lower than is usually reported in farm surveys. According to Dr. Oberholtzer, much of the difference between time required for an operation according to a stop-watch study and a survey can be explained as follows. "In the stop-watch studies only the time spent in actual labor or in necessary delays was recorded. The surveys tend to include time spent with the hogs when the operator was not working and when his presence was not necessary."⁴

While computed time spent on hogs is usually lower, variations

TABLE I JOB ANALYSIS OF THE HOG ENTERPRISE, WITH APPROXIMATE TIME REQUIRED PER 20 SOWS^a

Job	Process	Minutes per 20 sows		
		Total	Fixed	Vari- able
Spring Farrowing (21 days)				
Move houses 40 rods to pasture	Move with tractor, 2 houses per trip			
Clean and bed	Spray interiors of houses. Haul straw from stack and bed houses.	1,048	98	950
Move sows into houses	Haul in low wagon, tractor drawn.	440	44	396
Care during farrowing	Four daily trips to farrowing pens on foot.	736	420	316
Hauling feed	One load (about 30 bu) hauled per ten sows during farrowing period	74	18 ^b	56
Hauling water with 800 gal. tank wagon. (Assuming 3 gal per sow, four trips will take care of 20 sows for entire period)	Fill water wagon while doing other chores. Start tractor, drive 200 ft to wagon, hitch and drive 40 rods to field, open gate, drive through and close. Drive 100 ft to farrowing quarters and insert hose. Fill fountain while watering at quarters, remove hose, return to well, unhitch and return to tractor	60	—	60
Feeding and watering; twice daily	Walk to farrowing quarters, feed and water sows (feed and water available at quarters), return from farrowing quarters	534	210	324
Spring Suckling (42 days)				
Clean and bed houses	Clean houses and haul straw as above	740	60	680
Castrate	Pen sows in farrowing pens and pigs in farrowing houses. Catch pigs, lay on wall of house and castrate. Put pigs in pens with sows.	225	5	220
Vaccinate	Handle pigs in same manner as above.	225	5	220
Wean	Build creep around self-feeder (3 feeders for 20 sows)	44	17	27
Feed and water	Feed ear corn to sows twice daily, pigs fed in self-feeders in creep.	3,515	2,189 ^b	1,326
Summer Feeding (140 days)				
Sort for market	Set up pens, drive into pens	636	127	509
Haul feed 40 rods and fill feeders	One load corn (2,000#) every every other day for 120 pigs.	2,590	—	2,590
Water	Haul with tank wagon to 100 gallon fountain waterers in field. One trip every other day for 120 pigs.	2,128	700 ^b	1,428
Summer Feeding, sows (60 days)

in labor input with changes in size of enterprise correspond fairly closely to survey results for small and medium sized herds. The synthesized data show a smaller decline in labor requirements than survey data, when medium and large herds are compared.

Experience gained in working through this synthesis of time-study data permits the following conclusions to be advanced with respect to usefulness of the approach as a source of budgeting information: (1) Synthesizing of input data requires intimate knowledge of the processes and operations involved in an enterprise. Some of this may be gained in making the time-study, but if the purpose is to set up typical budgets for an area, a survey is needed to show the typical situation with respect to equipment and practices. (2) Analyzing an enterprise in terms of jobs and processes facilitates the explanation of labor savings associated with volume of business. (3) Stop-watch studies tend to show minimum requirements. The person studied, knowing he is being watched, probably devotes his attention more strictly to the job at hand than he usually would. He may also move at a smarter pace than is customary. Time and motion studies omit or minimize time spent by farmers in looking over their crops and livestock, speculating on alternative lines of action, and making decisions. However, it should be relatively easy to develop a correction factor by comparing survey and time-study results on identical farms. (4) Time study data permit development of input requirements for a specific set of conditions, while survey data usually conceal wide differences in size of enterprise, equipment and practices used, and soil and weather conditions. (5) Where time-study data are available, labor inputs can be synthesized at low cost.

Bureau of Agricultural Economics

HIGH FARM INCOME AND EFFICIENT RESOURCE USE

WILL prosperous conditions in agriculture, if achieved by government programs, keep excessive numbers of people and other resources in agriculture? Orthodox economic analysis leads most farm economists and farm leaders to say yes. They conclude that if a farm program were successful in keeping farm income at a higher level than free market prices, one of the important un-

desirable results would be too many people and too many other resources in farming—inefficient resource use. They hold this up as one of the great social and economic dangers of government programs for agriculture.

But a broader and more thorough analysis of forces at work in determining resource use in agriculture throws grave doubts on the accuracy of the orthodox answer. More people are born on farms every year than can find permanent jobs in agriculture. There is also a large fund of improved technology not yet adopted by farmers. These are two of the basic considerations in efficient resource use in agriculture.

Assuming jobs are available outside agriculture, will excess farm people move out faster under relatively high or relatively low prices for farm products? The first answer is that low prices will drive them out faster, but when one looks at historical trends one finds it is the areas where family incomes have been highest that farm consolidation, farm mechanization and city migration has been the most rapid. Between 1930 and 1940 farm population declined one percent in Iowa and increased 3.5 percent in South Carolina and 7.3 percent in Tennessee. Children in higher income families receive more school and college training and have more assistance in migrating to new jobs than children in low income families. In the past at least, and this has been true in the post-war years, farming at its most prosperous levels has been less desirable than many other occupations. There has been a reduction in the working force and a rapid increase in size of farms in the immediate post-war years. Farm prices have been above parity but the evidence does not support the orthodox answer that high incomes hold more people in agriculture.

Again in the field of technology the most significant observation is that high prices speed up the adoption of improved technology and low prices slow down the rate of adoption. It is true that more machinery, more fertilizer, more insecticides and other materials will be used in agriculture at a high level of farm income than at a low level of income, but farm consolidation will be speeded up and most family farms are now too small to use new machinery most effectively. Farm families will be released from agriculture by the adoption of improved technology, and members of farm families will be released from farm work at earlier ages to attend colleges

and vocational schools or to find non-farm jobs as more machinery and equipment is purchased with the higher incomes.

Proposals to maintain farm income at higher than free market price levels should be questioned from the standpoint of the controls and regulations which may be associated with them. They may lead to a transfer of income from non-farm to farm people that cannot be justified by socially acceptable criteria. There may be other reasons for disapproving of such proposals such as the growth of "big government"; but there is little basis for the fear that they will keep excess people in agriculture.

BOOK REVIEWS

Rural Life in the United States. Carl C. Taylor, Arthur F. Raper, Douglas Ensminger, Margaret Jarman Hagood, T. Wilson Longmore, Walter C. McKain, Jr., Louis J. Ducoff, Edgar A. Schuler. New York: Alfred A. Knopf, Inc., 1949. Pp. xviii, 549. \$5.00.

This book is a contribution from the past and present staff of the Division of Farm Population and Rural Life of the Bureau of Agricultural Economics of the U. S. Department of Agriculture. It is a mine of information made possible by the collaboration of specialists. It is organized into five parts:

- I. Rural Society and Rural Sociology
- II. Rural Organization
- III. Rural People
- IV. Rural Regions
- V. Farmers in a Changing World

Rural sociology has, in fact, been farm sociology and this book follows the traditional pattern. The entire community is covered in discussing occupations and in considering conditions common for all in the community such as schools and facilities for medical care. The book is addressed primarily to rural sociologists, yet agricultural economists will get much from it. Many sections, especially those relating to population and labor force, provide important reference material for agricultural economists. For the most part the discussion avoids promotion. A notable exception is chapter 6, "The Rural School and Education," where the opening sentence, "the plight of the rural school," serves as the theme.

There are some omissions, cursory treatments and orientation of materials that detract somewhat from the over-all usefulness of the book. Some of these may have arisen because of agency bias or attitudes that come from professional specialization, but others do not so readily suggest such explanation. Such matters as the alleged domination (at least in some states) of the Agricultural Extension Service, by one or another of the powerful farm organizations; and duplication in counties among numerous agencies of the U. S. Department of Agriculture, for example, are omitted. Furthermore, the data as to equality of income selected for presentation are those that lend maximum support to the theme that farmers are a disadvantaged group. On p. 298 is a chart that shows per capita

income of nonfarm people close to three times that of farm. Yet a national survey for the year 1941 (see U. S. Dept. Agr. Misc. Pub. 520 and U. S. Dept. of Labor, Bul. 822) reports the following per capita incomes for families of two or more:

<i>Group</i>	<i>Per capita income</i>	<i>Farm income equals 100</i>
Farm operator	\$409	100
Rural nonfarm including farm laborer	447	109
Urban	828	202

For these data nonmoney income in the form of food from the farm and garden is valued on the basis of prices that probably would have been paid had it been purchased. If farm laborers had been included with the farm rather than the rural nonfarm group the difference would have been increased somewhat, but even so quite different contrasts would have resulted from those used in the book. Furthermore, in discussing inequality of income, disparity between farm and nonfarm people is featured much more than that within agriculture. Little is said of the pressure that led to the shrinkage of the program of the Farm Security Administration designed to assist low-income farm families.

Juvenile delinquency is omitted in spite of the fact that a national conference was held in 1948 for which a separate report was prepared for farm communities. The discussion of "prospective development" of social security seemed less forthright than would be desirable if an understanding is to be developed of the forces operating on various legislation programs. In the final paragraph is a sentence referring to the "social conservatism of politically influential farm groups." The next sentence tells us, however, that rural public welfare is expected to lag behind urban public welfare because of the inadequate tax base.

More and more as attempts are made to use social sciences for predictive purposes it is recognized that the findings of various subject matter fields such as characterize college curricula should be synthesized. The various subject matter fields have too often gone their separate ways. Agricultural economists would be helped if sociologists (to whom has largely been left the investigation of population, at least in the United States) could tell them more about the nature of the decisions that underlie labor mobility. What, for example, is the income differential necessary to induce moves either in place of residence or occupation? What is the relation of the differential to distance? It would be helpful to know who is shifting

from nonfarm to farm place of residence and under what circumstances. Information beyond that on page 240 is needed. It would be important to know if those arriving on farms from nonfarm areas are coming for the most part to the fringe farm population. Perhaps with a different definition of terms they would be looked upon as merely moving from one nonfarm location to another.

Rural sociologists are also limited by the shortcomings of the economic data available and their analysis. Over and over again welfare implications of farm-nonfarm comparisons are invalidated because of lack of measures of differences in the cost of living. Some confusion is also introduced by erroneous interpretation of consumption data. The high cost of medical care at low income levels, for example, is overemphasized. The survey for any year may be heavily weighted with those who are much below their long-run income position because of the illness of the main earner. In other words the cost of sickness is high at the low income level because sickness that brought high doctor bills perhaps also brought the low income.

To make more meaningful the great mass of detail the book presents, more attention should be given to hypotheses and their testing. Focusing on certain current situations would have much merit. For example, it seems highly desirable at the present time for rural sociologists to throw light on the reaction of rural people to administrative arrangements implicit in proposed or actual legislation directly affecting them. Some social scientists fear concentration on practical issues on the grounds that advance comes from pure science. It seems highly probable, however, that advance comes from striving to answer questions urgent enough to give impetus to creative efforts. Such selection does not preclude rigorous analysis.

MARGARET G. REID

University of Illinois

Major Economic Forces Affecting Agriculture with Particular Reference to California, S. V. Ciriacy-Wantrup, Hilgardia, Berkeley; University of California, 1947. Pp. 76. Contribution from the Giannini Foundation of Agricultural Economics.

Californians who hold that the economy of that state is essentially a thing apart from the economy of the remainder of the country, will find Professor Wantrup's volume most enlightening. Agricultural economists who have been reading or writing on the subject

of trends and fluctuations in farm production, prices, income and costs and the relation of various categories of national income to farm prices and income will find much of the first half of this volume a familiar story. Students of international trade and finance will probably not be too pleased with the brief treatment of and minimized role ascribed to foreign trade and its relations to United States agriculture.

Those who look to monetary and fiscal gods alone to lead us from the business cycle wilderness will find little cheer in Wantrup's thesis. On the other hand, those who have discovered order and logic in the Keynesian slant on economic theory and policy will be at home in the solid second portion of *The Major Economic Forces Affecting Agriculture*.

Aside from the greater rate of expansion of California's agriculture, especially during 1910-30, the fluctuations in the substantive economic aspects of agriculture were shown to follow a closely similar pattern for California and for the United States.

Series of data (arithmetic averages) and related descriptive material covering for the most part the period 1910-1947 include farm employment, commodity prices and production, farm income, and major farm production expense categories. The major concern of this study is with the demand side of the farm price and income equation. As an introduction to demand analysis, the familiar relationships between non-farm national income and income of industrial workers to farm prices is stressed. The author properly points out, however, that those relationships are merely the immediate or first line manifestations of more basic economic forces which ultimately determine the level and fluctuations of farm prices.

Foreign trade in farm products is placed far down the scale of importance among the economic forces affecting agriculture. The relative size of domestic and foreign markets for United States farm products is offered in explanation of the minor role ascribed to foreign trade. The treatment of this subject was not as complete or penetrating as one might well expect from the author. On the other hand, the assumption that a high volume of foreign trade would be associated with high-level economic stability in the United States and abroad is well taken and in considerable measure justifies the relative lack of emphasis on foreign trade.

Money likewise is given a minor role among the economic factors important to agriculture. It is asserted that, "money may have ef-

fects upon prices," indirectly through the stimulation or discouragement to investment. A small influence of the changing quantity of money may come through its effects of interest rates which in turn are related to investment as an "internal condition." The purchasing power of monetary metal producers is offered as a relatively minor "external stimulus of investment." More significance is attached by the author to the alleged fact that "... in a correlation with investment and prices, the quantity of money must be generally regarded as a dependent rather than an independent variable" and thus a result rather than a cause of economic activity.

An unbalance between saving and investment is credited with being the critical element behind the disturbing fluctuations in farm income. Idle balances from savings out of income, regardless of their location, are the culprits which change the subsequent magnitude of the income stream and lead to. (a) a new equilibrium at a lower level of prices, if prices are flexible, or (b) if prices are inflexible, a viscous deflationary circle which can be checked only by decreased saving or expanded investment.

The meaning, determining factors and significance of savings and investments are ably reviewed and reasonably well supported with data and charts. Institutional rigidities in farm prices and wages, introduced by support price legislation and labor unions, respectively, are viewed with some alarm as impediments to improvement in investment conditions. The implications of widespread rigidities in prices in the industrial sector of the economy are strangely absent from this section.

A concluding section is devoted to an able review of "Some Implications for Public Economic Policies and for Individual Action." Farmers are urged to shift their attention and efforts for aid from agricultural legislation to policies more directly related to stability of investment and non-agricultural income. Government subsidies for expanding and stabilizing the income stream should not be diverted to savings nor to consumption but rather, to increasing investment which involves a large secondary support to employment, investment and consumption.

As a parting shot farmers are advised as to self-help measures. Leading these is the ever sound advice to "... keep himself well informed. . . ." Proper management of expenses, savings, and investment are stressed in the remaining points.

CHARLES M. ELKINTON

State College of Washington.

Security for the People, Roland W. Bartlett, Champaign: Garrard Press, 1949. Pp. vii, 295.

It is commendable that an agricultural economist in a very specialized field should be concerned about broad public problems. Certainly the problem of maintaining a high level of employment is important to "high farm income." Also, as the author states, it is relevant to present day problems that might lead to World War III.

There is need for a book that would draw together and summarize the best thinking and writing on the problems of employment and economic stability. A book of this kind should be written in non-technical language, for intelligent leaders in public policy who may not be professional economists. One might hope that a book with the subtitle, "Ways of Maintaining Full Employment and High Farm Income," might do this. A reader who is looking for a book of this kind will be disappointed with *Security for the People*. It makes no claim to being such a book. Monetary and fiscal policy is mentioned in three one-sentence statements in various places in the book with the first such statement accompanied by a footnote stating, "An analysis of such policies is, however, outside the scope of this book."

The first two sentences of the preface indicate the major emphasis. "For the first time in American history, we had continued mass unemployment during the decade of the 1930's with nine million unemployed workers as recently as 1939. The major cause was the exaction of monopoly prices by a few large mass-production industries."

The author then proceeds to try to demonstrate that the problem of avoiding depressions (he does not discuss the related problem of inflation) is primarily the problem of controlling monopoly in "a few large mass production industries."

The first chapter and the last chapter are summaries. A program of action is recommended for labor, industry and agriculture. "This should include a program:

"1. Showing that the downfall of private capitalism and continued mass unemployment in European countries was caused by monopoly controls of price and production.

"2. Giving full publicity to wage and price policies of controlled industries in the United States which cause unemployment.

"3. For preventing monopolies and wasteful competition and encouraging constructive competition.

"4. For curbing monopolies by encouraging free enterprise cooperatives, chain stores, and self-sustaining or self-liquidating municipal or regional government-operated businesses to compete vigorously with independent private business.

"5. For studying the possibilities of:

a. Guaranteeing 52 checks a year to wage earners in place of the present system of an uncertain number of checks each year.

b. Gearing total wage pay rolls to some fixed proportion of sales value of product or physical volume of production in place of inflexible hourly wages.

"6. Initiating a long range educational plan for each major industrial state directed toward maintaining full employment.

"7. For developing monetary, fiscal and tax policies which will alleviate depression."

The balance of the book is devoted to discussing this kind of program, with the important omission of a discussion of fiscal and monetary policy.

It is difficult to conceive of a book written on the subject of maintaining full employment which would make no reference to the great quantity of very able and scholarly work by some of the best minds in economics in recent years. This book has a long list of references at the end of each chapter, and yet there is not a single reference to any of the writing since 1935 by competent economists which has been stimulated by J. M. Keynes, *General Theory*. It is as if none of it had been written. Though the book deals specifically with the problem of price flexibility and full employment, no reference is made to recent writing by Simons, Pigou, Lange, Modigliani, and Patinkin.

Certainly price flexibility has a bearing on maintenance of a stable high level of employment. There is, however, considerable reason to doubt how effective a successful policy of price flexibility alone (wage flexibility received little attention) would be in a dynamic society in solving the problem of maintaining a high and stable level of employment.

There seems to be no reason for completely ignoring the monetary and fiscal aspects of the problem. It is doubtful that a book on this subject which completely ignores the basic problems of aggregate demand will receive very serious consideration.

WALLACE E. OGG

Farm Work Simplification, Lawrence M. Vaughan and Lowell S. Hardin, New York: John Wiley and Sons, Inc., 1949. Pp. xii, 145. \$2.80.

This publication is the first book to be devoted entirely to the simplification of farm work, an area of study which has been receiving increased attention from agricultural economists and agricultural engineers since 1942. It is, according to the Foreword and Preface, a compilation of the experiences, methods, and results of the men who have been doing research, teaching and extension work in the agricultural colleges. The book will be welcomed by these men and, in addition, will be very useful to students, farmers, and all others who are interested in "the application of the industrially developed techniques of scientific management and engineering methods to farm work."

The first part of the book discusses the role of work simplification in American agriculture, gives empirical evidence of savings in labor by the application of work simplification techniques, lists the principles of effective work, and suggests ways in which farmers may use the results of work simplification studies. The first chapter defines work simplification as "the development and use of easier, quicker, and more economical ways of doing farm jobs." The savings of time and energy, in addition to removing some of the drudgery from farm work, may result in decreased cost and increased income. The increase in income might come from improvements in methods used on enterprises where the savings were made and from the application of labor saved to other productive work. The second chapter is devoted entirely to the presentation of statistical evidence of the amount of labor that can be saved by applying farm work simplification techniques to various farm enterprises. The third chapter gives the principles of effective work that apply to simplifying handwork, reducing chore travel, and using equipment and work crews effectively. The fourth chapter makes specific suggestions for putting across work simplification ideas to farmers and for the application of these ideas by farmers on their own farms.

The second part of the book "is prepared for those who may be planning to make a research study of work methods or teach the principles and procedures of work simplification and for reference reading by students taking courses in work simplification." Suggestions are given on organizing and conducting work simplification studies, on techniques of analysis and on teaching methods to be

used in short courses for county agents, vocational-agriculture teachers and others, and in regular high school and college courses.

The engineering aspects of farm work simplification receive major emphasis in this book with only casual mention of the economic implications. There is a tendency to advance farm work simplification as the panacea for all the problems of the individual farmer. Additional emphasis should have been given to the point that a farmer's net income will be increased by the use of work simplification only if crop and livestock productivity is increased, if costs are reduced, or if the farm business is large enough to use productively the labor saved. Possible savings in processing plants for agricultural products should have been mentioned because some of these savings would probably be passed back to the farmer in the form of higher prices for his products. Research and extension people in the state colleges do not confine their activities to the individual farm. Research and extension work in work simplification should be concentrated in the areas where the greatest savings can be made.

The second chapter appears to be an attempt to justify or sell farm work simplification and would probably have been more useful if it followed Chapters III and IV to illustrate the application to specific farm enterprises. The effectiveness of the presentation of the principles of effective work in Chapter III is lessened by giving an example first and then listing the principles. The book is well-illustrated and is written so that it can be readily understood by farmers and others interested in practical applications. It should be read by all those who are interested in farm management work.

EVERETT E. PETERSON

Michigan State College

Marketing Poultry Products, E. W. Benjamin, H. C. Pierce, W. D. Termohlen. New York: John Wiley & Sons, Inc., 1949. Fourth edition, Pp. 389, Fig. 163. \$6.00.

The term "marketing" has been used in a very broad and inclusive manner. In the Research and Marketing Act there is no specific definition of the term. However, it is generally accepted that marketing of an agricultural product begins where the crop is harvested or first purchased, and ends when the product is purchased by the consumer. Hence, a book on marketing should include not only a discussion of the physical aspects involved in bringing the

product to the consumer, but should also cover the economics of distribution. Under this latter heading might be included the factors entering into the farm-to-retail price spread, discussion of costs and efficiencies in the market operations, factors affecting supply and demand, and the effects of governmental policies on the marketing system. Also, in recent years, there has been a very healthy development in marketing books in that the descriptive material is largely used to give the student some understanding of the problems as an aid to improving the marketing system.

With these few introductory remarks in mind, *Marketing Poultry Products* is a very difficult book to review as it covers primarily the physical aspects of moving poultry and eggs to market, and in places discusses poultry husbandry. A more appropriate title might be along the following lines—How to run a poultry and egg business. There are six chapters (Chapters III–VIII) discussing feeding station and plant operations, proper plant layout, etc., but barely any reference to costs of operations or efficiencies in size of operation. There is a chapter each on the preservation of eggs and poultry. These give the proper temperatures, humidities, packing materials, etc. relating to the storing of poultry and eggs but do not mention the effects of storage on prices. The authors discuss at some length the grades and grading of poultry products (about twenty-five pages are given over to reproducing USDA grades) but not a word about the effects of grades and standardization on the marketing of the products. Chapter IX, "Transportation" sets forth the proper methods of loading and refrigerating railroad cars, but no idea of the part played by railroad rates in marketing poultry products. The chapters entitled "Retailing Eggs and Poultry" and "Advertising" tell how to retail and advertise the products but do not mention farm-to-retail price spreads, or how to reduce marketing margins.

The chapters on "The Industry" (Chapter I) and "Prices and Market Reporting" (Chapter XVII), are very incomplete. For example, there is no discussion whatsoever as to the changing seasonality of production of eggs, and its effects on prices. There is no reference to the changes in poultry meat output due to the tremendous growth of the broiler industry. There is not even a single mention of the increased size of operations of the individual producer and its effect upon the marketing of poultry and eggs. The only reference to a price analysis on eggs mentions the results of an unpub-

lished study made by the Econometric Institute for a private firm. The latest price study on poultry meat the authors could find is one made by Buechel in 1929.

Factors affecting supply, concerning which there has been much work both inside and outside government circles, is not touched upon. The statement, "the consumer demand for eggs is generally greatest during Lent when egg prices are at their low" (p. 304), indicates a lack of understanding as to the nature of demand. Other statements are open to question, such as "hedging has perhaps brought about a slightly higher market for spot eggs during the storing season."

Except for some new material on freezing and drying eggs and eviscerating poultry, this edition has little that is new or improved from the 1937 edition. In fact, the bibliography in the 1937 edition was very complete, which can't be said for the bibliography in this edition. Most of the figures are old except those on eviscerating and cut-up poultry and the freezing and drying of eggs. A particularly bad example is that of a kosher slaughter house (p. 261), which was taken at least fifteen years ago. Two new tables are presented in this edition.

To this reviewer, as a former USDA employee, it is inconceivable that the authors could write a book on marketing and refer to the work of the Bureau of Agricultural Economics only once, and then merely to mention a hatchery report. But what appears even more strange is the lack of any discussion on governmental policy.

The authors are well known and held in high repute in industry circles. Earl Benjamin, who wrote the first two editions, taught the first course in Poultry Marketing at Cornell, and for many years has been connected with the cooperative movement on the West Coast. "Doc" Pierce, who collaborated on the third edition, also taught for many years at Iowa State College, and is now Director of Poultry Research for the Great Atlantic & Pacific Tea Company. "Dewey" Termohlen, who joined the other two in writing this fourth edition, is probably the most widely known individual in the poultry industry. Among his many positions he is now the Director of Poultry Branch, Production and Marketing Administration, and President of the World's Poultry Science Association.

The 1937 edition was considered a good book in its day. Since that time, the poultry and egg industry, along with the rest of the agricultural economy, has moved forward and changed tremen-

dously. This book does not reflect that. The 1949 edition might be of some help to the novice entering the field of processing and distributing poultry products. To the student of marketing and marketing problems, there is little to be gained by its perusal.

Olson Brothers, Inc., North Hollywood, California

Urban Land Economics. Richard U. Ratcliff. New York: McGraw Hill Book Co., 1949. Pp. xii, 533. \$5.50.

Urban land economics is a young and rapidly developing field. Like the broader field of general land economics, of which it is a part, its development for the most part has come during the last 25 to 30 years. Throughout this period considerable research has been done on urban land problems and numerous concepts have been formulated. Yet this is one of the first books that attempts to organize and systematize the thinking in this field. As such, it comes as a welcome and long needed addition to the literature on land economics.

Professor Ratcliff states as his purpose the presentation of "an orderly body of facts and principles that have more or less direct application to the utilization of urban land." He advances the thesis that "the determination of urban land use is a market process" (p. vi). This thesis is developed in the organization of the book.

The first three chapters may, in a sense, be considered as introductory. Chapter 1, "The Institutional Aspects of Real Property," discusses the concept of property, or as the author writes: "deals with the commodity that is traded in the market—rights in land." The following chapters, "The Economics of Urbanization" and "The City as a Social Complex," present interesting and basic economic and social data concerning urbanization and urban areas.

Chapters 4 and 5 are concerned with the demand for residential and non-residential space. In these chapters consideration is given to the effects on the demand situation of factors such as population changes, migration, marriages, age and family status, occupation, sharing of dwellings, custom, location, consumer tastes and preferences, and the buyer's financial status. Students of farm land tenure may be surprised to learn that the subject of urban land tenure also is regarded as an aspect of demand.

The supply side of the picture is considered and developed in the chapters on "The Construction Industry," "The Building Pro-

cess," "Urban Land Credit," and "The Home Mortgage Market". As these chapter titles indicate, the author carries his discussion of the supply factors far beyond a consideration of the physical supply of urban land and the costs immediately associated with land development. Cyclical factors and movements, building costs, credit costs and terms, and the intricacies of the home mortgage market all help to explain the supply situation. The interaction between the dynamic forces of supply and demand is the subject of the chapters on the "Urban Land Market Functions and Organization" and "The Housing Market."

The discussion of "Land Income and Value" that follows these two chapters should be of particular interest to economists. In it, the author briefly treats the subjects of price, land utilization costs, value and valuation, and rent. Most of the space is given to the development of a concept of urban land rent. Urban land is regarded as a joint product in which the elements of capital and land are "inextricably mixed." The classical concept of rent as a residual, as "the waste that the enterprise can support after paying a return on the nonwasting capital" (p. 361) is regarded as unacceptable. The concepts of rent as a monopoly return and as surplus income ("the difference between costs of production including entrepreneurial return and the selling price of the product"—pp. 364-65) are also rejected. Ratcliff defines rent as "a return to land for the contribution it makes in creating want-satisfying goods and services" (p. 365). Urban land rent is determined by supply and demand in terms of opportunity costs. It is a part of price and over the long run competition can be expected to keep entrepreneurial rents in line with economic rent.

The discussion of land income and value lays the groundwork for the author's treatment of the subjects of urban land use and city growth. These are discussed in the chapter on "City Growth and Structure." Consideration is given in this chapter to competition of uses, situs or location factors, and to the specific factors that influence the location of various types of retail establishments.

Chapter 14 deals briefly with a variety of "Urban Land Policies," including city planning, zoning, subdivision control, taxation and urban redevelopment. This is followed by two chapters on "The Economics of Housing Policy." They deal with the nature of the housing problem, the control of instability, reducing the costs of shelter, and means for handling the problems of substandard hous-

ing conditions. The analysis in these chapters is interesting and commendable but at the same time seems to stand out as an appendage to the rest of the book.

Looking at the book as a whole, one must admit that it has many merits. It is a fat volume, is well written and very readable. The approach is new and somewhat different from that employed in standard textbooks in general land economics. The author has made a very real contribution in drawing together many of the concepts of his field. Many sections of this book, such as his account of the building cycle in Chapter 7, his analysis of the "filtering-down" process in his chapter on "The Housing Market," and his discussion of housing costs in Chapter 15, are particularly commendable.

In the eyes of this reviewer, the book has many good and praiseworthy characteristics, but also some aspects that are subject to criticism. Some of the data reported, as in Tables 23, 24 and 25, seem to be strangely out of date in 1949. The various chapters are well documented but their value for class purposes could probably be improved by the addition of a bibliography or a listing of selected references at the end of each chapter.

As one might expect, most of the analysis and discussion centers around the problem of urban housing and space for housing. Professor Ratcliff is to be commended for the attention he gives to commercial and industrial land uses. He could have improved his over-all treatment, however, had he given more than a page and a half to the discussion of the use of urban lands for streets, parks and other public and semi-public uses.

The greatest weakness of this book lies in the limited emphasis it gives to the basic and underlying economic principles that affect land use. In his various chapters the author shows considerable ability in using economic tools of analysis, but on the whole he tends to overemphasize the institutional aspects of the field to the neglect of the economic aspects.

The book is described by the publisher as "a foundation work which is fundamental but not elementary." In this sense the author may be justified in assuming some reader-awareness of a number of economic concepts. As a class textbook, however, too much is probably assumed concerning the average student's awareness and understanding of the basic concepts and theory of land economics. This reviewer feels that more than passing mention or consideration should be given to the concepts of intensity of land use, the

principle of diminishing returns, ripening and supercession costs, the property valuation process, and the concept of fixity of investments in landed property. Mention should at least be made of the operation of the principles of comparative advantage and first choice. Also much more space should be given to the subject of property valuation and appraisal. The capitalization approach to valuation is very briefly discussed and little, if anything, is said about the market analysis and cost of reproduction approaches that are so commonly used in urban land appraisals.

NEWS NOTES

The book "Readings on Agricultural Policy" published by the Blakiston Company is now available (See advertisement in this issue.) This book is the result of action taken by the American Farm Economic Association at its 1947 meeting when it approved a proposal of the Executive Committee that the Association undertake to publish reprints of articles in various fields of agricultural economics. The Editorial Council of the Association selected agricultural policy as the field for the initial volume and invited O. B. Jesness to assume responsibilities for editing the volume.

Martin A. Abrahamsen has re-joined the Cooperative Research and Service Division of Farm Credit Administration as principal agricultural economist in charge of the Cooperative Purchasing Section. For the past four years Dr. Abrahamsen has been professor of agricultural economics in charge of research and teaching in marketing at North Carolina State College.

Henry A. Allpress has accepted an appointment in Rural Economics at the University of Nebraska. His present work is on poultry and egg marketing.

M. E. Andall of the Saskatchewan office of the Economics Division, Federal Department of Agriculture, has returned after having been on leave for the academic year to pursue graduate work at Michigan State College.

Norris J. Anderson, formerly Professor of Agricultural Economics at Kansas State College, is now Extension Economist at the University of Nebraska.

G. M. Beal, Professor of Marketing in the Department of Agricultural Economics and Marketing at the University of Maryland, has been made Head of the Division of Marketing in the Department.

Karl Brandt, economist and professor of agricultural economics of the Food Research Institute of Stanford University returned April 10 after a year's sabbatical leave during which he lectured at Heidelberg, Gottingen and Geneva Universities and travelled extensively in Germany, France, and Italy.

Harley M. Brewer, of the Agricultural Estimates staff of the Bureau of Agricultural Economics, has been in Kansas helping with a pre-harvest wheat survey similar to those made in the late 1930's and the early 1940's.

Owen L. Brough has been promoted to assistant professor at Iowa State College. His major field is livestock marketing.

W. Herbert Brown, recently at Harvard University, has joined the Farm Management staff of the Bureau of Agricultural Economics and has been assigned to the Farm Costs and Returns section.

Arthur C. Bunce, who has been Economic Advisor to the Commanding General of South Korea with the rank of minister, has recently been assigned to the position of Chief of the Economic Cooperation Administration in South Korea.

R. P. Callaway, formerly Professor of Agricultural Economics and Extension Marketing Specialist at the University of Maryland has joined the staff of the Potato Division, Fruit and Vegetable Branch, Production and Marketing Administration, U.S.D.A.

James P. Cavin, Head of the Division of Statistical and Historical Research, Bureau of Agricultural Economics, is with the Paris office of the Economic Cooperation Administration, where he is working on East-West trade problems. He will return to the Bureau in September.

Edward C. Collins has joined the staff of the Fruit and Vegetable Section of the Cooperative Research and Service Division of Farm Credit Administration as associate agricultural economist. Mr. Collins has been employed for the past two years as assistant professor of economics at North Carolina State College.

Albert R. Conley, student and research worker in the graduate school at Ohio State University, has been appointed associate professor of agricultural economics at the University of Missouri and will assume his duties there on September 1. He is filling a vacancy left by the resignation of Dr. E. H. Matzen, who joined the Farm Credit Administration last winter. Mr. Conley is completing his work for the Doctor of Philosophy degree at Ohio State University.

Ivan L. Corbridge joined the Agricultural Economics staff of the State College of Washington, January 1, 1949, as Assistant Professor and Assistant Agricultural Economist. His duties involve research and teaching in marketing.

Rex Daly has returned to the staff of the Bureau of Agricultural Economics. He has been with the Illinois Agricultural Experiment Station where he worked on a Research and Marketing Administration project which dealt with methods of measuring farm expenditures and income.

Miss Loa E. Davis joined the Division of Agricultural Economics, Extension Service, U.S.D.A., in May to assist with marketing projects in consumer education conducted under the Research and Marketing Act. Miss Davis was in Washington with the Extension farm labor program in 1945 and since then has been attending Teachers College, Columbia, and serving as home demonstration agent in Frederick County, Maryland.

J. S. Davis, director of the Food Research Institute of Stanford University, returned June 10, after having spent ten weeks at the Institute for Advanced Study in Princeton, New Jersey, and ten weeks in the spring on an observation tour of the southern states.

Walter King Davis, a recent graduate of the Florida College of Agriculture, has joined the staff of the Cooperative Research and Service Division, Farm Credit Administration, as junior agricultural economist.

J. M. Dawson and M. Rachlis, who have been on leave of absence for further graduate work at the University of Illinois and Purdue University, respectively, have returned to their duties in the Economics Division, Dominion Department of Agriculture, Ottawa.

R. J. Doll, Kansas State College, is a visiting professor at the University of Arkansas for the first summer session. He will teach courses in Agricultural Policy and Agricultural Economics.

Phil S. Eckert, formerly head of the Department of Agricultural Economics and Rural Sociology, Montana State College, resigned last December to accept a position as specialist in the field of international exchange of agricultural commodities with the Economic Cooperation Association. Dr Eckert is stationed in Paris and travels throughout the sixteen cooperating nations.

Paul A. Eke, Head of the Department of Agricultural Economics at Idaho, returned July 1 from a year of sabbatical leave. He spent his leave in writing and study at the University of Chicago and travelling in European countries.

William H. Fippin has resigned from the staff of the Bureau of Agricultural Economics to accept an appointment in the Foreign Service of the State Department as chief of agricultural training for the American Mission in Korea.

H. C. Filley retired as Chairman of the Department of Rural Economics at the University of Nebraska on July 1, and will leave the University to enter other work September 1. His successor is Dr. C. Clyde Mitchell who has recently been working with Dr. Black at Harvard.

Walter U. Fuhrman has transferred from the Department of the Interior to the Bureau of Agricultural Economics, where he serves as leader of the Western Agricultural section, Division of Farm Management and Costs

Marshall Godwin, who has just completed work for a Ph.D. degree at Cornell University, has been appointed Associate Professor in the Department of Agricultural Economics and Marketing at the University of Maryland. Dr. Godwin will teach courses and conduct research in fruit and vegetable marketing.

George H. Goldsborough has re-joined the Cooperative Research and Service Division of Farm Credit Administration as senior agricultural economist in the Fruit and Vegetable Section. He has been employed for the past year with the Rural Electrification Administration

Wade F. Gregory, formerly of Pennsylvania Agricultural Experiment Station has accepted a position at the Alabama Agricultural Experiment Station as assistant agricultural economist in charge of a Feed Utilization Study. The project is jointly supported by the Station and Bureau of Agricultural Economics.

Ernest Grove of the staff of the Bureau of Agricultural Economics has received a Ph.D degree from the University of California. His dissertation is on income parity for agriculture.

Clifford M. Hardin has been appointed Director of the Agricultural Experiment Station, Michigan State College, effective July 1, 1949, to succeed Director V. R. Gardner, who retired at that time.

H. R. Hare, formerly Agricultural Advisor, Employment Service, Department of Labour, Ottawa, has been appointed Superintendent of Farm Development, Soldier Settlement and Veterans Land Act, with headquarters at Ottawa.

Charles W. Hauck is now in charge of the Fruits and Vegetables Marketing Section, Division of Agricultural Economics, Extension Service, U.S.D.A. He has been stationed in Washington since February 1949, hav-

ing transferred to this post from Ohio State University, where he was engaged in research and teaching in the marketing of fruits and vegetables from 1926 to 1949

Cecil B. Haver has returned to North Dakota Agricultural College after a quarter's leave of absence granted him to complete his Ph.D. work at Iowa State College.

G. V. Haythorne, Research and Statistics Branch, Department of Labour, Ottawa, recently completed requirements for a Ph.D. degree at Harvard University.

Jimmy S. Hillman, Assistant Professor, Department of Agricultural Economics, Mississippi State College, has been on leave doing advanced work at the University of California and will continue on leave during the coming academic year.

E. C. Hope, formerly Professor of Farm Management at the University of Saskatchewan, has been appointed Economist for the Canadian Federation of Agriculture with headquarters at Ottawa.

S. C. Hudson, Economics Division, Dominion Department of Agriculture, Ottawa, has been elected President of the Canadian Agricultural Economics Society for the coming year. Hadley VanVliet of the University of Saskatchewan is vice-president. The Councillors are I. S. MacArthur, A. H. Turner, W. D. Porter of Ottawa, and C. C. Spence of Edmonton, Alberta.

Buis T. Inman has been appointed assistant head of the Division of Land Economics, Bureau of Agricultural Economics, as well as leader of the field work of the Division.

Hilhard Jackson has been appointed Assistant Professor of Rural Economics and Sociology, University of Arkansas, effective August 1. Mr. Jackson attended the Regional Agricultural Marketing School, North Carolina State College, during the summer and was formerly employed jointly by the University of Arkansas and Bureau of Agricultural Economics.

E. Jaska recently joined the staff of the Economics Division, Dominion Department of Agriculture, Ottawa. For the past 15 years Dr. Jaska, a native of Estonia, has done research in agricultural economics at the Universities of Tartu and Jenna and has edited economic journals in Tallinn, Estonia.

Harold R. Jensen has been promoted to assistant professor at Iowa State College. His major field is farm management and production economics.

Hugh A. Johnson, a member of the Farm Management staff of the Bureau of Agricultural Economics since 1941, is now an agricultural economist at the Agricultural Experiment Station, Fairbanks, Alaska. He has recently been located at Purdue.

Earl L. Johnston, formerly with the Division of Agricultural Relations, Tennessee Valley Authority, has joined the North Carolina Agricultural Extension Service staff as Marketing Specialist in the Department of Agricultural Economics.

C. Del Mar Kearn has accepted a position as Assistant Professor in

Farm Management in charge of Farm Cost Account work at Cornell.

M. M. Kelso, Professor of Ranch Management at Montana State College, has been designated head of the Department of Agricultural Economics and Rural Sociology and of the Department of Economics and Sociology. He fills the position left vacant by the resignation of Dr. P. H. Eckert, formerly head of the two departments.

J. W. Kirkbridge is transferring from the Kentucky office of Agricultural Estimates to the Washington office of the Bureau of Agricultural Economics.

G. E. Korzan, Assistant Professor of Marketing in the Department of Agricultural Economics and Rural Sociology at Montana State College, has resigned that position to accept a similar one at Oregon State College.

Baldur H. Kristjanson received his Ph.D. degree from the University of Wisconsin in June and has been promoted to the rank of Associate Professor of Agricultural Economics at North Dakota Agricultural College.

Charles N. Lane, Agricultural Economist with the Economic and Credit Research Division of the Farm Credit Administration, has recently joined the staff of the Central Project Office in the Agricultural Research Administration, Washington, C. D.

L. C. Lanford is teaching two courses in Agricultural Economics at the Abraham Baldwin Agricultural College, Tifton, Georgia.

J. Lattimer, Department of Farm Economics, Macdonald College, has been elected a Fellow of the Agricultural Institute of Canada.

Jerry M. Law has been appointed as cooperative agent on southern regional poultry and egg marketing work and will be located at the University of Arkansas, Fayetteville. He had been on the staff of the Department of Agricultural Economics, Louisiana State University.

John E. Mason, for the last 2 years a member of the Farm Management staff of the Bureau of Agricultural Economics, died June 10 at the age of 40, following a week's illness. A native of Tennessee, Mr. Mason had been employed in the Department of Agriculture at various field stations and in Washington for 12 years.

Michigan State College students have organized a student section of the American Farm Economics Association. Dr. Arthur Mauch and Dr. Karl A. Wright of the Agricultural Economics Department are the faculty advisors.

George Montgomery has returned to Kansas State College to resume his work as Head of the Department of Economics and Sociology. He has been doing graduate work at the University of Minnesota.

R. G. Murphy has resigned his position as acting Assistant Professor of Farm Management Extension at Cornell University, and will continue in graduate work at Cornell to complete requirements for a doctor's degree.

R. A. Murray has resumed his duties as Professor of Agricultural Economics at State Teachers College, Platteville, Wisconsin, after completing requirements for a Ph.D. degree in Farm Management at Cornell University.

Max Myers is expected to return to the Agricultural Economics Department of South Dakota State College in September, after receiving the Ph.D. degree at Cornell University.

Claude Nash retired from active duty in the Department of Agricultural Economics at Michigan State College on June 30, 1949. He was Extension Specialist for 18 years in agricultural marketing following 15 years as County Agricultural Agent.

Ottar Nervik received his Ph.D. degree in Economics at Harvard University in July and is now affiliated with the Economics Department of South Dakota State College.

Arthur G. Peterson has returned to the Munitions Board, Office of the Secretary of Defense as Chief of the Textiles, Forest and Agricultural Products Branch, after spending nearly a year as Chief of the Statistics Division of the National Economic Board in Seoul, Korea.

Homer S. Porteus, formerly county agricultural agent in Ohio, has joined the staff of the Division of Agricultural Economics, Extension Service, U.S.D.A., as extension economist in marketing.

Winston E. Pullen, Assistant Professor of Agricultural Economics and Farm Management at the University of Maine, will be on leave of absence for the coming academic year to pursue graduate study at Cornell University.

Philip M. Raup has joined the Land Economics staff of the Bureau of Agricultural Economics as a cooperative employee with the Wisconsin Agricultural Experiment Station. He recently returned from 3 years in Berlin with the Office of Military Govt.

John C. Redman will be on leave from Mississippi State College during the coming year, doing advanced work at the University of Kentucky.

Fred B. Saunders, who received his Master's degree in Agricultural Economics, in June 1949 at the University of Georgia, has accepted a position at the Berry Schools, Mount Berry, Georgia, where he will teach courses in Agricultural Economics.

Rainer Schickele of North Dakota Agricultural College has been elected Chairman of the Northern Great Plains Tenure Committee of the 1949-1950 term.

Leonard Schruben has joined the staff at Kansas State College and will be in charge of the work in grain marketing.

Raymond C. Scott has been appointed Associate Professor in the Department of Rural Economics and Rural Sociology at Ohio State University and Ohio Agricultural Experiment Station. He will work in the field of fruit and vegetable marketing, research and teaching.

Geoffrey Shepherd returned in the middle of June from six weeks in western Germany. He assisted the Bipartite Control Office, Food and Agriculture Group, at Frankfurt, and western German agricultural economists and officials in developing a long-range price policy for western German agriculture.

Professor Edward A. Duddy of the School of Business, University of Chicago, has a file of the Journal of Farm Economics, 1924-1948, with the exception of two numbers missing which he will sell for \$50.00.

CANADIAN AGRICULTURAL PRICE PROBLEMS AND POLICIES: A COMMENTARY

W. M. DRUMMOND
Ontario Agricultural College

THIS issue of the Journal contains several articles which deal in considerable detail with some of the more significant Canadian market and price regulating programmes. The specific programmes selected are, generally speaking, currently operative and of fairly recent origin. While the list chosen constitutes only a major sample of existing programmes and makes no attempt to include those which have been attempted at various times in the past, it does serve to illustrate the variety of approach adopted as well as the special and general character of the problems encountered and principles employed. The present paper is intended to act as more or less of a supplement to the other articles. Instead of discussing any particular programme or programmes as such, it aims at drawing attention to certain general factors or influences which help to explain why certain policy choices have been made. To a considerable extent it is a statement of the general underlying influences at work, the general methods used and the general results obtained. Its central thesis, if such it may be called, is that the special attempts which Canada has made to influence agricultural prices, either directly or indirectly, have been in large measure dictated by the special set of influences and circumstances which have prevailed. This is not to say that the steps taken were the only ones that could have been taken in every case. All that is suggested is that there has been a pronounced correlation between the special situations in which Canada has been placed and the kinds of action programmes decided upon. While this is likely to

be true to some degree of every country, it has been particularly so in the case of Canada.

The Dependence on Exporting

The large scale dependence on export markets is undoubtedly the most important of the several underlying factors conditioning Canadian policy. While this dependence has always been most pronounced in respect to wheat (around 70 per cent of production had to be exported), it has been very marked in the case of several other major products. It has always been necessary to export significant percentages of livestock and livestock products and such things as apples, potatoes and tobacco. Indeed there are very few products which have not been on an export basis to some degree at certain seasons at least. Whatever the situation regarding any specific product, a very large part of the total of Canada's agricultural production must find an export outlet.

This dependence on exporting leads naturally to several conclusions in respect to price policy. The first is that Canadian farmers as a class must be prepared to accept prices in line with those available in the world outside. Under normal conditions Canadian prices must tend to coincide with world prices. A second conclusion is that, so far as the great bulk of Canadian production is concerned, it is impossible to raise the price merely by imposing a protective tariff since importation does not normally occur. In the third place, the necessity of finding large export markets will virtually compel Canadians to keep costs and prices as low as possible in order to ensure success in international price competition. Also, any hope of price improvement lies in the direction of demand expansion rather than supply contraction. It is for this reason, of course, that any general policy of production curtailment of Canada's major products must be considered as part of an international policy. Finally this conclusion regarding the desirability of expanding demand rather than contracting supply tends to emphasize the wisdom of supporting every programme that seems calculated to maintain or expand demand. This goes far to explain why Canada has given such active support to the international trade agreement programmes both pre- and post-war, why she has been so anxious to consummate definite export contracts, and why her farmers have recently been so strongly behind the international commodity agreement idea. In the final analysis the strongest motivating force

in Canadian policy-making today is probably the belief amounting to a conviction on the part of those at the top level—in both government and farm circles—that it is not possible for agriculture or any other section of the body economic to secure satisfactory prices or levels of prosperity in the absence of an internationally expanding economy.

Relative Importance of Agriculture in the Economy

Even though the large dependence on exporting makes it necessary to think in terms of selling at world prices, Canadian farmers might well receive the equivalent of considerably higher prices were the non-agricultural sections of the economy capable of contributing sufficiently to this end. Price additions might take the form of supplementary payments or direct or indirect subsidies. In any such programme, however, it is obvious that the extent of the contributions on behalf of agriculture must depend upon the relative importance of the agricultural industry in the national economy. If agriculture were a relatively insignificant part of the total picture it might receive sizable contributions from the non-agricultural sectors without seriously affecting the income status of the latter. The truth of the matter is, however, that, regardless of the basis of measurement used, agriculture represents a very large part of the country's economic life even though its relative importance has been decreasing in recent years. To provide Canadian farmers with anything really significant in the way of price assistance would require an extremely large total contribution and much more than the rest of the economy could afford or be expected to give. Just how much it could afford is something that is extremely difficult to decide except in the most arbitrary sort of fashion. One possible indication of the limited extent to which agricultural prices might be added to in this way is seen in the total amount of funds provided for price stabilization operations under the Agricultural Prices Support Act.¹ That Act provides for a revolving fund of 200 million dollars. When it is remembered that this amount has to finance the price stabilization operations of all products other than wheat; that during the transitional period in which the Act was intended

¹ 8 Geo. VI, c. 29, An Act for the Support of the Prices of Agricultural Products during the transition from War to Peace, Assented to Aug. 15, 1944. For details of operations under this Act see the article by A. H. Turner in present issue of this Journal.

to be operative the government did not anticipate additional expenditures in respect to wheat; that it was apparently not thought possible or desirable to make even this amount available for more than a limited period; and that the implementation of this stabilization programme tended to coincide with the elimination of other previously-existing agricultural price subsidies, one can get some idea of its price-supporting value. So long as the number of commodities requiring price assistance is small enough and the period during which the assistance needed is short enough the amount of funds provided can render a real degree of price support.² The situation would be very different, however, were a general and severe drop in demand to occur making it necessary to support the prices of all or a large number of commodities simultaneously and for extended periods. Just how far 200 million dollars would go in raising prices under such circumstances can perhaps best be realized by comparing this figure with the total income from farm products exclusive of wheat in recent years.

This apparent fact that the national economy simply cannot afford to support farm prices to more than a very limited extent has several important implications from the standpoint of price policy. Perhaps the most important of these is that, in periods when prices in general are low, there would appear to be no possibility whatever of the Canadian government undertaking to keep farm prices at parity levels as has been done in the United States. There would simply not be enough money forthcoming to make this possible. For the same reason it would not be possible to ensure prices in line with cost of production as in the United Kingdom. This is probably another way of saying that Canadian farm price floors will probably have to be kept at relatively low levels for purely financial reasons. Another important point is that, under anything like emergent conditions, the Canadian price authorities may well be forced to choose between spreading the available funds over a long list of products or restricting their price support aid to one or a few key products particularly susceptible to price depression. Anyone familiar with the various types of governmental assistance given to Canada's wheat-producing enterprise from 1929 on cannot but be impressed with the extent to which the use of funds may have to be concentrated.³ In that case an absolutely key enterprise in

² *Ibid.*

the agricultural and general economic structure was in special need of help partly because it was subjected to abnormally adverse weather conditions; partly because the commodity concerned was universally produced and was characterized by a highly inelastic demand; partly because such a large percentage of the product had to be exported, and partly because the producers were so largely dependent on the income from a single commodity. Still another consequence of this limited supply of price-support funds is the necessity of using the funds in such a way as to obtain the greatest possible price-raising benefits. Moreover, since the funds are likely to be small in proportion to the price-supporting requirements, particular care may have to be taken to see that the methods of raising and spending them are the most justifiable methods in the minds of contributors. It might well be, for example, that the latter would be more willing to support a food allotment plan aimed at raising the nutritional levels of low-income consumers than one designed to give direct cash payments to farmers. Whether a given expenditure on a food allotment programme would have a greater net effect in supporting farm prices than direct cash payments to farmers would also have to be seriously considered.

Specialization and the Dominance of Wheat

As is well known the specialized production of spring wheat in the three Prairie Provinces has long been a major enterprise in Canada's agriculture. The reasons for this specialization are too familiar to the readers of this Journal to require reiteration here. Suffice it to say that the soil and climate combined with the natural topography of this area provide an unusual opportunity for efficient production of a high quality product and, in considerable sections of the area, apparently do not invite favourable alternative opportunities. The general result is that, for the area as a whole, receipts from the sale of wheat have long formed and continue to form the main source of farm income. It is not surprising, therefore, that the farmers in these provinces have been particularly concerned about wheat-marketing methods and wheat prices. Speaking summarily it may be said that for the first three decades

Market by H. L. Griffin in the Canadian Journal of Economics & Political Science, Aug. 1935; *Observations on Canadian Wheat Policy since the World War* by H. S. Patton in the May 1937 issue of the same Journal; *Wartime Wheat Policy in Canada* by H. S. Patton in the Nov. 1942 issue of this Journal; *Dominion Aids to Wheat Marketing, 1929-39* by V. C. Fowke in the Aug. 1940 issue of Canadian Journal of Economics and Political Science

of the present century farmer effort was concentrated on finding ways and means of obtaining the largest possible part of the world price at which the wheat finally had to be sold.⁴ During the 1930's emphasis shifted to ways and means of maintaining the marketing methods that had been developed and securing from the federal government sufficient financial aid to provide at least a semblance of security and stability. In very recent years the real drive has been in the direction of a reasonable degree of price and income stabilization.

It is important to note that throughout this half century of uninterrupted effort governments, both provincial and dominion, have been called upon to render assistance. The assistance given has varied all the way from the appointment of Royal Commissions, provision of grain-marketing legislation, providing loans for the construction of farmer cooperative elevator systems, actual building and operating of country and terminal elevators, guaranteeing bank loans for cooperatives, undertaking large scale purchase of wheat futures in an attempt to prevent wholesale price reductions, guaranteeing minimum prices for wheat, making cash grants in specially distressed areas and, in recent years, undertaking to market all the wheat under government auspices and arrange annual or longer term contracts for the sale of wheat. This extensive degree of governmental intervention has not been undertaken without good reason. For one thing it must not be forgotten that the successful and large scale development of agriculture in the Prairie Provinces has long been regarded by successive Canadian governments as an absolute prerequisite of general Canadian prosperity. To a very large extent an economically healthy condition on the part of western Canadian farmers has been regarded as the best, and indeed only, assurance of prosperity throughout the nation. Western development was deliberately sponsored by the government not only because it was expected to supply a field for investment and business for those providing financial and transportation services but also because a major market was needed for industrial goods manufactured in the older Central Provinces.⁵ In the second

⁴ For a complete and chronological account of the development during these years see *Agricultural Cooperation in Western Canada* by W. A. Mackintosh, published in 1924 by the Ryerson Press. Also, *Grain Growers' Cooperation in Western Canada* by H. S. Patton, Harvard Univ. Press, 1928.

⁵ See address entitled "Western Agriculture in the Canadian Economy" by W. A. Mackintosh in Proceedings of the Conference on Markets for Western Farm Products, Dec. 12, 1938. Obtainable from King's Printer, Govt. of Manitoba, Winnipeg.

place the very fact that dependence on wheat in the West has been so pronounced has resulted in a special need and demand for government assistance. The need has been great because wheat producers were a long distance from their final market; because, being specialized, they have been unable to spread their risk; and because the demand for wheat is extremely inelastic. The demand has arisen partly because specialists are naturally more interested in the marketing of their special crop than general farmers are in the marketing of any one of their several products; partly because producers felt themselves subjected to glaring marketing abuses and completely lacking in bargaining power; partly because they have realized the government's dependence on their political support, but mainly because they have encountered severe economic adversity.

In view of the current Canadian interest in agricultural price stabilization, it may be in order to indicate the special interest of the wheat growers in the concept together with the basic reason for this interest. The wheat growers have pioneered the way, supplied the real spark and applied consistent pressure in respect to price stabilization. While there are probably several reasons for this, including their large numbers and effective organization, the main one undoubtedly is that they, more than any other group in Canadian agriculture, appreciate the possible maleffects of extreme price instability. Moreover the experience during the early 1930's has convinced them and the government as well that, under conditions of drastic and persistent price decline, it is entirely impossible to operate a pooling plan in the absence of a minimum price guaranteed by the national government. Since pooling does serve to mitigate seasonal price fluctuations the great majority of producers have been anxious to maintain this principle in operation.

If the experience in the early depression years proved the necessity of government financial help in order to preserve pooling, it also made it clear that even the national government was unable to raise minimum prices above very low levels. The knowledge that there are definite and early limits to the degree of price support which Canada unaided can give is at least partly responsible for this country's readiness to participate in such undertakings as the four-year wheat contract with Britain or the recently negotiated international wheat agreement. This willingness represents a hope that what she cannot hope to do alone she may be able to do with the aid of other countries. There is, of course, another and very important consideration which undoubtedly helps to explain why

Canadian governments have been willing to experiment with various methods aimed at giving wheat producers a greater degree of economic stability. It so happens that the basic character of Canada's resources virtually compels her to undertake large scale production of a few products which have to be disposed of, for the most part, in foreign markets. Moreover they are products which are particularly susceptible to immediate and pronounced drops in demand if and when international economic conditions become unfavourable. The general result is that the economy as a whole has been found to be inherently unstable. In view of this and because of the truly integral position which the wheat production enterprise occupies and because it is in many ways the most exposed and unstable of all Canadian activities, any programme that seems likely to ensure a greater measure of stability in that sphere has been looked upon as being in the national interest. Furthermore the realization that a really serious drop in wheat prices if continued is bound to result in wholesale transference from wheat growing to production of farm products which other Canadian farmers are producing and for which there is only a limited market may help to suggest why the government has felt it was good business to devote a major part of its total stabilization effort to the wheat situation. The attempt to bolster wheat prices has been, to a very considerable degree, an attempt to bolster farm prices in general. Finally it may be said that anything in the way of price stabilization assistance which the government may find it possible to give is looked upon as something which may at least partially offset the price-raising effects of the national protective tariff policy to which the wheat growers have been particularly subjected.

— *Some Effects of the General Wartime Price Control Policy*

Throughout the period of the Second World War Canadian authorities enforced a programme designed to maintain specific relationships between certain prices and to prevent serious increases in the general price level. As is well known the implementation of this price control policy required large scale substitution of direct and arbitrary regulations for the control normally exercised by the price system. When the policy was instituted in September 1939 and for nearly two years after, farm prices were low in relation to prices of the things farmers had to buy. Moreover this general relationship had existed for many years prior to the war. Between

the start of the war and the application of the general price ceiling in the late autumn of 1941 the rise in farm prices, on the average, was comparatively small and the net price position of farmers had actually worsened. Despite farmer protests the actual prices were kept at or near the ceiling levels which prevailed at the end of 1941, although definite and sizeable increases were permitted in a few cases where continuance of existing prices would have meant obvious injustice. For the most part any additional economic inducements took the form of direct and indirect subsidies and it was not until after the war, when price controls and subsidy payments were gradually eliminated and the general world scarcity caused farm prices to rise, that farmers received much extra remuneration in the form of increased prices in the true sense. Moreover the general policy, when permitting price increases or granting subsidy payments during the war, had been to offer only that amount of inducement needed to obtain a desired volume of production.

While farmers benefited financially as the war period proceeded and as the volume of sales and amount of subsidy payments increased, they never became really reconciled to either the subsidy idea or the concept of a ceiling on their selling prices. Realizing that subsidy payments were bound to disappear and believing that the price control policy had prevented them from receiving anything like as much returns as they would have received under uncontrolled price conditions, and realizing also what had happened to the price of farm products after previous wars, farmers began to press for some degree of protection against future possible price declines. Their attitude is well illustrated by the following quotation: "If Canada can maintain a general price ceiling in wartime to save us from the disasters of out-of-hand inflation, our farm people believe that in the postwar period Canada can just as logically establish and maintain a general price floor to save us from equally disastrous deflation."⁶ This statement makes it fairly obvious that the farmers were thinking in terms of postwar compensation for something that had been denied them during the war. It also suggests not only that they believed it technically possible for the government to give this compensation but that to attain this result it was quite in order, if necessary, for the government to employ

⁶ From an address delivered in 1942 by H. H. Hannam, President of the Canadian Federation of Agriculture. The fact that this statement was made as early as 1942 is in itself significant.

marketing techniques and a degree of arbitrary regulation corresponding to that of the war period itself. Indeed the inference is that the postwar period might well constitute a peacetime emergency warranting any degree of governmental intervention that might be found necessary and useful.

At this point one might enquire as to the soundness of the logic in the quotation cited above. This seems desirable inasmuch as there has never been any doubt raised in regard to the matter so far as this writer is aware and because the success of specific programmes which may be partly due to its unquestioned acceptance might well depend on the validity of this basic claim. It is not possible, due to lack of space, to discuss the question here in any detail. One may, however, raise two or three questions. For one thing is it reasonable to expect that Canadians generally would actually submit to anything like the wartime degree of government regulation in order to meet a purely economic peacetime emergency? In particular would they submit to the wartime levels of taxation in order to provide funds for maintaining employment, purchasing power and farm prices? In the second place is it safe to assume that, in a period when "disastrous deflation" threatens, there will be as much national income available to bolster falling prices as there was in wartime to pay price subsidies? Of course the answer to these questions may be that no really pronounced degree of price support was ever contemplated and that the programme of financing would therefore be entirely feasible. Nevertheless these questions would seem to warrant some consideration.

Most of the special agricultural price support programmes thus far provided are outlined in some detail in other articles in the present issue of this Journal. They include the current four-year wheat agreement, the operations under the Prices Support Act of 1944, the recently-arranged plan for marketing coarse grains through the Dominion Wheat Board and the 1949 enabling legislation which gives provincial marketing boards the legal authority to operate in interprovincial and international trade.

In respect to the last-mentioned legislation it may be said that, ever since the federal Natural Products Marketing Act was finally declared unconstitutional in early 1937, organized agriculture has been making annual requests for something that would act as a substitute and the 1949 legislation has been designed for that purpose. Just what use will be made of it remains to be seen. The

insistent demand for such legislation, however, requires a word of explanation. The explanation is probably many-sided. Many of the commodities involved in the schemes which operated under the original Natural Products Marketing Act of 1934 and those more recently dealt with in schemes operated in some of the provinces are consumed mainly if not entirely in the domestic market. This might suggest that in some cases there has been a desire to raise the price by limiting the supplies offered for sale. One cannot but feel, however, that the central interest has lain in the possibilities of securing a larger part of the true supply and demand price. To this end quite a few of the schemes have attempted to secure whatever benefits collective bargaining may bring by arranging prices through negotiation. Where arranged in advance of production these negotiated prices have acted as forward prices as well. In other cases an attempt has been made to secure higher average prices by stressing more orderly marketing. In still other cases the emphasis has been on regulating the market in such a way as to raise the average quality, replace inefficient by more efficient methods, and generally reduce the marketing spread. Generally speaking it would appear that greatest success has been achieved where no really scientific market organization had previously existed, or where the products concerned were produced in limited areas and by relatively few producers or where the producers were strongly organized and ably led.

Much remains to be said regarding the influence of the general wartime price policy on war and post-war agricultural stabilization efforts. There can be no doubt, for example, that the mere implementation of that policy did much to condition the minds of farmers and governmental authorities as well to the stabilization idea together with the possibilities of its successful application. It is also true that farmers, by and large, were favourably impressed by the wartime practice of announcing definite prices well in advance of production. And it should not be forgotten that the wartime plan to encourage production of coarse grains, livestock and livestock products rather than wheat in the Prairie Provinces along with the determination to prevent increases in the cost of living index go far to explain why the government decided to take complete charge of wheat marketing in the autumn of 1943. At that time wheat futures prices were rising rapidly and would undoubtedly have risen much more had open market dealings been allowed to continue.

Effect of the "National Policy"

In 1878 the government of Canada adopted what has ever since been known as the National Policy. Its aim was the gradual development of a more balanced type of economy. To encourage secondary industries the government undertook to provide a very considerable degree of tariff protection. One general result of this policy has been that agriculture, which has, generally speaking, been unable to use the tariff to raise its selling prices, has had to pay prices for the industrial goods which were very considerably higher than would have prevailed in the absence of the tariff protection. The main significance of this circumstance from the standpoint of farm price policy is that farmers, in search of a net improvement in their price position, have felt impelled to place special emphasis on ways and means of reducing their buying prices. Price reduction has been sought partly through tariff reduction and partly through an expansion of cooperative purchasing. To some extent efforts have been made to offset the high prices with reduced transportation rates. Whatever the method, the point to remember is that reduction of the prices which farmers have to pay has been and still is a most significant part of farm price policy.

Some Final Observations

While the most important factors influencing price policy have probably been mentioned, there are undoubtedly others of some consequence. In particular, Canada's extreme and continued reliance on the British market has no doubt forced this country at times to adjust policies in line with British policies and requirements. For example, the adoption of fixed annual prices in the Canadian-United Kingdom contracts during recent years, while partly dictated by the special wartime needs, has also represented an adjustment to the bulk purchase policy advocated and practised by the present British government. Another entirely different sort of influence that might be mentioned is the great size of the country and the wide diversity of farming interests and enterprises. Whether a price policy should favour growing all the feed grain in the West or feeding as well as growing it in that area or aim at discouraging the growing of potatoes in Ontario and encouraging the growing of them in the Maritimes are among the many unsettled questions in the minds of Canadian policy makers. In connection with this matter the heavy transportation costs resulting from the tremendous haulage distances constitute a serious obstacle to rapid and effec-

tive geographical specialization. A final factor which exerts some influence over farm price policy is the particular attitude which has prevailed and the course which has been followed when dealing with the anti-combine problem. Canada's plan of action in this connection is in some respects unique. That, however, is a whole story in itself.⁷

In the light of the foregoing it may be of interest to note the most recent declaration of price stabilization policy of the Canadian Federation of Agriculture which is the official mouthpiece of organized agriculture. In this declaration prime emphasis is placed on the need of maintaining full employment and maintaining demand abroad as well as at home.⁸ While public works are advocated as a means to this end, it is seriously suggested that prices should be supported by subsidizing low income consumers. In fact details of a possible food allotment plan are provided and the view is expressed that no other means of support would be required in the case of products consumed domestically. For those mainly dependent on the export market price floors are recommended. Such floors, however, are regarded as simply one more line of defence. The parity price concept is also accepted and a specific Canadian method of calculating parity is outlined. Of special significance is the suggestion that the government should not undertake to pay floor prices that are more than 80 percent of the parity level. The reason for this is not that the government could not afford to pay more but rather that any higher price would encourage more production than could be disposed of and thus lead to production control measures. The general idea would be that the floor price should be high enough to protect the farmer against actual cash loss. Since it would not be sufficient to cover normal overhead as well, it seems evident that the floor price is being thought of as short run protection against the extremely low prices likely to prevail during a depression or emergency period. That this list of suggestions should be forthcoming during a period when most farm prices are at or near record levels is perhaps the best possible evidence that the various existing stabilization measures are expected to have a limited life at best.

⁷ For an authoritative account of Canadian anti-combine policy see *The Control of Competition in Canada* by L. G. Reynolds, Harvard Univ. Press, 1940. Additional information may be obtained in Report of the Royal Commission on Price Spreads, published 1935 by King's Printer, Ottawa.

⁸ A complete outline of these proposals was given by the Federation's economist, Dr. E. C. Hope, at the annual convention held last January. At this convention a resolution embodying the proposals was presented to and endorsed by the delegates.

FEDERAL MARKETING AND PRICE SUPPORT LEGISLATION IN CANADA

A. H. TURNER¹

Canadian Department of Agriculture

THE vast expansion of governmental control in the economic field which has taken place during the war is without parallel in the history of the world. Nobody doubts that in the difficult period of transition that must follow immediately upon the declaration of peace, some portion, at all events, of the control must be retained but on the question of how far similar control is appropriate as a permanent peace time policy, there is acute controversy."² Professor Pigou made the above statement at the end of the First World War. Government intervention in marketing of agricultural products is not new. For many years there has been controversy over the degree to which such control is desirable. The following opinions were expressed at the annual conference of the American Farm Economics Association held at Laramie, Wyoming in August 1949.

"The only way to avoid governmental controls over agricultural production in the effort to maintain farm income in relation to the income of other groups is to find some way of eating surpluses. Falling prices have often caused production increases instead of decreases."³

"Shall we look to the government to maintain a given price structure for agriculture indefinitely without regard to conditions in the market? If so, we cannot escape giving to the Government the controls of production and sale which are needed to make such prices effective."⁴

¹ Senior Economist, Economics Division, Marketing Service, Department of Agriculture, Ottawa.

The author wishes to express his appreciation to other members of the Department of Agriculture and to C. V. Parker of the Dominion Bureau of Statistics for their assistance in preparation of this article.

The article is intended to be mainly descriptive and does not attempt to appraise or analyse the impact of the program outlined except by occasional general suggestions.

² A. C. Pigou, "Government Control in War and Peace, p. 363, *The Economic Journal*, Vol. XXVIII.

³ *New York Times*, August 17, 1949. Press release of statement made by J. W. Fichter of Ohio State Grange.

⁴ *New York Times*, August 17, 1949. Press release of statement made by Dr. O.B. Jesness, University of Minnesota.

In this setting, a discussion of Canadian marketing and price support legislation will indicate the extent to which Canada has agreed to assist agriculture through governmental legislative marketing aids and by government action designed to lessen the instability of farm product prices.

Marketing Legislation⁵

Marketing legislation in Canada has been a matter of interest and discussion for many years and more particularly since World War I. Early legislation and marketing organization was related mainly to voluntary cooperative marketing, although the first Wheat Board in Canada was established during World War I.⁶ Appropriate legislation for grading and inspection of major agricultural products became general in the 'twenties. British Columbia had entered the field of greater regulation of marketing practices in 1927 and during the nineteen-thirties most of the provinces seriously considered or actually passed milk control legislation and regulations of one kind or another.

*Agricultural Products Co-operative Marketing Act, 1939*⁷—After the Federal marketing legislation known as the Natural Products Marketing Act was declared ultra vires of the Parliament of Canada in 1937, the government of the day decided to assist orderly marketing by the encouragement of pools which would return to the producer the maximum sales return for his product less a maximum margin for handling expense agreed upon in advance.

In 1939 the Government of Canada passed the Agricultural Products Co-operative Marketing Act and the Wheat Co-operative Marketing Act. The latter has only been used in one year but the former Act, which covers the marketing of all agricultural products except wheat, has been used to a greater or lesser degree from time to time during the intervening years.

The purpose of these Acts was to aid farmers in organizing and

⁵ For further details on Agricultural Marketing Legislation up to 1939 see *Agricultural Marketing Legislation*, Marketing Service, Department of Agriculture, Ottawa, 1939.

⁶ The marketing of wheat and the operations of the Canadian Wheat Board are described in another article of this series.

⁷ For further details about this Act, see W. F. Chown, "Agricultural Products Co-operative Marketing Act," 1939, p. 5, *Economic Annalist*, Vol. XVII, No. 1, Department of Agriculture, Ottawa.

administering marketing pools for the orderly marketing of their products.

The Government would undertake to guarantee a certain minimum initial payment to the producer at the time of delivery of the product as well as a margin for handling, with sales returns being made to producers on a co-operative plan. This objective was to be accomplished under the legislation by providing for the guarantee of initial payments made for any agricultural products up to 80 percent of the average of the previous three years' prices, the exact percentage to be recommended by the Minister of Agriculture, who would enter into an Agreement with the selling agency for the product. The payment to the producer was to be made through the sales agency on a graded basis at the time of delivery of the product. It is probably correct to say that voluntary co-operative pools, as contrasted with voluntary co-operative purchase and sales agencies returning patronage refunds, were few in number in Canada in 1939. This was partly due to the difficulties which confronted the Wheat Pools during the early 'thirties, following their high initial payment on the 1929 wheat crop.

According to the Act, a co-operative plan means an agreement or an arrangement for the marketing of agricultural products which provides:

1. for equal returns to primary producers for agricultural products of like grade and quality;
2. for the return to primary producers of the proceeds of the sale of all agricultural products delivered thereunder, produced during the year, after deduction of processing, carrying and selling costs and reserves, if any;
3. for an initial payment to primary producers.

When a farmer or rancher delivers products for sale on such a basis he surrenders title to the product and acquires in exchange a fractional interest in a pool and will receive exactly the same return as other participants for the same grade and quality.

Under the Act agreements may be made by the Minister with co-operative associations, processors of agricultural products or selling agencies authorized to act for one or more co-operative associations, one or more processors or one or more associations and processors. It has been usual to make agreements with a selling agency of the latter type if one marketer does not handle a substantial portion of the product in the area.

Agreements under this Act have been made with respect to the marketing of honey, onions, potatoes, oats, barley, flax, rye, corn, fox and mink pelts and the following seeds, alfalfa, crested wheat grass, western rye grass, timothy, red clover, alsike clover, sweet clover and peas.

Initial payments approved by the Minister of Agriculture have ranged from 30 to 70 percent of the average of the last three years' prices compared to a possible 80 percent authorized under the Act.

Thus far the Government of Canada has not suffered any loss under this Act except with respect to fox pelts, which product tends to be somewhat unpredictable with respect to its annual market, due to its dependence on the whims of fashion. Serious difficulties have accompanied the marketing of fox pelts since World War II, and even though initial guaranteed advances were relatively low as a percentage of three years' prices, some loss has been sustained.

This experience indicates that any service to agriculture rendered by this Act has been at relatively small expense to the taxpayers of Canada except for small administrative expenses, which in most cases have been taken care of as part of day-to-day administration of the Department of Agriculture. No additional staff has been acquired for the specific purpose of administering this Act.

It would appear that the Act has been or is expected to be of greater service at the present time since the number of agreements under it has increased in 1948 and will likely show a further increase in 1949, based on the number of applications or expected applications by the end of August 1949. One co-operative selling agency engaged in the marketing of seeds and servicing more than a dozen local co-operatives has used the Act each year since 1939.

In administering the Act, the Minister has required that, as far as possible, products should be marketed annually or in a shorter period of time, in order that pools might be closed out promptly. However, in a number of cases, stocks have been carried over for more than one year and in such cases the Minister has usually required that definite arrangements for the marketing of stocks carried over should be made before a new agreement is completed. This question of carry-over and the length of the marketing pool may be the one which will give the greatest administrative difficulty under this Act during periods of declining price levels. The government may find itself in the difficult position of having to

hold, through a selling agency, large stocks of products while, unless a new agreement is granted, the selling agency or some other agency representing similar producers may come into the picture and finance the current year's crop without government financial assistance and at the same time compete with sales of the product being marketed under government guarantee. The government has as its safeguard against such possibility the fact that it does not pay any deficiency which may arise in the pool until after the pool has been closed out and all of the product sold. Further, the financing agency (usually a bank) becomes an interested party and it is not likely that it will consider further financing of the crop since the Minister is given some discretionary powers with respect to the termination of any agreement. The financing agency will likely try to work with the government to obtain greater security in financing and marketing of the particular products in the future.

Another problem concerns the possibility of producers' groups attempting to use the Act for the purpose of price support. The government has made it quite clear that the Act is not intended as a means of supporting prices but for assistance in financing the orderly marketing of agricultural products on a voluntary pool basis. As long as the administration of the Agricultural Products Co-operative Marketing Act and the Agricultural Prices Support Act (which is described later in this article) are as closely related within the Department of Agriculture as they are at present, this problem is not likely to occur in any significant degree.

Agricultural Products Marketing Act, 1949—With the enactment of marketing Acts in most provinces, after the Natural Products Marketing Act, 1934 had been declared ultra vires of the powers of the Government of Canada, and the development of provincial boards and schemes under these Acts, as well as government export boards in wartime, little or no further pressure was placed on the Government of Canada to pass further marketing legislation of this type until after World War II. During the war years the government, with the cooperation of producers and trade organizations, handled the marketing of the main agricultural products under a system of wartime boards set up to direct the production and allocation of products, to handle export contracts, and to control prices.

As soon as World War II was over and government boards and controls began to disappear, producer groups again began urging

federal legislation with respect to organized marketing. Some of the wartime export boards have been continued and are still operating in the post-war period, under the authority of the Agricultural Products Act 1947, with the main purpose of handling and ensuring fulfilment of export contracts with other governments. This Act expires March 31, 1950. Depending on the basis of new export contracts the Government may at that time expect producers and the trade to have developed the necessary marketing organization to operate on their own behalf with the assistance of the agricultural marketing legislation which already exists.³ The Agricultural Products Marketing Act was passed in April 1949 and provided as follows:

"The Governor in Council may by order grant authority to any board or agency authorized under the law of any province to exercise powers of regulation in relation to the marketing of any agricultural product locally within the province, to regulate the marketing of such agricultural product outside the province in interprovincial and export trade and for such purpose to exercise all or any powers like the powers exercisable by such board or agency in relation to the marketing of such agricultural product locally within the province."

In this way it is possible through marketing boards to provide producer groups within a province with complete marketing control over any commodity produced in that province. This of course assumes that such producer groups desire this control and can have their scheme approved by their own province.

For example, if the poultry producers of Alberta wish to effectively control the marketing within the province of all or part of the eggs produced within Alberta, a board set up under the authority of its own provincial statutes could do so. By an application under the Agricultural Products Marketing Act, 1949, such Board could obtain an extension of its powers to give it complete control over the marketing outside of the province of all or part of the product produced within the province.

The Agricultural Products Marketing Act, 1949, does not give the local marketing board any greater control over agencies outside the province than is possible through the control of the commodity by the board and whatever contractual arrangements it may make

³ The long term marketing policy for grains, which is likely to remain under government control boards, is described in another article in this series.

with such agencies outside the province. However, it does give the board authority to take action or police those producing the product within the province and require them to handle the product in a certain manner when marketing outside the province.

Legal opinion suggests that this is about the limit of the authority of the Government of Canada to regulate marketing under the present Canadian constitution, unless it wishes to engage in the purchase and sale of the product.

To date the Governor-in-Council has extended certain specific powers bestowed upon the British Columbia Fruit Board and the Nova Scotia Marketing Board with respect to apples by their respective provincial legislatures. It is likely by the time this is read that the British Columbia Coast Vegetable Marketing Board will also have had approval of an extension of certain of its powers.

The Province of Ontario has a number of control schemes under its marketing Act, but it is doubtful if any extension of powers that would be of assistance is possible here, in most cases, since the boards set up in Ontario do not usually take actual control of the commodity. These Ontario boards simply arrange prices and other marketing practices by negotiation with the trade and make it illegal for the product to be handled otherwise within the province. It is doubtful that an extension of power to control producers shipping outside of the province could be enforced in a satisfactory manner, if a provincial marketing board does not offer to purchase, directly or through agents, the supply of the product which it wishes to control.

While the legislation is new, the general idea as has been noted above is anything but new. By providing this legislation, the Government of Canada has made it possible for producers to organize themselves into large scale selling and market control units, providing sufficient numbers agree voluntarily that this is the best scheme of marketing and that they meet the various other requirements laid down by the provincial legislatures.

Organized marketing boards of this type could make it possible for the Agricultural Prices Support Board, whose functions are described briefly later in this article, to render more effective assistance to agriculture. This would be possible since such Boards would provide a means whereby the Agricultural Prices Support Board may be approached when the need arises and also would be

helpful in handling any price support program where the deficiency payment method is used. A producers' board of this type would reduce to a minimum the amount of auditing and marketing supervision that would be necessary under a system of deficiency payments by the Board to producers. The producers' board would be interested in obtaining the best price possible for the product, even above that guaranteed by the Government, if at all possible, and thus would be working in the interest of the people generally by lowering any costs to the Government for assistance under price support programs.

Price Support Legislation

The objective of minimizing the effect of farm price fluctuations is not a post-war development in Canada. Assistance to agriculture has included many kinds of payments to aid in marketing, to give incentives for increasing or decreasing production, to help pay transportation costs and to provide price premiums for better quality products. Most of these federal schemes of price or income assistance have meant the voting by Parliament of special appropriations, or the enactment of continuing legislation relating to payments and special assistance for a particular commodity.

Canadian farmers are dependent on export trade. Any attempt to maintain their income at a relatively high level requires maintaining exports at 20 to 40 percent of agricultural production. Prices of agricultural products that enter international trade are highly sensitive to changes in foreign demand and monetary and other conditions affecting exchange rates. During the war, overseas contracts played a prominent part in Canadian agricultural price stabilization. A number of the government boards set up during wartime to carry out these contracts along with the necessary export and import controls have been continued in the post-war period under the authority of the Agricultural Products Act, 1947. Overseas contracts for agricultural products in 1949 (with the exception of grains) still handled by Government boards whose authority rests in the Agricultural Products Act, 1947, include those for bacon, cheese and eggs.

Agricultural Prices Support Act, 1944.—The Agricultural Prices Support Act was passed by Parliament in 1944 and represents a general legislative enactment to which producers of any agricultural commodity, except wheat, may turn if need for price assist-

ance can be established. At the present this Act is operative until March 31, 1950.

The administration of the Act is placed in the hands of a three-man Board, the chairman of which is an official of the Canadian Department of Agriculture, while the other two are representatives of Canadian agriculture. The Board has at its disposal a revolving fund of \$200,000,000. which is maintained at that amount by annual appropriations, if there is any loss during the year, and, if there is any surplus, it is turned over to the Consolidated Revenue Fund annually. The Board is "to endeavour to ensure adequate and stable returns for agriculture by promoting orderly adjustment from war to peace conditions and to endeavour to secure a fair relationship between the returns from agriculture and those from other occupations."

Unlike price support legislation in the United States, there is no historical price formula set out in the Act. The decisions as to the levels at which prices are to be maintained or the commodities whose prices are to be supported are left to the Board to recommend to the Government. In other words, there is nothing automatic about the Act and its application. However, it provides that the Board may recommend price support for any agricultural commodity, except wheat, which may be designated by the Governor-in-Council, including processed meat, dairy and poultry products.

The usual procedure is for representatives of the interested commodity group to make representations to the Board and after the Board has studied the situation and considered the need it will recommend to the Government that assistance be given or reject the application. It will also recommend, if the application is accepted, the prescribed price and the amount of assistance as well as the method of giving the support which it considers most feasible in the particular case. If the Government approves, then the support program will be put into effect by the Board.

In carrying out this procedure the Board usually takes into consideration:

1. Historical price patterns for the commodity concerned and price levels at which related commodities, if any, are being supported.
2. The basic cause of the price or income decline and the supply of the commodity.
3. The long term market possibilities for the product.
4. The problems of storage and disposal likely to be involved.
5. The relative efficiency of the producers concerned along with possible

alternative sources of income as well as the number of producers affected.

6. The implication of the precedents which are being established.

The Board, as a rule, prefers to have and may request the commodity group itself to suggest solutions to the problem on a long term basis. The ability and willingness of such group to carry out the suggested solutions is regularly appraised by the Board in considering its recommendation.

With this flexibility of operation, it is possible to use a variety of approaches with respect to solving the marketing problems relating to the different products that may require to be supported.

The Board can recommend assistance or support by either of two methods, in accordance with the Act:

1. Outright purchase.
2. Underwriting the market through guarantees or deficiency payments.

The latter method has been used to date only where marketing boards with experience in handling the commodity have been established by the commodity group concerned.

While outright purchase has been the general policy, there have been a number of variations in approaching such purchase, including the following:

- (a) An offer to purchase all of the commodity as produced and offered at a price fixed in advance of production.
- (b) An offer to purchase up to a limited quantity of the product and thus relieve the market of the surplus until a price adjustment takes place. This may involve the Board undertaking to withhold from the market the purchased portion of the commodity, at least temporarily.
- (c) The purchase of all offers of the commodity already produced between specified dates, usually towards the close of the marketing year.
- (d) The purchase of an additional quantity of a product for a buyer's account in order that a sufficient total quantity to relieve the surplus situation in the market may be removed, even though the buyer may obtain a bargain through receiving a larger quantity of the product at a discount price.

For the most part, the Board has not offered an overall price support program which would accept the product as produced for market, butter and cheese being the two exceptions. In the case of butter, the Board was continuing a policy which had been established earlier under wartime regulations and was also dealing with

a product which is normally consumed in its entirety in the domestic market. Temporary marketing adjustments, due to a previous short supply situation in butter and the introduction of margarine for the Canadian consumer with the uncertainties created seemed to require some stabilizing factor to protect the producer against extreme price fluctuations. In the case of cheese, a floor price was fixed in advance to December 31, 1949, in lieu of a Government commitment to purchase cheese throughout the 1949 cheese marketing year, in order to fill the contract with the United Kingdom. The cheese contract was filled earlier than anticipated and the Government has fulfilled its commitment by arranging for the Agricultural Prices Support Board to continue to purchase any cheese offered at the contract prices for the balance of 1949.

The Agricultural Prices Support Act, although passed in 1944, did not become operative until 1946. Since that time its operations have included assistance to a number of products under varying circumstances and at different periods of time.

Potatoes—In 1946 and 1948 assistance was given to the potato industry at a cost to the Government of approximately \$170,000 in 1946 and \$1,600,000 in 1948. In 1946, sales to the British Ministry of Food after the price support program had been established, relieved the market to a sufficient extent to require the Government to accept only a slight loss on the purchase of potatoes for re-sale to processing plants. These potatoes were purchased at \$1.50 for a 165-pound barrel (91¢ per 100 lb.) for field run potatoes containing at least 70 percent Canada No. 1 grade for re-sale to starch processing plants at \$1.00 per barrel (61¢ per 100 lb.). In 1948 the program was based on the purchase of potatoes in designated areas in the Maritime Provinces at \$1.15 per hundred pounds for Canada No. 1 grade potatoes held on farms after April 1, 1949, and no applications for purchase to be accepted after May 31, 1949. Less than three percent of the 1948 production of potatoes in Canada were purchased under this program, and towards the end of the purchase period, prices firmed in the market and the Government was able to re-sell some potatoes to the producers for the same price which they had received. In both years the support program was applicable only in certain parts of the Maritime Provinces, where the removal of some commercial surpluses stabilized the Canadian market generally.

Apples—In 1947, 1948 and 1949, the Agricultural Prices Support Board extended assistance to the apple growers in Nova Scotia and in 1948 and 1949 to the apple growers in British Columbia. For many years prior to the war, Nova Scotia apple growers had been shipping the bulk of their crop to the United Kingdom. This market was lost to them on account of the war and the Government has given some assistance in practically

every year since 1939, although it was not until 1947 that the Agricultural Prices Support Board entered this picture. In 1947 and 1948 the method of support consisted of a system of guaranteed prices, with the payment of any deficiency to the marketing boards in the provinces concerned being made after the apple marketing season was completed. In 1949 the Agricultural Prices Support Board has purchased through the British Food Mission in Canada an additional quantity of apples which it has given to the British Ministry of Food on a dollar for dollar basis up to a total amount of \$1,500,000. The apple price support program in 1947 cost approximately \$3,000,000 while that of 1948 cost in the neighbourhood of \$1,500,000, with most of the direct assistance going to Nova Scotia apple growers in each year. Indirect benefits of the program were received by all apple growers in Canada due to the support given surplus production areas.

Dried White Beans—In order to assist the growers of the 1948 crop of dried white beans, the Government, through the Agricultural Prices Support Board, purchased about 40,000 bushels of beans for refugee relief at a price of \$3.75 per bushel delivered to bean warehouses, plus necessary cost for processing, grading, bagging, loading, inland and ocean freight charges, at a cost of approximately \$195,000. In establishing this support program, a maximum limit of expenditure of \$200,000 was set. The Bean Growers Marketing Board of Ontario was successful in selling the balance of the product in the domestic or export markets.

Extracted Honey—In order to relieve a surplus resulting from a high production per hive in 1948 and the fact that overseas markets had not been regained for Canadian honey in the post-war period, the Board agreed to purchase up to 5,000,000 pounds out of a total production of 45,000,000 pounds of 1948 honey, offers to be accepted from May 15 to July 31, 1949. The Board actually received offers of only about 3,000,000 pounds, which it purchased at a cost of approximately \$350,000. Up to September 15, 1949, distribution and sales policy was limited to providing price quotations on request for quantities which could be exported from Canada.

Butter—On April 1, 1949, the Agricultural Prices Support Board offered to purchase butter produced in Canada at prices ranging between 57½¢ and 59¢ per pound for first grade butter, at various delivery points. By the end of August 1949, the Government had purchased in the neighborhood of 45,000,000 pounds of butter. During August the position had become sufficiently clear for the Board to announce a general price policy up to March 31, 1950. The selling price during the present support period, which ends on March 31, 1950, will not be less than cost plus storage charges. As soon as the Government announced this policy, the trade began to enter the market and make their own purchases and store some butter. However the Board will have most of the available butter to distribute during the short supply winter months.

Dry Skimmed Milk—In May, 1949 the Board announced a purchase program for first grade dry skimmed milk up to a maximum expenditure of \$1,000,000, prices to be 9.5¢ per pound for roller process and 10.75¢ per pound for spray process powder, f o b. country points. The Government

purchased the maximum amount under this program and still held the skim milk powder at September 15, 1949, although it is expected to transfer it for foreign relief purposes or sell it in export markets, in the near future.

Cheddar Cheese—On August 24, 1949, the Government announced that the Agricultural Prices Support Board would continue to purchase cheddar cheese produced in Ontario and Quebec on and after August 1, 1949, on a similar basis to that on which the purchase of cheese for the British Ministry of Food had been carried on up until that time, at a price ranging from 29¢ to 30¢ per pound for various grades, f o.b. factory.

Up until March 31, 1949, the operations of the Board had cost the Government of Canada approximately five million dollars including administrative expenses as compared with a total income from the 1946-48 production of all Canadian farm products of approximately six billion dollars.

Throughout its operations, the Board, as far as possible, has anticipated probable needs by studying situations that would appear likely to lead to requests for action. The staff of the Economics Division of the Department of Agriculture, assisted by personnel provided by the Board, has been requested to study production and marketing trends and to keep the price situation under constant review. When actual operations begin, the commodity divisions of the Department of Agriculture are the active agents of the Board in carrying out the purchase programs. To date the Board has not had large scale distribution and merchandising problems to handle, but with the approaching distribution problem for butter, such policies will have to be developed. As a start the Board has acquired the services of a distribution manager who in the first instance will work closely with the commodity divisions of the Department of Agriculture and other Departments of the Government as well as with the trade.

"There is pretty general agreement that the operations of the Board to date have been quite successful. Prices of commodities dealt with have been stabilized and producers have been able to market their products without the serious price declines that threatened. The stability ensured by purchase programs and guarantees has permitted the trade to purchase with confidence and there is evidence that where declining prices had already resulted in delayed purchases, products have moved freely to market once a stabilized price was obtained.

"It is understood that the Board has not encountered any serious

difficulties that may be directly attributed to its method of operation or to the Act itself. It has experienced the kind of problems that are likely to be associated with any stabilization program involving purchases of products. To what grade or class of product should support be offered in order to have the desired effect on the total volume of the product? Will a program applied to a highly specialized surplus producing area have the desired effect on prices elsewhere? Should products from areas where support is in effect be marketed in competition with those of non-support areas, and how? Should an expensive by-product processing program be undertaken in order to preserve products when there is little or no chance of recovering the financial outlay or when it is difficult, if not impossible, even to give the by-product away?"⁹

With respect to the termination of the Act, most people will agree that the idea of stipulating the transition period in the Act was to provide against the maladjustment between the primary producer and other industries which historically has occurred in the first few years following wartime inflation.

"What the Act really visualizes is the possibility of marketing difficulties and the need for adjustment in supplies of different products rather than the complete absence of markets. The Act recognizes, in short, a national obligation to use the resources of the entire country to maintain price stability for agriculture during a period when most of the economic improvement of recent years could be wiped out by causes completely beyond the control of farmers. I think we all recognize now, that even though major nations are bending their energies toward building a stable post-war economy, there is no certainty of immediate success and, therefore, each nation must guard the position of its own people, while making every possible contribution toward developing sound international relationships."¹⁰

As to the future, contracts in some form or other will likely continue to take a prominent part in any Canadian agricultural price stabilization program, even though they may or may not be carried

⁹ These quotations have been taken from an address delivered by Dr. J. F. Booth, Associate Director of Marketing Service, Dominion Department of Agriculture, on June 21, 1949, at the 1949 annual meeting of the Canadian Agricultural Economics Society.

¹⁰ This statement was made by J. G. Taggart, now Deputy Minister of Agriculture and at the time Chairman of the Agricultural Prices Support Board, at the 1946 annual meeting of the International Association of Milk Control Agencies in Montreal.

through by a system of Government boards as they have been during wartime and in the immediate post-war period. Uncertainty in the export field due to exchange problems, along with general recognition that agriculture should receive some assistance to protect it from price and marketing catastrophes, make it appear likely that the Government will extend the Agricultural Prices Support Act beyond its present expiration date.

Conclusion

There exists considerable legislation in Canada on a federal and provincial basis, which gives governmental agencies and farmers the power to take measures for controlling the marketing of farm products. These include provincial marketing and milk control legislation, the Agricultural Products Co-operative Marketing Act and the recently passed Agricultural Products Marketing Act, the latter two being described in this article. This legislation was primarily to provide for orderly marketing techniques rather than price support measures.

Canada has also, through legislation and in other ways, given other marketing aids such as those related to research, education, information, inspection, grading and many other service measures of this type designed to assist in correcting the maladjustments within agriculture and between agriculture and the rest of the economy.

Finally, Canada has passed legislation that combines marketing with provisions for minimum prices for farm products. This includes the Agricultural Prices Support Act, the Canadian Wheat Board Act and the Agricultural Products Act, the first of which has been described in some detail in this article. The overall purpose of this legislation is to reduce price instability and indirectly to have a steadying influence on farm income.

The current agricultural prices support program for all farm products is of an ad hoc nature (full consideration for each product at the time of discussion) contrasted with the use of a parity or some other formula. The price offered by the Board is not necessarily the current market price. The advantage of this procedure is that it allows for a price decision for each commodity on the basis of the current domestic and export position and gives the Board a greater scope in arriving at the immediate support price level. A disadvantage from the farmers' point of view may be that it does not in all

cases provide a forward price which might be helpful in guiding farmers in their production plans.

"Every farmer would like to have 90 percent support and no controls if he thought it could go on forever and there would never be a day of reckoning, but it won't go on and it can't go on because, by the very nature of things, high rigid agricultural prices become in themselves incentives to production. In these days when prices of agricultural products and levels of agricultural supports seem to be of overwhelming interest, we may remember that price is only one of the parts and sometimes one of the least significant parts of a real national program for the long-range welfare of the farmers of this land."¹¹

Canada is trying to meet its general agricultural marketing and price problems by means of legislation such as that described in this article, since it would appear that in the long run agriculture in Canada needs assistance in:

1. Shifting production from time to time to conform with export demand so that an adequate volume of exportable products may be maintained.
2. Maintaining production facilities for certain commodities during temporary periods of marketing difficulties.
3. Providing some program of assistance to supplement general government policy during periods of depression.

EXPERIENCE WITH PROVINCIAL MARKETING SCHEMES IN CANADA

M. W. FARRELL
Ontario Agricultural College

THE provincial governments of Canada have been experimenting with marketing boards and schemes to an increasing degree since British Columbia first passed "The Produce Marketing Act" in 1927. The general objective has been the supplementing of free market pricing by government sponsored boards of grower representatives under a provincial marketing commissioner. For some products the desire for higher farm incomes from "orderly marketing" within the year has been the motive. For other products, the farm groups have sought higher prices through compulsory bargaining and arbitration between representatives of the numerous farmers, and representatives of the relatively few processors or distributors who were presumed to have monopolistic powers of bargaining, and were allegedly taking abnormal profits. Through boards set up under the laws of the province with powers of compulsory arbitration, farm producers have sought to bring their own members into line, and to bargain collectively with the distributors or processors who were a bottleneck link with the consuming public. At the request of a group of producers who wish to market their products through a marketing scheme, a poll is conducted by the provincial department of agriculture. If the poll shows a majority of at least two-thirds in its favour, the scheme is proclaimed and all producers of the product concerned are thereupon compelled to comply with its terms. The chairman of the schemes has been the marketing commissioner who heads up a board of farmer members representative of the major producing areas. This board bargains with the representatives of the processors or distributors of the product, and in the case of a dispute can refer it to a governmental arbitration board which makes a decision binding to both parties. Minimum prices may be set, and the channels, quantities and qualities of marketings laid down. In many respects this procedure is peculiar to the Canadian provinces.

General History and Background

The first marketing act of the British Columbia legislature followed a four year period of low and erratic prices for tree fruits,

and declining support for the voluntary co-operative which was handling the bulk of tree fruit sales. Under the Act, minimum prices were set and the rates of marketing prescribed. Levies were imposed on the producers to cover the costs of operation of the board. This Act was ruled unconstitutional in 1931 on the ground that it sought to regulate interprovincial trade, a Federal Government responsibility. A companion act, "An Act for the Relief of Dairy Farmers, 1929," was ruled unconstitutional in 1932 because the equalization fees on the producers of milk in the Lower Fraser Valley were held to be indirect taxes, and hence beyond the taxing powers of the provincial governments. When the Federal Government passed the Natural Products Marketing Act in 1934, British Columbia immediately passed a provincial Natural Products Marketing Act in the belief that powers not resident in the Federal Government would *ipso facto* be covered by the provincial legislation. In the years 1934 and 1935, marketing boards were established in most provinces under the federal act. British Columbia and Ontario participated to a greater degree than the other provinces, and since 1935, have proceeded with provincial marketing boards with aims similar to those embodied in the federal legislation. Nova Scotia has put into effect schemes covering apples and wool under an act of 1946. Alberta has an act of regulatory features covering poultry marketing. Saskatchewan possesses similar legislation but it has not been put into effect. This brief survey of the background of the marketing boards indicates their gradual development in the Canadian provinces.

In many respects the agricultural commodity groups participating in marketing boards resemble the organized labour unions in their regional collective bargaining. Whereas labour unions must expand their membership by persuasion, the operation of schemes is commenced by a two-thirds vote of approval by the farmers, most of whom may be largely passive to the objectives of their leaders.¹ The compulsory fees on each unit of product sold by the farmers compare with the compulsory check-off of the unions, while the compulsory arbitration by government represents more than the mediation services provided by the Departments of Labour. The processors under the marketing boards can decide how much of

¹ This is the administrative policy, rather than the legal requirement. *Vide* speech of Mr G. F. Perkins, Chairman, Farm Products Marketing Board of Ontario, March 14, 1949. No legal requirement is stated in the British Columbia Act.

the product they will buy, just as the employers of labour agree to the wage rates and other conditions, and then hire the number of labourers which they regard as most profitable to their business. The similarities to labour unions are very pronounced.

The Dominion Natural Products Marketing Act

During the fifteen years preceding the Natural Products Marketing Act of 1934, farm prices and incomes had fallen severely in a nation heavily dependent on the exports of primary products. Not only had farm incomes declined from 1920 to 1922, but the recovery in raw materials prices to 1929 had been modest. The depression began in 1929 and from then until 1933 intensified. Farmers looked for some means or other of resisting the fall in their incomes and turned to marketing adjustments, as United States had done under the Federal Farm Board in 1929 to 1931, and as British Columbia had attempted to do in 1927 to 1932. During the 1920's, and especially from 1927 to 1929, Canada had undergone a burst of consolidation in its food products industries. Canadian Canners had absorbed many small canning companies; Canada Packers was formed as a holding company in 1927; Western Canada feared the Nash combination which was dominant in the sale of fresh fruits and vegetables in the four western provinces. In part these consolidations represented larger firms absorbing the smaller ones which had excess capacity, but farmers were suspicious of the reduced number of buyers for their products. British Columbia had already experimented with marketing controls which established bilateral bargaining of the farmers' selling monopoly and the processors' or distributors' group. The Royal Commission on Mass Buying and Price Spreads in its hearings in 1934 had publicized certain aspects of large-scale buying which convinced farmers that the incidence of the depression was falling with undue severity on the prices of their raw products. For reasons such as these, Canadian agriculture supported the passage of the Natural Products Marketing Act by the government of Canada in 1934. This legislation applied to interprovincial and export trade. On the whole the farm groups which took advantage of the Act were already organized, the least depressed, and in small contiguous areas. British Columbia raw material producers took greatest advantage of the Act. The following schemes serve as illustrations: British Columbia Tree Fruit, British Columbia Red Cedar Shingle, British Columbia Dry Salt

Herring and Dry Salt Salmon, Milk Marketing of the Lower Mainland of British Columbia, British Columbia (Interior) Vegetable Marketing, British Columbia Coast Vegetable Marketing, British Columbia Halibut Marketing, British Columbia Hot-house Tomato and Cucumber Marketing, British Columbia Small Fruits and Rhubarb Marketing and the British Columbia Sheep Breeders' Marketing Scheme.² Ontario producer groups covered by the Natural Products Marketing Act included Ontario Flue-Cured Tobacco, Western Ontario Beans, Ontario Cheese Patrons and Ontario Burley Tobacco. Certain schemes cut across provinces such as the Fruit Export Marketing, Eastern Canada Potato Marketing, Canada Jam Marketing, Processed Berry Marketing, Dairy Products Marketing Equalization, and the Butter Export Stabilization schemes. The only purely Maritime Scheme was the Grand Manan Smoked Herring Products of New Brunswick. The export schemes (dairy products and butter) attained very little experience.

The boards administering the schemes were allowed to advise on tariff policy. They had powers to regulate marketing, to establish pools, and to levy license and equalization fees on processors and farm producers. It will be observed that the schemes were heavily weighted by British Columbia products which were produced in clearly defined, semi-isolated agricultural districts, where bottlenecks existed in processing or packing establishments, or in transportation outlets. The Ontario and Grand Manan schemes also applied to clearly defined areas in the case of beans, burley tobacco, flue-cured tobacco, and smoked herrings.

As an illustration of the setting of the time of marketing, the British Columbia Tree Fruit Scheme authorized the monthly release of apples. The places of marketing were prescribed in the Ontario Cheese Patrons Marketing Scheme. All cheese was to be sold at auction on local cheese boards in order to ensure a greater degree of competition between the buyers of the product. The quantity of product marketed was prescribed under the British Columbia Salt Fish and Red Shingles Marketing Schemes. Minimum grades were set under the British Columbia Tree Fruits and Eastern Canada Potato Marketing Schemes. The method of distribution was determined in part by the Eastern Canada Potato

Marketing Scheme where sales on consignment by dealers were forbidden. Tolls on sales were generally collected when the product was received by the distributors or processors. Regional representative boards operated within the limits prescribed by the Dominion Marketing Board.

The legality of the Natural Products Marketing Act under the British North America Act of 1867³ was referred to the Supreme Court of Canada in November, 1935. After that date no further boards or schemes were established, and in effect the Act came to an end. In June 1936 the Supreme Court of Canada ruled that the Act was unconstitutional (*ultra vires* of the Federal Government). In January 1937 the Legal Committee of the Privy Council in the United Kingdom, the highest legal authority on constitutional matters, upheld the Supreme Court of Canada's decision, and as a result the boards established under the Natural Products Marketing Act were disbanded.

The Provincial Boards and Schemes

British Columbia's Natural Products Marketing Act of 1934 continued in force, and in a reference to the Supreme Court of Canada in November 1938 was held to be within the powers of the provincial government. Certain schemes have been continued in British Columbia under this act, notably the British Columbia Tree Fruit Marketing Scheme, the British Columbia Coast Vegetable Scheme, and the British Columbia Interior Vegetable Scheme. In Ontario the Farm Products Control Act was passed in March 1937 to allow marketing schemes to continue under provincial authority in that province. Almost immediately the Ontario Cheese Producers' Marketing Scheme was put into effect. Shortly afterwards the asparagus, pear, plum, cherry, and peach growers came under schemes for that part of their crops which went into processing. Significantly the Ontario Flue-Cured Tobacco Growers and the Ontario Burley Tobacco Growers did not set up schemes under the new provincial legislation. Instead they incorporated themselves under the Ontario Companies Act, and have handled their own price negotiations, acreage allocations, and marketings of tobacco ever since.

³ The British North America Act of 1867 incorporated Canada as a federal union. The powers of the provinces were listed, with remaining powers to the federal government. Judicial decisions have further defined the powers, and established precedents.

The Ontario products now covered by marketing schemes include the following annual crops: tomatoes, peas, green and wax beans, sweet corn, beets, carrots and cabbage for processing, dry field beans, seed corn, soya beans, new potatoes and sugar beets. Raspberries and strawberries for processing are representative of short run crops. Asparagus, peaches, pears, cherries, plums and grapes for processing represent perennial crops. The other products covered are cheese, hogs and cream. The dates of introduction of the schemes indicate that since 1944 the boards have expanded considerably. The schemes in force in mid-1949 are:

- The Ontario Cheese Producers' Marketing Scheme, 1938
- The Ontario Asparagus Growers' Marketing Scheme, 1938
- The Ontario Pear, Plum, and Cherry Growers' Marketing Scheme, 1938
- The Ontario Peach Growers' Marketing Scheme, 1938
- The Ontario Sugar Beet Growers' Marketing Scheme, 1942
- The Ontario Seed Corn Growers' Marketing Scheme, 1944
- The Ontario Berry Growers' Marketing Scheme, 1944
- The Ontario Bean Growers' Marketing Scheme, 1944
- The Ontario Vegetable Growers' Marketing Scheme, 1946
- The Ontario Hog Producers' Marketing Scheme, 1946
- The Ontario Cream Producers' Marketing Scheme, 1947
- The Ontario Grape Growers' Marketing Scheme, 1947
- The South-Western Ontario New-Potato-Growers' Marketing Scheme, 1948
- The Ontario Soya Bean Growers' Marketing Scheme, 1949

As previously indicated, provincial marketing acts have been passed in Alberta, Saskatchewan, Nova Scotia and New Brunswick. Alberta has instituted a poultry marketing board, but its powers have been purely regulatory with a view to improving the quality of poultry and eggs. New Brunswick's Act has not extended beyond the continuation of the Grand Manan Smoked Herring Products scheme. The degree of use of marketing legislation varies considerably within Canada.

General Powers of the Boards

Under the marketing boards, as presently constituted, the usual procedure is to set up provincial boards and to establish districts with representatives from each district on the provincial board. The provincial boards can establish local boards which serve in an advisory role. The boards have power to investigate, arbitrate, adjudicate upon, adjust or otherwise settle any dispute between pro-

ducers, processors, distributors or transporters of farm products, or between any two such classes of persons. They may investigate the cost of producing, processing, distributing and transporting any farm product, prices, price-spreads, trade practices, methods of financing, management, grading, policies and other matters relating to the marketing of farm products. They may do such acts and make such orders and directions as are necessary to enforce the observance and carrying out of the provisions of the Act, the regulations, and any scheme. They may establish price negotiating agencies for any scheme and adopt or determine fair or minimum prices for any regulated product, or any grade of a registered product. They may exempt from any scheme or any order or direction of the Board, any person or class of persons engaged in the producing or marketing of any regulated product or any class, variety or grade of regulated product. They may require persons engaged in the producing or marketing of a regulated product to register their names, addresses and occupations with the Board; require such persons to furnish such information in regard to the regulated product as the Board may determine, and inspect the books and premises of such persons. They may require the furnishing of security or proof of financial responsibility by any person engaged in marketing a regulated product. They may refuse to grant any license for any reason which the Board may deem sufficient. Persons may be prohibited from engaging in the marketing or processing of any farm product except under the authority of a license issued by the Board. The Board may suspend, revoke or refuse to renew any license for failure to observe, perform, or carry out any of the provisions of the Act, and the regulations of any scheme, or any order or direction of the Board. In every case the applicant shall be afforded an opportunity of appearing before the Board to show cause why such license should not be suspended or revoked or why such renewal should not be refused. The Board may, by such means as it may deem proper, stimulate, increase or improve the marketing of farm products. The commodity boards may require the licensing of persons engaged in marketing or processing, and may prescribe the license and equalization fees. They have the power to collect, use and return service charges or equalization fees on farm products. Under the British Columbia Act, loans may be granted to assist the construction of storage facilities. A feature of the British Columbia boards is their emphasis upon having all sales go across one desk to the distribu-

tors, together with a pooling of sales throughout the season. These powers are substantially similar in all provincial acts, but the extent of use varies greatly between provinces.

In practice the license fees on processors or distributors have been purely nominal. The administrators have been guided by the experience of the Act for the Relief of Dairy Farmers (British Columbia) where the license fees were held to constitute indirect taxation and to be *ultra vires* of provincial authority. Moreover, the Agricultural Adjustments Act of the United States had been thrown out in 1936 on the issue of processing taxes. By negligible processors' fees, the provincial Marketing Acts in Canada are not liable to such a judicial reverse. The fees collected under provincial acts have come from farm producers, although they are deducted by the processors. The following fees collected in Ontario in 1948 or in the 1949 schemes authorized to date may serve as illustrations:

cheese—5 cents per hundredweight of cheese
hogs—2 cents a carcass
peaches for processing—40 cents a ton
cream—1/10 of a cent per pound of butterfat
sugar beets—3 cents per ton delivered to processor
South-Western Ontario new potatoes—1 cent per 75 pound bag
berries for processing—1/10 of a cent per quart
beans—2 cents per bushel license fee
38 cents per bushel equalization fee
asparagus for processing— $\frac{1}{2}$ cent per pound
seed corn—2 cents per bushel
soya beans— $\frac{1}{2}$ cent per bushel.

General Appraisal of the Schemes: Their Value and Significance

Since the marketing boards and schemes are in force in several of the Canadian provinces, and are supported to some extent by the three major political parties of Canada, it is appropriate to examine their objectives and their administration. Already Ontario and British Columbia have had over a decade of experience. Ontario will be used as the main illustration.

1. Many schemes were launched out of the conviction that price gains could be secured if some intermediate bargaining agency could be set up between the numerous farm producers and the few buyers or processors. Especially if there was one dominant buyer, the small sellers and their local agents could, through organization, avoid taking a low price or a narrow margin for their produce.

For the monopoly buyer, there is undoubtedly an upper limit to the price that he will pay, and a lower price at which farm producers may be induced to sell. The margin which is the monopoly gain to the buyer is something that the sellers may be able to extract under pressure. The sellers may also feel that their centralized board can carry price determination out from the consuming or processing centres to the production areas. Perhaps some gains in price have been attained for producers by their consolidation under a marketing board. They might equally well be attained through a selling co-operative. Certainly our city labourers have felt impelled to form their trade unions for similar reasons so that the buyer of labour service might be faced by one selling agency rather than hundreds or thousands of freely competing labourers. On the other hand it may be impossible for a central selling agency to attain any gains through such bargaining. If there are a few large buyers of farm produce, each one anxious to maintain his share of the market, and each determined not to let the others get a price advantage (and a profit opportunity) by buying cheaply in one or more local markets, then the market prices will approximate the competitive level. Surely this situation is fairly typical, and since it is general, the gains from bilateral bargaining are probably very slight in many cases, and the cost of operating the boards may be a clear deduction from the income that farmers would receive, especially during sellers' markets and rising prices, as in the period since 1941.⁴

2. Frequently the argument is raised that the marketing schemes are the essence of democracy as the individual farmers can vote a scheme into effect, or can vote its termination. In fact most Ontario schemes have been inaugurated by wide majorities. It should be remembered, however, that a majority of a commodity group is almost inevitably a minority of all farmers and inevitably a minority of the total population. There is no guarantee that producers are acting in the public interest, or in the consumer interest through the price policy of the schemes. The most that can be said is that democracy exists within the group itself. Moreover, the marketing acts do not contain specific provisions for the re-polling of producers to ascertain if the schemes have a continuous broad base of support. This would seem to be a large oversight.

⁴ *Vide* W. Baum, *Pricing in the Tobacco Auction*, Proceedings of the Annual Meeting of the New England Research Council on Marketing and Food Supply, April 14-15, 1949.

3. To some extent the operation of marketing schemes in Ontario has encouraged cost studies of labour, equipment and material inputs into crop production. Certainly cost and farm management studies were conducted previously, notably in fluid milk production, but to assist in price negotiations producer groups have asked for and received assistance in cost studies of canning corn, peas and tomatoes. To some extent the changes in costs are considered when bargaining for contract prices, while the farmer's cost position has encouraged him to examine his production practices. This has contributed to improvements in farm management, and as such is highly welcome.

4. A third aspect of the marketing schemes has been the extent to which the contract prices have served as forward prices. For certain of the schemes, notably cheese, cream and hogs, no effort has been made to implement forward prices. For annual crops such as sweet corn, peas, beans, and tomatoes, the floor prices are generally determined between January and the middle of March, in time to influence plantings. In 1949, however, disputes over prices and related conditions led to deadlocks between producers and processors, and the price which came out of the arbitration proceedings left little time for adjusting farm plans. The floor prices for the season have provided a measure of price assurance to farmers, and the opportunity to balance the income alternatives of one crop against another. For tree fruits such as cherries, plums and peaches, the price negotiations await knowledge of crop conditions. For Ontario new potatoes, and British Columbia fresh vegetables, returns are calculated on the basis of the receipts from pooled sales. In such cases, the prices represent bargaining alone, with no opportunity to alter annual production. On the criterion of forward pricing, the marketing boards have had a somewhat irregular record.

5. The required conditions for the institution of a marketing scheme in Ontario suggest limitations to their application and usefulness. In the Report of the Minister of Agriculture (Ontario) for 1944 three considerations were mentioned in the establishment of a scheme. First, each proposed scheme had to set out a practical marketing problem. Second, the marketing of the crop had to be subject to effective regulation under the limitations of provincial jurisdiction. Third, if the first two conditions were met, a ballot of the growers was to be conducted to determine whether the majority were in favour of the scheme. In practice these conditions have meant that the schemes have generally begun with well de-

financed areas of production, with products sold primarily on the domestic market, with few processors or buyers, and with considerable ease of administration. These conditions are met by the British Columbia and all existing Ontario schemes, except those concerned with cheese, hogs and cream. The cheese and hog schemes deal with produce a large part of which is exported. The cream scheme involves many scattered producers, but with consumption entirely in Canada. The ease of administration, the requirements of contiguous producers, and few bottlenecks easily subject to control, suggest that producers in regions of scattered production feel they cannot acquire significant price and bargaining advantages through the existing marketing schemes. As illustration of this point certain marketing schemes have been abandoned. The Holland Marsh Growers' Marketing Board was abandoned after one season, 1937. Growers lost confidence in one centralized agency for the sale of lettuce. They were of diverse national origins, and slow to co-operate among themselves. Their major market was in nearby Toronto while their product had its peak demand at the time of its greatest perishability. For similar reasons a proposed South Essex Growers' Scheme considered in 1937 was not put into effect. The Erie-St. Clair Onion Growers' Marketing Board was withdrawn after the one season's experience in 1939, when farmers indicated their preference for the former marketing channels.

6. At this point it might be appropriate to discuss loopholes in the marketing schemes, and their bearing on the longer-run success of this form of price bargaining. With rare exceptions the schemes prescribe only the floor prices that must be paid for the product. The quantity to be purchased by the processor is not laid down, with the exception of canning tomatoes in the 1949 Ontario crop. If equilibrium price is defined as that which equalizes the quantity purchased by the buyers and the quantity that suppliers are willing to produce, then a low negotiated price becomes ineffective since buyers will bid up the price above this level. This often happened in the canning crop contracts during the war and early post-war years. On the other hand if the negotiated price is above the equilibrium price for the quantity produced, processors or buyers will limit their purchases to the quantities that they can handle with greatest profit. If the product is semi-perishable the balance must be disposed of on the fresh market for what it will bring. In the case of peaches, the fresh market has been considered the higher priced market. If peaches are not absorbed by the processors they

must be pushed on the fresh market or go to waste. In the case of asparagus the fresh market is considered the premium one, and asparagus is diverted to the processed market largely to ease the pressure on the price of fresh asparagus. For several years, the license fee collected from growers was used to subsidize the export of canned asparagus. While it is probable that mistaken price policies of those in charge of the schemes have forced some wastage of the fresh product, physical wastage may also occur from production in excess of the capacity of the processing plants. It is not always immediately clear how much wastage price policies have caused. Physical wastage of products covered by marketing schemes needs to be examined from both short-run and longer-run effects on producers' incomes and on inter-product competition. Higher producer incomes in the short-run may be obtained by some deliberate physical waste. Over the longer period other producers will expand their output to take advantage of this higher price. Meanwhile consumers will shift their purchases to other items which have not increased in price. Such producer gains, therefore, soon become dissipated.

7. If the negotiated prices have been raised above the competitive equilibrium level, the growers will find comparative advantages of crops with high fixed prices higher than other crops with lower fixed prices or completely free prices. Production of the high priced crop will increase, and the purchases by dealers will leave some of the crop unsold. In periods of sellers' markets the processors will try to pass on their higher costs of materials to consumers through higher retail prices. In periods of declining prices and buyers' markets, high fixed prices will reflect back to farmers in reduced purchases by the processors. Meanwhile consumers will shift their purchases to those items the prices of which have not risen or have fallen the most. For products which touch a high-income market or possess an inelastic demand, growers and processors have a short-run price-raising advantage which they may exploit. This has probably been the situation in the case of canned asparagus where surplus packs, which would depress Canadian prices, have been exported to the larger United States market. For products with greater price elasticities of demand, price increases quickly reflect to processors in lighter sales and to growers in lighter purchases by processors or dealers.

8. The schemes lack formal controls over each province's production. Price policy may encourage expanded production through

more acres, higher yields per acre or animal, or new producers not covered by the schemes. The situation report of the Dominion Department of Agriculture for 1948 indicated that more of the Canadian pack of canned vegetables is being grown in provinces not covered by marketing schemes. Quebec, the Maritime Provinces, Manitoba and Alberta had a larger portion of the pack of green and wax beans, canning corn, canning peas and tomatoes in 1948 than in 1943 to 1945. The increase in beans and tomatoes was particularly notable in Quebec, while Alberta showed more beans and canning corn. Ontario and British Columbia, which operated under marketing boards, were not retaining their proportion of the total Canadian pack of canning vegetables although this has been clouded by the general expansion in the canning of vegetables.

9. From the standpoint of the general public, another significant loophole has been the absence of interprovincial agreements between marketing boards concerning the prices of farm products. Where a product sold on a nationwide basis originates chiefly in one province the existing price is affected by the production of other areas. As an illustration of price-leadership arising from the price negotiation of a marketing board, the British Columbia Interior Vegetable Marketing Board is reported to have deferred the announcement of its prices for canning vegetables in 1949 until after the Ontario prices had been announced.⁵ This could permit British Columbia prices to be set to allow for interprovincial competition by its canned produce.

The interprovincial undercutting of prices may be eliminated or at least reduced in future by the collaboration of the major producing areas through interprovincial agreements under the federal Agricultural Products Marketing Act of 1949. On the other side of the picture the difficulties in the way of achieving this objective are likely to increase, especially in canned fruits. The rapid increase of British Columbia's pack of pears, plums, peaches, cherries and raspberries since 1935-39 means that products priced under the Natural Products Marketing Act (British Columbia) will soon compete severely with products priced under the Farm Products Marketing Act of Ontario (1946). The poultry groups have already given some consideration to having the marketing of poultry products brought under a national marketing agreement of some kind under the new federal legislation. To the extent that the major

⁵ Current Review of Agricultural Conditions in Canada, April, 1949, p. 14.

producing areas of the several provinces are able to effect joint arrangements price competition will be reduced.

10. All of the marketing acts mention as one of their objectives the improvement of marketing methods. This improvement is presumably additional to that already provided for by government agencies and the trading groups themselves. If improvements are introduced which influence quality, transportation or selling methods, they must arise from the study and appraisal of marketing alternatives. This implies that research in commodity marketing will be more lavishly endowed and more incisively analysed by the groups participating in schemes. Since the boards are staffed by grower representatives, this type of research into improved methods is likely to be conducted by part-time investigators following up hunches and the simpler forms of induction. The question may well be raised of the value of this research by self-interested commodity groups, in comparison with the results that might be secured by the established research agencies of government which would be free of commodity bias and special pleading. If, however, the boards make use of these existing research bodies, some very valuable results may be obtained.

11. Some of the Ontario annual contracts such as those for sugar beets and seed corn confine their content to the prices of clearly defined grades, terms of payment, and by-product allowances or adjustments. This may be compared to the short statement of principles contained in the collective bargaining agreements of well established labour unions and their employers. In other contracts such as the 1949 Ontario tomatoes for processing contract, the conditions of sale, grading, deliveries, payments, etc., are outlined in great detail. When such details must be arrived at by arbitration rather than peaceful negotiation there is clear indication that the working relationships of growers and processors are not characterized by mutual confidence and satisfaction. When the parties to the contract operate under such detailed regulations as exist in the tomato agreement, other differences almost inevitably will assert themselves and may be encouraged by resentment and hostility to the arbitration procedure. In other words, if goodwill does not already exist between growers and processors, it is much less likely to exist if detailed conditions are inserted in marketing contracts.

These considerations raise the question as to whether marketing boards have, generally, contributed to better producer-processor understanding. If each party to the negotiation must respect the

strength of the other, then their joint interest in productive efficiency, quality maintenance, and volume of sales may contribute to cost-reductions, pooling of knowledge, and the ascendancy of mutual interests over mutual conflicts. The financial success or difficulties of the processors is not a matter of indifference to the long-run interest of growers, while it is to the interest of processors to have their patrons near to their plants. In many cases the schemes, by enforcing collective as contrasted with individual bargaining, have contributed to goodwill which may ensure the continued existence of voluntary bargaining associations of producers should the schemes themselves be withdrawn.

12. Some commodity groups have, without doubt, asked themselves whether any significant results have been attained from the operation of marketing schemes. All Ontario schemes have the power to assess levies against farmers. Usually the levies are not large, and it is frequently pleaded that they are justified because of their modest size.⁶ Quite independently of the size of the levy it may be asked whether the course of development of the Ontario hog scheme (in effect since 1946), and the Ontario cream scheme of 1947 are likely to bring results which would justify their existence, and their financial support. In other words might not as significant marketing improvements have come from governmental agencies? To plead that the industry is complicated by export and interprovincial trade, by joint or by-product production on farms, and by competing demands of processors and consumers (e.g. milk, poultry and meat products), is to admit that the schemes are attempting to accomplish results that they should never have undertaken. The farmer may well ask whether well-considered economic research and food products regulation might not have given him just as good, if not better, results for each dollar taken from his gross income in taxes and levies.

13. The consensus of farm opinion seems presently to be in favour of marketing legislation.⁷ All provinces except Manitoba, Quebec and Prince Edward Island possess marketing legislation, while the Federal government has passed an enabling act allow-

⁶ The equalization fee of 38 cents a bushel on Ontario (field) beans, however, seems unduly large even to cover the price risk of the export market.

⁷ An exception which may reflect changing farmer opinion is the rejection of a proposed poultry products board of the Lower Mainland of British Columbia in a vote of July, 1949. In this case the bulk of sales was handled by a producer co-operative whose policy presumably was considered sufficiently attractive by farmers of the lower Fraser Valley.

ing interprovincial schemes.⁸ As has been mentioned, the provincial marketing boards are likely to find increased competition within Canada, particularly in canned fruits. An important question is whether marketing boards as presently constituted could provide for the reconsideration of contract prices, quantities and grade differentials if business conditions were to change suddenly and unexpectedly. The operation of the pools in British Columbia suggests that their act might be administered to deal with an emergency decline in consumers' purchasing power. Ontario's Act gives no indication of this flexibility and some commodity representatives insist that the success or failure of the processors is their own risk. Recognition of a greater common bond of interest is needed as well as provision for price-flexibility in case of emergency.

14. The question may be raised as to whether the stated objective of expanding domestic consumption and exports might not be brought about just as well by a programme of quality improvement with premiums and discounts for grades administered by the Departments of Agriculture as by any program that might be undertaken by marketing boards. Another important consideration is whether farmer co-operatives have been strengthened or weakened by price-bargaining under marketing schemes. Co-operative experience has shown that a fairly strict adherence to the Rochdale principles, and the confidence and criticisms arising from the individual members are essential to the long-run success of co-operatives.⁹ Unless co-operatives are constantly alert to member relationships and business developments, their support weakens. This is particularly a danger when difficulties in price and contract negotiations can be thrust on the governmental arbitrator. After all, governmental support cannot be presumed permanent. Co-operatives may have the strength to carry on without governmental price arbitration, as the Ontario tobacco groups have done since 1937, but they must be kept constantly alert. The question may be raised of how many farmer producer groups have the strength to stand on their own, and bargain with the processors and distributors if the government's support given to marketing boards was suddenly withdrawn. That would be the test of the strength of farmers' co-operative bargaining.

⁸ *Vide* article by A. H. Turner in this series. The agriculture of the new province of Newfoundland has been omitted as negligible.

⁹ This paper has assumed that "compulsory co-operation" is a misnomer in comparison with voluntary co-operation.

With the prospect of lower incomes for Canadian agriculture, policy decisions on marketing boards and schemes cannot be long delayed. One decision might be to reduce the scope of schemes to quality regulation which has been a traditional role of governments, with provision for price arbitration in case of serious breakdowns of negotiations between producer groups and produce buyers. The Alberta, Saskatchewan, New Brunswick and Nova Scotia Acts aim at approximately that objective, as does the revised Milk Control Act of Ontario (1948). Another decision might favor compulsory prorating of acreages or of marketings such as exists in the California Pro-Rate Act or the British Columbia Fruit Board. Both of these areas are geographically clearly defined, and therefore possess ease of administration. Still another policy might provide for governmental subsidies to support negotiated prices and volume of production or sales in case world prices should decline, as has been done in the United Kingdom since the war. Its feasibility would depend on the financial strength of the government, the degree of self-sufficiency of the nation in respect to food, and the magnitude of price declines. It might not be feasible in the Canadian provinces where food price declines would probably be a part of the general decline in all prices.

In conclusion, the experiences of the Canadian provinces with marketing boards have brought social innovations into marketing in the belief that marketing boards with farmer representatives, supported by the compulsory arbitration of governments, could attain increases in farm income through collective bargaining with distributors and processors. The gains in marketing efficiency have not been great, even in "orderly" marketings which have been the goal of British Columbia's boards, for it is not self-evident that governmentally supported boards are doing better than might be expected from voluntary co-operatives with good business leadership and storage facilities. Weaknesses and dangers exist in farmer attitudes toward the boards as a form of income security. Certain of the features, notably the pooling of knowledge of production and trade practices, and forward pricing have contributed to better understanding and improvements in quality, but these have been by-products of hard-headed bargainings over price. The provincial boards, especially in Ontario and British Columbia, must give greater consideration to the long-run consequences of their policies if they are to serve wisely the farmers and the general public.

DEVELOPMENT OF WHEAT MARKETING POLICY IN CANADA

G. E. BRITNELL AND V. C. FOWKE

University of Saskatchewan

PRODUCTION and marketing of wheat have been among the most important economic activities in the Dominion of Canada for the past half century. The Canadian wheat economy was created largely after 1900 in the Prairie Provinces, in the northern extension of the continental hard spring-wheat region. The settlement of this area provided tremendous population expansion and investment opportunities throughout the entire Dominion. Within a generation after 1900 the Canadian population doubled, reaching a total of 10.4 million people by 1931. Over the same period the population of the Prairie Provinces increased five-fold to a total of 2.4 million people. In 1900 less than one-twelfth of the Canadian population lived in the Prairie Provinces; by 1931 approximately one-quarter lived there.

Prairie lands "ready for the plough" were brought under cultivation by millions of acres. Ten million acres were in wheat by 1911, twenty-two million by 1921 and twenty-five million by 1931. Wheat crops which in the early years of the century were measurable in tens of millions of bushels increased to hundreds of millions of bushels. The average Canadian wheat crop (approximately 95 percent of which is grown in the Prairie Provinces) for the ten year period, 1929-38, was 309 million bushels. The average crop for the six war years, 1939 to 1945, was 439 million bushels. Four times Canada has harvested over half a billion bushels of wheat in a single year—in 1928, 1939, 1940 and 1942.

From a position of minor importance among Canadian exports in 1900, wheat and wheat flour advanced to first place by 1920. In the late 1920's wheat and flour yielded one-third of the dollar value of Canadian exports. Over the ten years 1929 to 1938 annual wheat exports averaged 200 million bushels. Throughout the second World War the average was 259 million bushels. Though Canadian farmers produce less than 10 percent of the world wheat supply, their exports—approximately two-thirds of their production—accounted for from 35 to 40 percent of the world trade in wheat in the late inter-war years.

These facts suggest the importance of wheat to the Canadian

economy. They suggest also that Canadian wheat marketing policy has always been essentially wheat export policy and, as such, has been the responsibility of the Dominion Government. It is important for the present analysis, therefore, to review the position of the Government in regard to the marketing of Canadian wheat.

Until very recent years Canadian governments at the federal level have held to the view that wheat should be marketed by the private trade and under the "open market" system, with government intervention limited to licensing and supervision. This view was maintained in spite of persistent advocacy of grain growers that it be abandoned in favor of state trading, and in spite of exigencies to be noted later which forced its temporary modification. Though it involves pre-judgment of the future to say so, it is argued in the present analysis that the action of the Dominion Government in creating a national monopoly of wheat marketing under the Canadian Wheat Board in 1943 marks a fundamental change in government attitude toward wheat marketing policy rather than merely another temporary modification dictated by abnormal expediency.

Under the open market system Canadian wheat was handled by specialized agencies, by elevator companies—whether "private" or co-operative—by commission agents, merchants and exporters. The central institution within this system, both functionally and symbolically, was the Winnipeg Grain Exchange. Until 1943 the futures market in the Winnipeg Grain Exchange was one of the great futures markets of the world. To the supporters of the open market system it stood as the symbol of all the virtues of free enterprise. To the grower it epitomized the hazards to which a freely moving price system may condemn a group of highly competitive producers in the marketing of their product.

The Dominion Government was first driven into active intervention in the Canadian wheat trade by the extremities of Allied food supply during the first World War. Faced by the gravest possible food crisis in 1916 the Allies established centralized buying of wheat in North American markets. By the early spring months of 1917 the Grain Export Company—the North American purchasing agency for the Allies—had secured a corner on Winnipeg May wheat. The fact that this corner developed in the course of *bona fide* efforts by the Allies to assure themselves of adequate supplies of wheat rather than for speculative purposes in no way modified

the trading panic which arose in the Winnipeg and Chicago markets when the shorts discovered their position and began to "run for cover." Futures trading was necessarily suspended temporarily and short positions were settled by agreement. In June, 1917, the Dominion Government established the Board of Grain Supervisors by Order in Council and endowed it with full power to fix the price of Canadian wheat and to determine its movement from the local elevator to the Allied purchasing agency. The urgency of the circumstances which called the Board into existence outlasted the war and the Board set the price for, and directed the movement of the crops of 1917 and 1918 as well as the balance of the 1916 crop. Prices set by the Board were \$2.40, basis No. 1 Northern Fort William,¹ for the balance of the 1916 crop, \$2.21 for the 1917 crop and \$2.24½ for the 1918 crop. Futures trading on the Winnipeg market was suspended on September 1, 1917, and remained suspended throughout the period of the Board's activities.

Persisting in the view that only the utmost abnormality in trading conditions could justify state intervention in the movement and pricing of Canadian wheat, the Dominion Government allowed the activities of the Board of Grain Supervisors to come to an end in 1919, with the intention, apparently, of permitting the private grain trade to function as it had before the war. Futures trading was re-established in Winnipeg for a few days in the latter part of July, 1919. It was quickly demonstrated, however, that conditions were far from normal by any pre-war test. Following consultation with representatives of the Canadian Council of Agriculture the Government established the first Canadian Wheat Board to handle the entire 1919 crop on a state monopoly basis.

The Wheat Board of 1919-1920 was modelled on Australian experience and differed in important respects from its Canadian predecessor, the Board of Grain Supervisors. Whereas the latter had established fixed prices and had directed the movement of Canadian wheat, the Wheat Board took title to all wheat marketed in Canada, paid the grower a fixed initial payment and issued participation certificates for whatever additional sums might be realized from the sale of the wheat. The wheat was then sold by the

¹ All wheat prices quoted in this article are on the basis of No. 1 Northern in store at Fort William-Port Arthur unless otherwise indicated. The Fort William-Port Arthur price includes certain fixed charges of approximately 20 cents a bushel for freight, elevator handling charges, inspection and grading fees, commissions, etc.

Board throughout the year at prices which were negotiated specifically for specific consignments. The total proceeds from sales less the initial payment were finally paid on a pro rata basis to the holders of participation certificates. The 1919 crop was marketed, in effect, on the basis of a state-operated compulsory pool. The initial payment was set at \$2.15 per bushel and additional payments brought the total proceeds to \$2.63 per bushel. In July, 1920, the Government, expressing its belief that the unusual circumstances which had justified the establishment of the Board no longer existed, stated that the Wheat Board would not function for the 1920 crop and that wheat marketing would revert to the "normal" methods of pre-war years.

Three years of complete control of Canadian wheat marketing by the Dominion Government had done nothing to alter the official viewpoint that grain should normally be marketed by means of the open market system. With the growers, however, it was a different matter. The possibility and comparative efficacy of a new system of marketing had, as far as they were concerned, been amply demonstrated. In the months which followed the restoration of open market trading in 1920 the price of wheat fell drastically. It was easy to argue that the Board, had it been continued, might have prevented or at least significantly tempered the decline. The growers accordingly were determined not to remain longer at the mercy of the open market system. From 1920 to 1923 they fought persistently to have the Wheat Board re-established. They abandoned the fight eventually only when repeated governmental rebuffs had finally convinced them that the fight was hopeless and when at the same time they came to believe that an alternative solution lay within their own power to put into effect. This alternative was that wheat might be marketed by cooperatively organized producers' pools without reliance on the futures market.

The wheat pool period is of considerable importance in the history of Canadian wheat marketing. Within the limits of the present analysis, however, this period can only be briefly commented on to indicate its significance for the development of Canadian wheat marketing policy. The provincial pools and the Central Selling Agency which were established in 1923 and 1924 were modelled on the non-stock, non-profit, voluntary contract type of commodity pools which had become prevalent in California in the war and early post-war years. The inspirational oratory of a colorful Cali-

fornia attorney, Aaron Sapiro, brought to western Canadian farmers the vision of a new economic gospel. The expansion and early successes of the Canadian wheat pools were little short of spectacular. Over the years from 1924 to 1931 the pools handled approximately one-half of the wheat marketed in western Canada.

In terms of wheat marketing policy the wheat pool period is of significance for two reasons in particular. In the first place, a good deal of evidence accumulated during the late nineteen-twenties to indicate that many wheat producers regarded the voluntary pools as but an imperfect substitute for a single compulsory pool sanctioned by legislation or, better still, operated by the Government as in 1919-1920. In the second place, the financial difficulties in which the pools became involved due to the collapse of prices after 1929 forced the Dominion government for a second time into a measure of market intervention far beyond anything regarded as normal in the field of Canadian grain marketing policy.

The financial difficulties of the wheat pools arose out of their system of financing in conjunction with a drastic decline in prices. For the 1929 crop the pools made an initial payment of \$1.00 per bushel, the funds being advanced by the banks on the security of warehouse receipts. In January, 1930, No. 1 Northern wheat at Fort William was priced at approximately \$1.40 per bushel. By a persistent decline throughout the ensuing months wheat was worth just over 50 cents per bushel by the end of the year. With the value of the bank-held collateral impaired, the pools in February, 1930, secured the guarantees of their respective provincial governments, and in November the guarantee of the Federal Government. The Federal guarantee was conditional upon the appointment of a government nominee as general manager of the Central Selling Agency. With the appointment of John I. McFarland to this position the Central Selling Agency became in effect a public rather than a producer-controlled marketing agency. Its primary purpose was to save the Canadian grain trade from total collapse and in this way to support the Canadian banking, business and agricultural community.

Mr. McFarland's activities in the wheat trade from 1930 to 1935 were financed by funds secured under Federal guarantee and came to be known as "stabilization" operations. These operations at first involved the withholding of the pool carry-over from the market. In July, 1931, Mr. McFarland began under Order-in-

Council instructions to purchase wheat futures for price stabilization purposes. On his appointment as general manager of the Central Selling Agency he had taken over some 77 million bushels of pool wheat. By May, 1935, he held a maximum of 230 million bushels of wheat and wheat futures. The maximum bank indebtedness of the Agency under government guarantee was \$80 million.

In 1935 the Dominion Government established a national Wheat Board for the second time. This action did not, however, represent abandonment by the Government of its traditional view that Canadian wheat should normally be marketed by private agencies. It is true that one factor in the decision of the Government to re-establish the Board in 1935 was the persistent pressure of wheat producers to have it re-established. Over the period from 1920 to 1935 there were not more than four consecutive years without the open advocacy by producers of some form of monopolized marketing of the Canadian wheat crop. But when the decision to re-create the Board was finally taken it was only partially related to this fact and was much more closely related to political considerations and the necessity for regularization of stabilization activities in view of an impending federal election. The original government measure providing for a new wheat board (Bill 98, first read on June 10, 1935) contemplated a monopoly board—a monopoly *grain* board, in fact, rather than a wheat board. The measure as it was finally passed, however, after consideration by a special committee of the House, established the Board merely as an optional marketing channel which would free the producers from dependence upon the open market system without in any way interfering with that system. Mr. McFarland was appointed Chief Commissioner of the Board.

The development of the Dominion Government's wheat marketing policy since 1935 can now be traced in the record and experience of the Canadian Wheat Board over 15 years of extremely diverse production and marketing conditions.²

Under the Canadian Wheat Board Act the Board, which consisted of three members appointed by the Governor in Council, was

² See *Annual Reports of the Canadian Wheat Board, Crop Years 1935-36 to 1947-48* (Winnipeg, 1936-49). See also the admirable monograph prepared by Dr. T. W. Grindley, former Secretary and, since 1948, one of the Commissioners of the Wheat Board and his associates, *The Canadian Wheat Board, 1935-48* (Ottawa, King's Printer, 1947), pp. 87, and *Summary of Operations of the Canadian Wheat Board, 1935-36 to 1947-48* (Winnipeg, the Canadian Wheat Pools, 1949), pp. 12.

given power to accept deliveries of wheat from producers at a minimum guaranteed price (subject to the approval of the Governor in Council), and to make an equitable distribution to producers of any surplus resulting from the operations of the Board during any crop year, or, in the event of loss, to transfer such deficit to the Dominion Government.

In determining the guaranteed, minimum price the Board had to weigh a variety of economic, social and political factors. On the basis of the financial outcome it seems probable the 1935 price resulted from a fairly shrewd appraisal of (a) fair market value and (b) what the farmer with an average crop needed to "get by." On September 6, 1935, the Board announced a minimum price of 87½ cents per bushel, a figure slightly above the current open market price. The open market price immediately rose to 89 cents and stayed above the Board minimum for six or seven weeks—providing the producer with an optional marketing system. Many producers did, in fact, deliver to the Board during this period and when the market price finally fell below the Board's and remained there for almost eight months self-interest meant that all deliveries went to the Board. A market recovery in June restored the optional marketing plan. The Board finally received 150.7 million bushels—or about 70 percent—of total producer deliveries of 216.3 million bushels in the 1935-36 crop-year.

Replacement of the Conservative government by a Liberal administration following the Dominion General Election of October 1935, involved changes in the personnel and the selling policy of the Board. A new Board with J. R. Murray as Chief Commissioner replaced the McFarland Board at the beginning of December, 1935, and the Minister of Trade and Commerce announced a more vigorous sales policy designed to reduce "the concentration of surplus stocks of wheat in Canada."¹ Crop failures in Argentina and the United States in 1935 and the North American drought in the summer of 1936, enabled Canada to secure a large part of the relatively small world trade in wheat. As a result by the end of the 1935-36 crop year the Board had on hand only two million bushels of the 1935 crop and had reduced the "stabilization" holdings to 82.7 million bushels as compared with the 205.7 million bushels taken over at the beginning of December, 1935. The

¹ *Report of the Canadian Wheat Board, Crop Year 1935-36*, p. 2.

Board's operations showed a final net loss of \$11.9 millions on the 1935 crop after the last sales in November, 1936.

For both the 1936 and 1937 wheat crops the Board fixed a price of 87½ cents, basis No. 1 Northern, Fort William or Vancouver, each year, but the Government in approving this price added a qualification that it would only become effective if the open market price should fall below 90 cents a bushel. With short crops in both Canada and the United States in 1936 followed by a disastrous drought in Canada in 1937 demand improved and prices were maintained well above the 90 cent level so that the Wheat Board accepted no wheat from producers in either crop year. Thus, for two years, the wheat policy of the Government denied farmers the opportunity of pooling their wheat through the Board under market conditions which gave "assurance that initial payments on the Board's minimum basis could be supplemented by substantial distributions on participation certificates."⁴ The Board completed liquidation of the remaining stocks of "stabilization" wheat at a net profit of almost \$9 millions so that the net loss on the Board's operations to July 31, 1938, were reduced to approximately \$2.9 millions.⁵

With the opening of the crop year, 1938-39, the Government's retreat from intervention in wheat marketing came to an end. Both world and Canadian carry-overs were back to normal or even lower but in 1938 world wheat production reached an all-time peak with good yields harvested from a record world wheat acreage. World demand continued at a very low level and prices had fallen sharply, when, after a Royal Grain Inquiry Commission had recommended the continuation of the Canadian Wheat Board,⁶ the Government announced approval on August 4, 1938, of a minimum Board price of 80 cents a bushel. Since market prices remained consistently below this figure all deliveries (amounting to 292.4 million bushels) went to the Board. The eventual loss to the Dominion Treasury on the 1938-39 crop, following final sale of the 86.5 million bushel carry-over in the crop year 1939-40 and a final accounting in April, 1942, was placed at \$61.5 millions.⁷

⁷ *Report of the Canadian Wheat Board, Crop Year 1941-42*, p. 23.

Faced with a heavy loss on the 1938 crop the Government had, at the 1939 session of Parliament, secured two important amendments to the Wheat Board Act. (1) the fixed initial price for the 1939 crop was established at 70 cents a bushel thus relieving the Board of this responsibility; (2) deliveries from any one producer were limited to 5,000 bushels in any one crop year.⁸ Further Dominion legislation facilitated organization of agencies to market excess wheat on a co-operative basis.⁹

When a new crop year opened August 1, 1939, the necessity of continued governmental support of wheat prices was indicated by a carry-over of 100 million bushels and a new crop which promised to exceed 500 millions. The outbreak of war a month later brought an improved export demand and open market prices during the period of heavy movement from the farms approximated the Board's initial payment with the bulk of such deliveries going to the Board. With a further improvement in export sales beginning in December, 1939, the open market price began to rise again and, with buying for Canada's largest customer concentrated in the hands of the Cereals Import Committee of the United Kingdom, the open market price levelled out at about 90 cents—or about 20 cents above the Board minimum—from January until the middle of May, 1940.

Encouraged by this situation prairie farmers, having survived ten years of drought and depression, seeded two million extra acres of wheat in the spring of 1940 in the hope of recouping their fortunes in a wartime wheat boom like that of 1914-18. The 1940 wheat crop was scarcely in the ground before export markets for Canadian wheat felt the full impact of the German *Blitzkrieg*, Winnipeg futures dropped 30 cents in one week and at the request of the Board the Grain Exchange set minimum prices below which no trading would be allowed. By midsummer extensions of German conquest and the exigencies of the British blockade had left Portugal the sole remaining customer for Canadian wheat on the continent of Europe. Apart from a few small, scattered and uncertain markets, the Board was left to negotiate block sales to the United Kingdom such as the 50 and 100 million bushel sales in May and August respectively.

⁸ *Statutes of Canada*, 3 Geo. VI, c. 39.

⁹ *Statutes of Canada*, 3 Geo. VI, c. 34. See also G. E. Britnell, "Dominion Legislation Affecting Western Agriculture, 1939" (*Canadian Journal of Economics and Political Science*, Vol. VI, May, 1940, pp. 275-282).

The Board's statutory initial price of 70 cents a bushel continued in effect for the 1940-41 crop year but the storage problem presented by a new crop of 540 million bushels—a near record crop for the second year in succession—to be added to a 300 million bushel carry-over necessitated further regulation of deliveries. To divide available elevator space as fairly as possible, quota permit books based on sworn seeded acreage were issued to producers. A schedule

^b Exclusive of consumption of 5.7 million bushels imported from the United States.

^c Preliminary estimates.

of storage payments on farm-stored wheat was introduced. In view of the probable absence of any effective optional marketing arrangement the 5,000 bushel limitation on deliveries was removed. Because of the abnormal export situation a processing levy of 15 cents a bushel on all wheat utilized for human consumption in Canada was imposed.¹⁰

Bulk sales, covering 220 million bushels, were the main method of wheat disposal for export. Little use was made of the futures

¹⁰ See *Statutes of Canada*, 4 Geo. VI, c. 25. In the crop-year 1940-41, farm storage payments amounted to \$6.1 millions; net revenue from the processing levy (discontinued, July 31, 1941) was \$5.9 millions.

market. With the co-operation of producers and elevator companies it was possible to take delivery of all marketable wheat, but at the close of the crop year the Board held unsold stocks of 254 million bushels from the 1940 crop along with 115 millions from the 1939 crop¹¹ the latter eventually being disposed of at a loss of \$8.2 millions to the Treasury.

From the beginning of the 1940-41 crop year, at least, Canadian wheat statistics had pointed, with harsh urgency, to the necessity of some curtailment of wheat production. (See Table I which shows the annual statistical position of Canadian wheat from the inception of the Wheat Board in 1935.) Faced with a prospective 500 million bushel carry-over in Canada the Government therefore announced, in March, 1941, that wheat deliveries to the Board and to the open market in the crop year 1941-42 would be restricted to 230 million bushels—the amount which it was estimated could be used to meet demand at home and abroad in the year—and that the accumulated stocks as at July 31, 1941, would be carried as a wartime reserve. In the administration of the new policy by the Board the “authorized acreage” for delivery purposes under the quota system was established for each producer on the basis of 65 percent of his declared 1940 wheat acreage. The Board’s statutory initial price of 70 cents was to continue in effect with storage payments to producers on the same basis as 1940-41 “but only on the undelivered portion of the 230 million bushels.” Compensation in the form of acreage bonuses for land taken out of wheat and diverted to summerfallow (\$4 an acre) or to coarse grains or grass (\$2 an acre) was offered. Diversion of wheat acreage to the production of oats and barley in particular was defended in terms of encouraging livestock production, the doubling of bacon and cheese exports to Britain, and the improved domestic market for livestock, dairy and poultry products.¹²

The Government’s program resulted in a reduction of approximately seven million acres or 24 percent in the area sown in wheat. With a light crop total marketings, after all quotas had been lifted, at 228 million bushels in 1941-42 were exactly one-half those of the

¹¹ See *Report of the Canadian Wheat Board, Crop Year 1940-41*, pp. 13-14.

See also three government pamphlets (1) *Canada's Wheat Problem*; (2) *A Plan to Reduce Wheat Acreage and Make More Money Available for Necessary War Supplies*; (3) *Less Wheat in 1941 Will Help Win the War* (Ottawa, King's Printer, 1941).

previous year. With a smaller crop and the government's policy of treating former surpluses as wartime reserves, the open market price remained somewhat above the Board price throughout the year so that the Board received only 44 percent of farm deliveries in 1941-42 as against almost 90 percent of the large 1940 crop. Two sales, each of 120 million bushels were made to the United Kingdom (one in November, 1941, the other in May, 1942), and the total Canadian wheat carry-over was reduced by nearly 60 million bushels during the year. It should, however, be noted that since the greater part of the wheat economy was ill adapted to the government's diversification program the economic and social costs, particularly to Saskatchewan, were not inconsiderable.¹²

Government wheat policy for the crop year 1942-43 reflected no change from the previous year beyond the fact that the Board's fixed initial price was increased to 90 cents (after being held at 70 cents for the previous three years) with marketings limited to 280 million bushels for Western Canada compared with 230 millions for all Canada in the previous crop year. Wheat acreage reduction payments were continued, the reduction in wheat acreage was maintained, and the expansion of feed grain acreages was accelerated with the establishment in March, 1942, of minimum prices for oats and barley. In line with its over-all price control policy, the government held the price of wheat entering into domestic consumption to 77½ cents per bushel by payment through the Board of a drawback to millers.

With a very large wheat crop and record productions of oats and barley yielding large marketable surpluses of these grains, delivery quotas for wheat were increased very slowly to a maximum of 15 bushels per "authorized acre" and large stocks of wheat accumulated on farms in the main wheat areas, increasing the pressure to transform the wheat economy into a coarse grain and livestock economy. Thus, in the three years from 1940 to 1942 Canadian wheat acreage was reduced nearly 40 percent—from 28.7 to 16.9 million acres. Early in 1943 improved demand became a noticeable factor so that by March the open market price had moved above the Board's initial price and 38 percent of the total

¹² See G. E. Britnell, "The War and Canadian Wheat," (*Canadian Journal of Economics and Political Science*, Vol. 7, August, 1941, pp. 397-415), L. A. Skeoch, "Changes in Canadian Wheat Policy" (*Ibid.*, Vol. 9, Nov., 1943, pp. 566-569), V. C. Fowke, "Effects of the War on the Prairie Economy" (*Ibid.*, Vol. 11, August, 1945, pp. 373-387).

"authorized deliveries" were marketed through the Exchange and 62 percent through the Board.

On September 27, 1943, the Dominion Government announced a complete change in wheat policy which may be summarized under five heads:

- (1) The discontinuance of wheat trading on the Winnipeg Grain Exchange;
- (2) The raising of the fixed initial price to producers from 90¢ per bushel to \$1.25 per bushel for No. 1 Northern wheat;
- (3) The purchase by the Board, on behalf of the Dominion Government, of all stocks of unsold wheat in commercial positions in Canada on September 27th, 1943;
- (4) The closing out of the 1940-41, 1941-42 and 1942-43 Wheat Board Crop Accounts on the basis of closing market prices on September 27th, 1943;
- (5) The use of Government-owned wheat (Items 3 and 4 above) to meet requirements under Mutual Aid and to provide wheat for subsidized domestic purchasers.¹⁴

The new policy gave the Wheat Board a monopoly of Canadian wheat marketing. It made for efficient allocation of supplies to domestic and to export markets and a more effective utilization of storage and transportation facilities; it helped to restore the income of the western wheat producer which had been depressed by low prices and low delivery quotas while at the same time the problems of the Government's price control policy were eased by the large stocks which it now controlled.¹⁵ Government purchase of the unsold stocks from the 1940, 1941, and 1942 crops at the closing price on September 27, 1943 (which was \$1.23½ basis No. 1 Northern in store Fort William) made it possible to arrange final payments to producers on all these crops within the next twelve months (see Table II).

The change in wheat marketing policy which was made in 1943 placed the Dominion Government in a strategic position for the formulation of policy for the post-war period. The Government made it clear that the first consideration would be to supply Canadian wheat in maximum quantities to meet the desperate food requirements of European countries. For the longer run the Government has consistently pursued the goal of greater market stability

¹⁴ See *Report of the Canadian Wheat Board, Crop Year 1943-44*, p. 8.

¹⁵ See Skeoch, *op. cit.*

for the wheat economy. Two decisive steps were taken in the implementation of this policy in 1946: the negotiation of the United Kingdom Wheat Agreement, and the creation of a five-year national pool for Canadian wheat.

The United Kingdom Wheat Agreement as announced July 24, 1946, provided that the Canadian Government would supply 600

^b Changed from \$0.90 to \$1.25 on 27 September, 1943.

^c Participating payment was \$0.18677 for top four grades and sub-grades; for No. 5 and lower, the payment was \$0.20677 per bushel.

million bushels of wheat to the United Kingdom over the four crop years, 1946-47 to 1949-50, 160 million bushels for each of the first two and 140 million bushels for each of the last two years. For the first two years the price was to be \$1.55 per bushel basis No. 1 Northern Fort William, Vancouver or Churchill; for the third and fourth years the price was to be negotiated above minima of \$1.25 and \$1.00 for the respective years. Exports outside the

contract would move at "world" prices with special regulations concerning the price to Canadian millers for domestic purposes.

As the domestic complement of the United Kingdom Agreement the Government announced the creation of a five-year pool for Canadian wheat. The arrangement here was that the Wheat Board would continue as the sole purchaser of Canadian wheat and that the crop years 1945-46 to 1949-50 would constitute a single pool, the producers to receive an initial payment on delivery with participation certificates to represent their further equity. The initial payment for 1946 was set at \$1.35 and a 10 cent interim payment was declared on deliveries for the 1945-46 crop year to add to the \$1.25 which had already been paid on such deliveries. Amendments to the Wheat Board Act in March, 1947, extended the monopoly control of the Board to July 31, 1940, the expiry date of the United Kingdom Agreement and of the five-year pool.

With Canada entering upon the final year of the Agreement and of the national pool, only a progress report of their results can be given. Wheat moved to Britain according to contract for the crop years 1946-47 and 1947-48 at \$1.55 per bushel. For the first of these years the Board averaged \$2.43 per bushel for wheat exported outside the contract (Class II wheat); for the second year the average was \$2.88. On the basis of negotiation the price of wheat for Britain for the years 1948-49 and 1949-50 was set at \$2.00 per bushel. Meanwhile the price of wheat for domestic milling purposes varied from \$1.25 to \$1.55 to \$2.00 per bushel. It can be readily seen that the Board accumulated substantial funds over and above the \$1.35 initial payment. With these funds the Board has made interim payments on participation certificates, 20 cents per bushel on April 1, 1948, and an additional 20 cents on April 1, 1949. With each interim payment made on past deliveries the initial payment was correspondingly raised for future deliveries. Canadian farmers have thus received \$1.75 per bushel, basis No. 1 Northern Fort William, for their deliveries since August 1, 1945, and are receiving this amount as the initial payment for deliveries from the 1949 crop.

Table II provides a concise summary of the Wheat Board's payments on a bushel basis from its inception in 1935.

The Canadian producer and the Canadian Government are not alone in seeking to introduce a greater measure of stability into

the world wheat trade. In March, 1949, the representatives of some forty countries signed the International Wheat Agreement in Washington. This agreement, since ratified by the requisite countries to put it into effect, marks the culmination of nearly two decades of effort. The agreement covers the four-year period from August 1, 1949, to July 31, 1953, and carries the commitment of five exporting countries to supply and of 36 importing countries to accept quantities of wheat totaling approximately 450 million bushels of wheat annually. The exporting countries and their respective annual supply commitments are: Canada, 203 million bushels; United States, 168 million; Australia, 80 million; France, 3.3 million; and Uruguay, 1.8 million. Chief among the importers is the United Kingdom, committed to take 117 million bushels annually. Significantly absent from the list of signatory exporters are Argentina and Russia. The agreed quantities are to move at prices limited to specific maximum and minimum figures. The maximum is \$1.80 per bushel for each of the four years. The minimum is \$1.50 per bushel for the first year and 10 cents less for each succeeding year, or \$1.20 for the fourth year.

It is too early to forecast the outcome of the International Wheat Agreement with any degree of certainty. In fact, the future course of the Agreement is hardly relevant to Dominion wheat marketing policy at the present time. The significant point in current circumstances is that governments of wheat exporting and importing countries no longer regard state trading in wheat as a temporary expedient to be abandoned at the first signs of the return to post-war normality. This is in sharp contrast to the general policy pursued in the years following the first World War. Though particular national wheat boards and international agreements may succeed or fail we are not likely soon to see a restoration of the open market system in the international wheat trade. So far as Canada is concerned the Government has already extended monopoly control of wheat to 1951 and at no time has the Canadian Government intimated that the open market system would be restored then or at any later date.

THE PROPOSAL TO MARKET COARSE GRAINS THROUGH THE CANADIAN WHEAT BOARD

G. L. BURTON*

Macdonald College, McGill University

THE Government of Canada has recently announced its intention, beginning with the new crop year starting August 1, 1949, of making the Canadian Wheat Board the sole marketing agency for oats and barley produced and sold in the Prairie Provinces of Manitoba, Saskatchewan and Alberta. Since September of 1943 the Wheat Board has been the sole marketing agency for wheat in this designated area. The initial price paid to the producer has been fixed by the Governor-in-Council, that is, the Cabinet, while surpluses realized on the disposal of this wheat have, after the deduction of expenses, been pro-rated back to those farmers delivering wheat. The cash and futures markets are closed.

Although the ownership of the elevator system remains in the hands of private firms, or co-operatives, the Canadian Wheat Board Act of 1935 confers upon the Board the power to regulate the deliveries of wheat, oats, barley, rye and flaxseed to these elevators. The Board issues a delivery permit book to each farmer and may, at its discretion, establish delivery quotas. Also, the Board may require that, unless delivered under a permit book, grain may not be loaded onto a railway car without the permission of the Board. The Act gives the Board a monopoly over all inter-provincial and export trade in wheat and by an amendment of March 19, 1948, extends this monopoly to oats and barley.¹ At the time of writing, trading on the Winnipeg Grain Exchange in cash and futures contracts for all grains, other than wheat, is still taking place.² It is assumed that with the Board undertaking the marketing of oats and barley produced in the designated area in inter-provincial and export trade the cash and futures market will not be able to operate once existing contracts are cleared.

Although Bill 135 was passed more than a year ago the Government refused to proclaim this amendment until the governments

* The writer wishes to acknowledge careful criticism of an earlier draft of this paper, by W. M. Drummond, E. C. Hope, W. J. Parker, M. W. Sharp and A. M. Shaw.

¹ Bill 135, Fourth Session, Twentieth Parliament, 11-12 George VI, 1947-48.

² In the case of wheat, trading has never been legally prohibited but has simply ceased to occur because there isn't enough wheat outside the control of the Wheat Board to make it possible.

of the three Prairie Provinces had passed complementary legislation.³ This complementary legislation, making the Wheat Board the exclusive marketing agency, was desired inasmuch as the Government feared that without it the powers given by the amendment might not be sufficient to ensure an effective monopoly in oats and barley marketing. The governments of the Prairie Provinces passed the requested complementary legislation but not before the Premier of Manitoba had asked some very searching questions as to how these grains were to be priced. These questions were never satisfactorily answered. Mr. Garson has since joined the Dominion Cabinet and, if such pricing criteria have already been devised, they have not been made public.

The proposal to place the marketing of these grains under the exclusive jurisdiction of a government board, with the consequent emasculation of the cash and futures market, has had the unqualified support of the Canadian Federation of Agriculture. Farmers in Western Canada have exhibited chronic dissatisfaction with the Grain Exchange and, at their request, this institution has been periodically investigated. Professor Fowke, after recording the appointment by the Dominion Government of seven Royal Commissions to investigate the grain trade between 1899 and 1939 has this to say:

More than any other thing the wheat growers criticized the Winnipeg Grain Exchange with its organized speculation on the futures market. . . . The prairie farmers have attacked this organization for the past forty years as the symbol of their exposed and residual position within a price system in which other groups have entrenched themselves behind tariffs, price controls, and trade association agreements. For forty years Canadian agricultural commissions have defended the Grain Exchange, again as a symbol, but for them a symbol of the beneficence of the price system.⁴

Farmers in the specialized grain growing areas of the Prairie Provinces are subject to a high degree of both output and price

³ In a letter to the Hon. Stuart Garson, Premier of Manitoba, Mr. Howe, Minister of Trade and Commerce in the Dominion Government wrote: "Complementary legislation in Alberta, Saskatchewan and Manitoba is required to make Wheat Board prices effective. Provincial legislation in Ontario is desirable, but perhaps not necessary, as the competitor situation as between Western coarse grains and Eastern coarse grains will tend to hold prices in line." See *Manitoba's Position on Oats and Barley Marketing*, a copy of the correspondence between Hon. Stuart Garson and Rt. Hon. C. D. Howe, Minister of Trade and Commerce, King's Printer for Manitoba, Winnipeg, 1948, p. 11.

⁴ V. C. Fowke, *Royal Commissions and Canadian Agricultural Policy*, *The Canadian Journal of Economics and Political Science*, Vol. 14, No. 2, (1948), p. 173.

uncertainty. Yields vary widely from year to year. When low yields coincide with periods of low prices, as was the case in the mid-thirties, the farmers' position is desperate. During a period of depression the terms of exchange turn against agriculture; farmers seek, therefore, to escape from the open market and to secure some type of administered price which will be less subject to cyclical fluctuations. Their experiences with a government wheat marketing monopoly have been rather satisfactory, partly because these boards have been in operation either during, or immediately after, the last two wars when the market prices of bread grains were extremely high. The prairie farmer is inclined to ask why, if he is to have a government wheat marketing monopoly, he should not have the same board market his oats and barley.⁵

The structure of the market for oats and barley is essentially different from that for wheat. Canada normally exports about two thirds of her wheat crop. The price obtainable in the export market offers a convenient guide to the government in fixing a price to the domestic consumer. At the present time the price of wheat for food and feed in Canada is the same as the price specified in the export contract with the United Kingdom, with, of course, allowance being made for differences in grade. Since roughly 95 percent of the total output of oats and 85 percent of that of barley is used within the country, and since there is an even less clearly discernible world market price for these grains, it seems unlikely that the export price will provide an adequate guide even if it were considered desirable to establish the domestic price at this level. Certainly the price of feed grains in the United States must be considered in fixing the price to the feeder. American corn, subject to a duty of eight cents per bushel, may be imported if its price is sufficiently lower than the domestic prices of coarse grains. Since corn prices are supported under the parity program in the United States the use of laid down corn prices as a guide would raise the price of feed grains to the Eastern feeder by the amount of the effective price support plus the tariff.

Coarse grains compete with wheat for available acreage in the

⁵ The first Canadian Wheat Board of 1919 was a monopoly; it purchased all wheat offered for sale in commercial channels. The second Wheat Board of 1935 bought at a pre-determined initial price but the market for cash and wheat futures was left open until September of 1943. During this period the farmer had the option of selling either to the Board or on the open market depending upon the relative prices offered.

Prairie Provinces. Of the 60 million acres cultivated in these three provinces roughly 26 million is seeded to wheat, 14 million to coarse grains and the remaining 20 million are summerfallowed. The coarse grain acreage is concentrated in the black soil zone to the north where it claims a third of the cultivated acreage with a like proportion being devoted to both wheat and summerfallow. This is the mixed farming area where hogs, beef and dairy cattle enterprises are found on many farms, although wheat is still the primary cash crop. On the short grass plains to the south coarse grains claim some 10 percent of the cultivated acreage with wheat occupying nearly a half and summerfallow the remaining 40 percent.⁶

A high proportion of these coarse grains are fed on the farms where grown. Farmers' marketings average about 38 percent of production for oats and 46 percent for barley. Under the Freight Assistance Program roughly half the oats and barley marketed in Western Canada have been shipped to Eastern Canada and British Columbia. Although statistics for pre-war shipments are not available they are known to have been much smaller.

The operator of a typical one-hundred acre farm in Ontario or Quebec finds that he can increase his net farm income by intensifying production. Much of the land in Central Canada as well as in the Maritime provinces of New Brunswick and Nova Scotia is better suited for the production of grass than grain. Since 1941 the Dominion Government in an effort to expand the output of live-stock, dairy and poultry products has paid the freight on some 753 million bushels of grain moving from the Prairies into Eastern Canada and British Columbia.⁷ Between 1943 and 1947 farmers in Eastern Canada imported from the west as much feed grain as they, themselves, produced. Prior to the removal of price ceilings on grains and livestock in October of 1947 the feeder was also granted a "drawback" on purchased grain used for feed.⁸ These subsidies

⁶ Estimates are derived from unpublished data compiled by the Canadian Wheat Board from producers' delivery permits.

⁷ Data from Feeds Administration, Dominion Department of Agriculture, Ottawa.

⁸ The practice of allowing a "drawback" to the feeder of wheat is inequitable in its application as between feeders in Western Canada buying grain and those producing all or part of their own feed grains. A similar criticism may be made of the practice of distributing "equalization payments" on coarse grains. During the war and immediate post war years anyone exporting coarse grains to the United States was required to secure a permit and to pay to the Board the approximate amount by which the price in the United States exceeded that in Canada. This device per-

on feed grain, shared by the farmer and consumer, have served to expand the domestic market for western feed grain. The Canadian Federation of Agriculture urges their continuance as a permanent part of our agricultural policy.

How Will the Government Price Feed Grains?

This is certainly the fundamental issue which must be met once the open market is closed and the buying and selling prices of oats and barley are fixed by the Cabinet.⁹ The first reaction of Mr. Howe, Minister of Trade and Commerce, whose department is responsible for the administration of the grain trade, was "to look to the Canadian Federation of Agriculture to recommend prices for oats and barley satisfactory both to producers and feeders."¹⁰ Since the Federation represents both the grain growers in the west and the feeders in the east, one may assume that the reception accorded to this suggestion was something less than enthusiastic.

Despite the obvious advantages of this inter-regional trade in feed grains it complicates the problem of administered pricing. Prairie farmers would like to sell their surplus oats and barley at prices which would, over a period of years, maximize their receipts from such sales; eastern farmers, on the other hand, would like to pay as low a price as is consistent with an adequate and assured supply of feed grains. There is, then, a rather sharp divergence of interest between the two groups of producers as to the price which should be fixed for oats and barley.

Evidence of this divergence of interest between the producer and feeder of coarse grains is to be found in a resolution passed by the Western Agricultural Conference. This Conference, which is made up of delegates representing organized agriculture in the four

mitted exports while protecting the domestic price ceiling. Receipts from "equalization fees" were pro-rated back to all farmers who had delivered grain.

The real cost to the farmer feeding grain which he had grown was the selling price of that grain. This was greater than the purchase price to the non-grain-growing feeder, in the case of wheat, by the amount of the "drawback" plus the participation payment, in the case of coarse grains by the "equalization payments." Although all of these payments, except the participation payment on wheat, have now been discontinued, this situation could recur if, once the marketing of coarse grains are brought under the Wheat Board, the price to the producer is fixed at a higher level than the price to the feeder.

⁹ Subsection (c), section 29A of Bill 135, An Act to Amend the Canadian Wheat Board Act, 1935, provides that the initial prices paid to the producers of oats and barley are to be fixed by the Governor-in-Council, i.e., the Cabinet. Presumably the Board is to offer coarse grains at prices approved by the Cabinet.

¹⁰ *Manitoba's Position on Oats and Barley Marketing*, p. 8.

western provinces, met in Saskatoon on January 20 of this year. The resolution dealing with coarse grains was as follows:

"that a joint effort be made to enable the Canadian Wheat Board to be the sole marketing agency for coarse grains and that any legislation giving the Canadian Wheat Board the same exclusive powers over the marketing of other grains as it now exercises over wheat, should be based on the principle that the Canadian Wheat Board should be an agency operating in the interests of grain producers, with a duty at all times to sell grain for the best available price whether in export or domestic markets, and should not be used as an instrument of government policy to limit domestic prices."¹¹

This resolution immediately raises the question as to what the Conference meant when they asked that the "Board should be an agency operating in the interests of grain producers, with a duty at all times to sell grain *at the best available price* whether in export or domestic markets." The Wheat Board Act states that the Board "shall sell and dispose of grain . . . at such prices as it considers *reasonable* with the object of promoting the sale of grain produced in Canada in world markets."¹²

One might conclude that the Conference would have the Cabinet, or the Board, so fix the selling prices of coarse grains as to maximize the Board's receipts from such sales over any given period of time.¹³ If this were done the government would, in effect, be establishing a monopoly on behalf of the western grain grower.

The Ontario Federation of Agriculture apparently does not believe that the Board, although the agent of the producer, need price feed grains in this way. At their annual meeting they passed the following resolution:

Coarse Grains Marketing

Whereas 72 percent of farm income in Ontario is received for livestock products;

And whereas reasonable stability in feeding costs is necessary to build and maintain this industry at high levels;

And whereas speculative fluctuations in the prices of coarse grains do not promote this necessary stability;

¹¹ As reported in the Manitoba Co-operator of January 27, 1949.

¹² The Canadian Wheat Board Act 1935, subsection 1 of section 5 of Part I.

¹³ The period of time considered may prove very important. Prices which would maximize receipts over a day or a week might yield less than maximum receipts over a longer period because of their effect upon feeders' production decisions. If the objective is to adjust price at that level at which the price elasticity of demand is unity, the price fixing agency might well find the elasticity of demand to be greater over a longer period of time and hence warrant a lower price.

Therefore be it resolved that the Ontario Federation of Agriculture in annual meeting assembled ask the Canadian Federation of Agriculture to press whatever negotiations are necessary to have coarse grains marketed in the prairie provinces come under the control of the Wheat Board, and in pressing this request, we agree that:

1. The Board should be the agent of the producers of coarse grains.
2. The selling policy of the board should be based on the free supply and demand situation for coarse grains both in Canada and in export markets but the Board should take steps to see that adequate feed reserves are maintained in Canada to safeguard the livestock industry which, in the long run, is the most important market for coarse grains produced in Canada.
3. The Board should have an advisory committee recommended by the Canadian Federation of Agriculture which committee should be representative of the growers and the feeders of coarse grains.

It is apparent that farm leaders in both eastern and western Canada believe that the government can establish prices which are "fair to producers and consumers alike." Both groups are anxious to escape from short run fluctuations in price which they regard as unnecessary. Any reduction which can be achieved in price variation and/or any increase in price certainty through the announcement of minimum or maximum prices in advance may well lessen the costs of producing both grain and livestock and represent a contribution to the general welfare.

While the resolution of the Ontario Federation stresses "reasonable stability in feeding costs" it also concurs in the fixing of selling prices at a level "based on the free supply and demand situation for coarse grains both in Canada and export markets." The Federation may have anticipated some stabilization in the price of coarse grains as a result of the maintenance of "adequate feed reserves."

There is, in the opinion of the writer, a distinct possibility that it is possible to devise and apply a system of administered prices which will do a better job, in terms of resource allocation, of getting grain and livestock products produced than the open market will do. It is not apparent, however, that such a system has been devised prior to the launching of this present program of state marketing. Western farm leaders do not want state marketing of coarse grains in order to secure a monopoly price for their product. They seem inclined to believe that it is possible to make the Wheat Board the sole marketing agency and at the same time retain the open market as a guide to the Board in fixing initial prices to the producer and selling prices to the feeder. Since the Board in marketing the

western crop will control over 90 percent of the supplies of coarse grains entering into commercial channels for the country as a whole the Board's selling price will determine the market price rather than the converse. Nevertheless, Mr. Howe, in announcing minimum initial prices to be paid producers in 1949-50, also stated that the Board's selling prices will be set from day to day and will depend upon the strength of demand.¹⁴ It might be inferred that Mr. Howe anticipates guidance from the market in setting these prices. In any event prices to feeders will not be forward prices in the sense of being announced far enough in advance to reduce the price uncertainty confronting livestock producers.

The obvious danger is that the buying and domestic selling prices fixed by government for oats and barley will become "political prices." Rather than being established upon the basis of economic criteria, i.e., equating supply and demand, government will be subject to a strong temptation to fix grain prices at that level which will satisfy a maximum number of voters. Pressure may well be brought to bear upon the government by those speaking on behalf of the western producer to fix the price at a higher level; by those speaking on behalf of the eastern feeder to fix the price at a lower level. Caught between these two forces any government may well find that the easiest solution from a political point of view is to satisfy both groups, and, rather than setting one price for both sellers and buyers,¹⁵ to establish two prices and then to bridge the gap between the higher price to the grower and the lower price to the feeder with a subsidy. The Canadian consumer should not prove too unhappy with this arrangement since he would indirectly benefit from a lower price of meats, poultry and dairy products. Having satisfied three groups, the government in power may find it possible to ignore the complaints of the taxpayer who would be called upon to make up any deficits incurred by the Wheat Board on its oats and barley accounts.

Prices determined in this way almost inevitably lead to trouble—and to ever more far-reaching controls. There exists a very high degree of inter-dependence among the prices of our various farm products. If the price of any one of them is pulled out of line by means of controls the effects are transmitted to the production,

¹⁴ As stated in an official press release of July 20.

¹⁵ Or, to be more specific, to make the Board's selling price equal to the price to the producer plus the cost of handling and transportation.

consumption and hence price, of the other uncontrolled products. If, for example, the price to the producer of coarse grains is fixed at too high a level relative to the price of wheat, farmers will seed too many acres to oats and barley and too few to wheat. If the selling prices of oats and barley are set too high relatively to the prices of hogs, cheese, butter or eggs, the output of these products will fall off. The control of coarse grain prices may well lead to control of the prices of those products which coarse grains are used to produce. Canada exports more than one-fourth of her total output of all farm products; she must, therefore, be prepared to produce those products which are in export demand and to sell them at competitive prices. This requirement precludes the setting of a fixed price for a product in Canada at a level higher than the export price unless the government is prepared to subsidize exports.

In the remainder of this paper we propose to examine briefly some of the factors which the government will need to take into consideration in fixing the buying and domestic selling prices of coarse grains. To begin with, it would appear that, since the acreage seeded to these various grains in many sections of the prairies is fairly sensitive to relative price, the relative quantities of wheat, oats and barley desired must be carefully evaluated when fixing the price to the producer. Moreover the price to the producer may not be fixed independently of the price to the feeder, or at least not after storage facilities are filled. The quantities of these grains which the government will wish to see produced will vary with the demand for wheat and feed grains and the strength of this demand must be evaluated in terms of specific selling prices as well as other relevant parameters.

In selling the Board is not obligated to ask the same prices which it pays to the producer, or even to fix its selling prices in such a way as to preserve the same ratio among them as existed among the buying prices. If one of these three grains is overpriced on either the buying or selling side the Board will soon find itself in possession of excessive stocks of that grain. The principle involved in fixing prices so as to equate supply and demand is that of permitting the choices of the ultimate consumer to be reflected back to the producer in order to permit the latter so to allocate his resources as to satisfy the consumer's preferences. If the Cabinet's objective in pricing these grains is to equate supply and demand it seems quite possible, by falling back upon past experience of producers' and feeders'

response to price and by being given some leeway between buying and selling prices through resort to monies appropriated by Parliament, that this objective may be attained. One marked advantage of this method of pricing over that of the open market is that it would permit forward pricing—i.e., informing the producer of the respective minimum selling prices of his grain before he ever puts his seed into the ground.

In pricing feed grains careful consideration will also need to be given the relationship between grain and livestock prices. The output of livestock, dairy and poultry products varies, not only with the prices of these products, but also with the relationship between the prices of these products and the price of feed grains. If livestock and poultry products are to be sold in the open market, supplemented where possible by export contracts, the government will be in control of one of the important determinants of output and hence, indirectly, of price of some, at least, of these products. It is true that the government has more direct means of controlling the price of certain of these products, e.g., by negotiating export contracts for hogs, cheese and eggs or through floor prices for butter. So long as our beef cattle are permitted access to the United States market at prices anywhere near their present level the prices of feed grains will have little effect upon the supply of beef.

In the event that we continue to be able to negotiate export contracts for livestock products with the United Kingdom the selling prices of feed grains might be fixed at a level designed to fill these contracts and to satisfy the domestic market at comparable prices. With reduced contracts and shrinking non-contract export markets for livestock products, feed grains might be priced high enough to reduce the supply of such products to fit these markets. This approach might encounter heavy opposition from the feeders of coarse grains; it might also involve production or marketing controls on grain if supply exceeded demand once storage stocks became large.

However the farm pressure groups on whose insistence this step is being taken do not expect the government to attempt merely to establish "equilibrium" prices. They favor government marketing because they believe it offers a means of reducing cyclical variations in the price of grains. In other words they expect the buying prices of oats and barley to be fixed at higher than market levels during periods of low market prices and, perhaps, lower than mar-

ket levels when grain prices are high. The support accorded the wheat contract with the United Kingdom would seem to indicate that prairie grain producers will accept moderate prices if some degree of longer-run price stability is assured to them.

The necessity of satisfying this further requirement is going to complicate greatly the government's pricing problem. Prices are now to be used as means of reducing those wide fluctuations in farm income which result from cyclical variations in the price of farm products. If during a depression, in order to support or stabilize farm income, the prices of oats, barley and wheat are held at levels higher than those needed to establish equilibrium between supply and demand, it will be necessary either to support the prices of rye and oilseed crops or limit the acreage or deliveries of the three grains whose prices enjoy support. Otherwise farmers will simply fail to produce those crops whose prices are not supported. In the park belt this may also apply to the acreages normally seeded to forage crops where such land may be used for grains.

No provision is made for the accumulation of a fund from the excess of selling over buying prices during periods of high grain prices to be used to keep buying prices above selling prices when grain prices are low. Bill 135 limits the pooling period for coarse grains to one crop year thus preventing pooling over a period long enough to cover years of both high and low prices. Probable deficits incurred by the Wheat Board on its coarse grain accounts during periods of low grain prices will be made up from the Consolidated Revenue Fund while surpluses will be pro-rated back to producers. This means transfer payments from the taxpayer to the farmer over a period of years. One disturbing feature of this policy is that once the open market has been closed there is no reliable way of computing the volume of such transfer payments.

The Agricultural Prices Support Act of 1944 excluded wheat from the products whose prices it might support since this grain was already being marketed by a government agency. In fairness to the western farmer it should be said that he is not supporting government marketing of coarse grains for the purpose of exacting subsidies from the federal treasury. By selling through a pool every farmer will receive the same price for the same grade irrespective of the date within the crop year at which he makes delivery of his grain. Both producers and feeders expect a more stable price of feed grains than under an open market. The first of these two advan-

tages might be secured by means of a voluntary pool.¹⁶ Government storage operations might serve to reduce substantially those fluctuations in price arising from variations in yield. It is by no means certain that a state marketing monopoly is the best means of attaining either of these two objectives.

The initial price which the Government has now decided the Board shall pay for oats and barley is the support price announced on March 15, 1949. Initial prices are thus being used as a means of supporting the incomes of coarse grain producers just as with wheat. Actually, of course, the same farmers produce both wheat and coarse grains. In the event that the Board's initial buying price is higher than its domestic selling price coarse grain producers may prove reluctant to feed their grain to livestock in competition with specialized feeders who can obtain feed grains at a lower price from the Board. There appears to be no practical administrative method of buying feed grains from the grower-feeder at the higher price and selling it back to him for feeding at a lower price.¹⁷

The difficulties of establishing prices for coarse grains which will serve the dual function of equating the supply of and the demand for these grains and at the same time providing stabilized prices in the face of fluctuations in the level of employment and national income seem virtually insurmountable. If the latter objective is considered the more important, resort will likely be had either to marketing or production controls to achieve the former.

This nationalization of the marketing structure for coarse grains may have international as well as national implications. Canada would seem to be falling in with the present trend toward state trading observable in so many other countries. Once the government had assumed the responsibility of marketing Canadian wheat in peace as well as war there seemed no good reason to the farmer why it should not market coarse grains. There may be equally cogent reasons why government should market the beef, hogs, cheese and eggs which are produced from coarse grains.

The economist has a prejudice in favor of using the price system as a means of informing producers what products consumers are willing and able to buy. Many writers on the economics of socialism

¹⁶ The Government has asked the Canadian Wheat Board to conduct a voluntary pool for flaxseed in 1949-50. The initial price is fixed at \$2.50 per bushel for No. 1 C.W. flaxseed basis in store Fort William.

¹⁷ See above footnote 8.

would retain the price system as the most effective means of performing this function.¹⁸ If government control of the price structure for grains is to be used as a means of stabilizing farm income over the ups and downs of the business cycle the implications of such control need to be thoroughly explored. Few would quarrel with the objective. The important question is what is the cost and what kind of by-products come wrapped in the same package with price stabilization. Since the government has indicated its intention of implementing Bill 135 at the beginning of the new crop year, August 1, more of the answers will have been placed on the record before this article is published.¹⁹

¹⁸ See Abram Bergson's essay, *Socialist Economics*, in *A Survey of Contemporary Economics* edited by Howard S. Ellis, Blakiston, 1948, pp. 432-440.

¹⁹ A Canadian Wheat Board statement issued on August 4 and after the above article was written, gives some idea of the Board's resale plans. The Board is not taking over the very considerable stocks of old crop oats and barley which were delivered by farmers prior to August 1st, and which are still in the process of being marketed by the present holders. This means that for some time after the marketing of the new crop begins there will be two classes of coarse grains for sale, the new crop stocks handled by the Wheat Board and the old crop stocks following the open market route. Since most of the old crop stocks have been hedged in the Winnipeg futures market for October and December delivery, open market trading in grain for future delivery as well as in cash grain is bound to continue until marketing of the old stocks is finally completed.

In view of this situation it is not surprising that the Wheat Board should now announce its intention of making general use of the existing facilities including the future trading facilities of the Grain Exchange. At present the Board is offering to sell grain at daily quoted prices in store the Lakehead, both for immediate and future shipment, to dealers for distribution to users. These selling offers are made in competition with the private trade which is marketing the carryover from last year's crop. For the time being at least, therefore, the Board has left the way open for eastern dealers to continue buying as heretofore. It is difficult to see how this open market system can possibly continue in operation once the old crop stocks have been finally disposed of.

THE LOGICAL FOUNDATIONS OF ECONOMIC RESEARCH

KENNETH H. PARSONS
University of Wisconsin

TWENTY-FIVE years ago agricultural economists were deeply concerned over the need for improved methods of research. The efforts in this direction and the assistance of the Social Science Research Council are well known, and need not be recounted here. Whatever else may be said about this effort, it gave impetus to great improvement in statistical methods of economic research, which has been of inestimable value; some of the top flight statisticians of the country are to be found among research workers in agricultural economics.

There is again a deep sense of uneasiness about methods of research in agricultural economics. But now, if I sense the situation correctly, there is little expectation that a well chosen committee might go to some authority, such as Karl Pearson, and find adequate answers to our problems. What has happened, is that now the whole underpinnings of economics itself are open to question. Consequently, just as it is no longer possible to find an adequate research method to apply to our problems, so it is no longer possible to find an adequate "pure" economics to apply to the economic problems of agriculture. Two conclusions seem obvious: (1) that comprehensive methods of investigation must be devised by agricultural economists out of our own investigation, and (2) this presents an unusual opportunity to contribute to economic and social science theory generally if we have the wit to do the job before us.

As I have tried to analyze and understand economic theory and scientific method in economics I have become impressed by both the need for, and the possibilities of, a restatement of our problems in the light of logical theory. Such an effort requires a consideration of the very foundations of methodology in economics. This paper reports a part of an attempt to state the methodological issues in economics by an examination of the relevant issues in economic theory, logical theory and statistics. From the viewpoint of systematic generalization, logical theory is both more inclusive and more fundamental. Consequently this essay takes the form of analyzing the whole complex of issues from the perspective of logical analysis.

I have thought for a long time that the issues in economic analysis might be clarified by systematic recourse to logical theory. For example, it appeared likely that a thorough study of John Stuart Mill's *Logic* might reveal the true theoretical foundations of classical, and possibly neo-classical, economics. Furthermore, I supposed that modern logical theory might help to explain the peculiar directions of modern theorizing in economics. I do not claim to have mastered the several theories of logic or any one of them. But the work of colleagues and some of my students, as well as my own effort, has deepened my conviction that a real understanding of logical theory by economists would greatly strengthen our work in research and theoretical economics. As I have read current philosophical theory, the works of Dewey and G. H. Mead have been most concerned with the issues that grew out of my attempts to understand economic analysis. I therefore set out to achieve sufficient mastery over their works, especially Dewey's, to enable me to examine the methodological issues in economics in the light of their insight.* Although I do not see that the social sciences are quite so primitive as he concludes in his chapter on Social Inquiry in his *Logic*,¹ I am convinced that the basic argument in his logical theory may well prove to be the most profound contribution of modern times to social science methodology.

The General Issues

As we think systematically we make such distinctions as are necessary for accurate thought. Just precisely what the distinctions are in terms of basic issues depends in part upon the general view-

* Most of the specific investigational issues are stated in terms of the problems of the economics of agriculture, the field of my research program. I have tried to test the ideas presented here against the issues as presented by the most diverse viewpoints in economics; but no doubt the particular turn which my thinking has taken has been influenced most by my graduate teachers who left with me countless suggestions and statements of dilemmas or paradoxes—especially I find myself returning again and again to the remarks of Professors B. H. Hibbard, J. R. Commons, and F. H. Knight. From the formal study of philosophy, I owe a heavy debt to Professors Max Otto and Charner Perry. Among my colleagues, I have benefited greatly by the criticisms and comments over the years by Carl Bogholt, Horace Fries, Erven Long, Walter Morton, James Earley, and Martin Bronfenbrenner. Not the least of the stimulus to this attempt to work through the issues in economic methodology have been the pressing questions of my students. Out of that profound wisdom which doubts all things, students manage somehow to keep one forever in that strange attempt to get his feet on solid ground by thinking about things which are over his head. To the participants in the several Land Tenure Workshops sponsored by the Farm Foundation I am also indebted for countless suggestions.

¹ John Dewey, *Logic, The Theory of Inquiry*, Henry Holt and Company, 1938.

point of the analyst. These viewpoints are to be distinguished from each other on two different bases: (1) what we may call the philosophical frame of reference and (2) the degree of generality attempted in the viewpoint.

As to the first, I accept as a working hypothesis for these analyses the general viewpoint most accurately characterized as instrumentalism. I do this out of a conclusion that here better than anywhere else do I find the basic distinctions relevant to social inquiry as practiced by economists. One of the critical issues here is the question of whether or not mind is a creative factor in the social process. Unless thinking can do more than merely reflect "reality" as a mirror, or observe it as an Olympian spectator, there is no possibility of inquiry being creative. Much of the cynicism of modern economic thought comes from the uncritical incorporation therein of a basic assumption that thinking cannot possibly have any fundamental influence on "reality."

One of our difficulties in economics is that the field is so vast that different people are thinking about different aspects of the whole. If someone sets out to analyze the problems of price predictions, everyone, including the investigator himself, should recognize that what he has to say will be only obliquely relevant to questions of economic organization or control. Again, if we are striving for a statement of the conditions of general equilibrium and achieve this by assuming that the critical questions of valuation are all settled, then we should recognize that we have said nothing about valuation except what we assumed in the first place.

In short, our purposes and problems dictate the required scope of analyses. This might seem to be simple but in the present state of economic thought it is indeed a very difficult matter. Not the least of the difficulties is the fact that economic theory is being taught as a technique of analysis without adequate formulation of the relations to the fundamental issues either in a truly general theory of economics, or of the requirements for investigating genuine social problems. We should not, however, minimize or in any way discredit these techniques of analysis. The problem in this context is rather one of formulating the more comprehensive issues so that we can put economic theory to more fundamental tests than logical consistency.

For these and related reasons I have tried to think my way through the issues by relating them to the basic insights of logical

theory. As we do this we find ourselves drawing careful distinctions between fact and idea; and examining the question of whether economic theory is a system of general ideas, inquiring how economic theory is related to hypotheses in investigation, etc. To make and discuss such distinctions we must have some common understanding of the nature of propositions and their relation to judgment; of induction-deduction; of definitions and classification; of the theory of predication; and other elements of logical analysis.

One of the most difficult tasks in all this, at least for one whose primary training is in economics, is to keep clearly in focus the logical nature of the distinctions.

Kinds of Scientific Generalizations: General Propositions

We begin the exposition by accepting the conception that there are two distinct kinds of scientific generalizations: the abstract and the factual.² The validity of this conception will be argued subsequently. Abstract generalizations are technically known as Universal Hypothetical Propositions; generalizations of fact are known in logical theory as Generic Propositions.³ Abstract universal propositions formulate the basic argument of scientific theory, including economic theory. The generic generals state the generalized facts, the established facts, in propositional form. As will be developed in more detail in subsequent sections of this paper, scientific generalizations from investigations of fact can be achieved only by the use of the hypothetical universals. This requires some examination of the actual processes of generalization—of the relation between induction and deduction. Also it will be argued, that the content of hypothetical universals is given by the nature of the problem under investigation.

A proposition is distinguished from a mere social communication by the function it performs rather than by the form. A proposition is an assertion which is grounded in argument and evidence; it is a statement which is a part of a set or series of statements each of which is framed with reference to resolving a question, by pointing

² Dewey, *Logic*, especially Chaps. XIV and XV, pp. 264-310.

³ Readers will recognize the difference between accepting this distinction here for purposes of simple statement of the argument and acceptance of the same as a valid hypothesis for the explanation of scientific theory. The latter is of course the fundamental question. I shall attempt to present the main points of the basic argument for the validity of this distinction—but a complete analysis of the issues would require that we cover the whole field of logical theory. Such is manifestly impossible in this essay.

toward some "cumulative convergence in effecting final judgment." A logically complete proposition indicates its own grounds for validity.⁴

The reasoning back of this assertion that there are two fundamentally different kinds of scientific generalizations will become evident as the argument develops. But I do not want to gloss over the fact that this is a genuine issue. For example, once this distinction is granted the oft repeated claim that a theory is warranted because the assumptions upon which it rests "fit the facts" must be re-examined. Also, new light is shed upon Professor Knight's perennial insistence that great confusion is injected into economic analysis by the erroneous belief that economic theory describes existence.

Professor Frazer maintains that there are not two different sets of propositions, but that two different aspects of the same propositions should be distinguished.⁵ Mr. Hutchison, however, holds that economic theory is so completely separated from generalization of fact that pure theory is simply "verbal"—a set of seemingly independent propositions.⁶

I cite these different interpretations merely for the purpose of indicating the order of issues involved in the acceptance of a position regarding the kinds of propositions. But the issues cannot be argued out now. Here I simply observe that in the argument of this paper, economic theory is considered as falling within the realm of universal hypothetical propositions. Such propositions do not describe the facts; rather the function of these propositions is to "prescribe" the conditions which must be met in classifications of fact. As such, economic theory is an elaboration of definitions, but

⁴ See Dewey, *Logic*, p. 321. Also: "When it is said that 'iron is a metal' the proposition does not appear rational because we cannot convert it simply into 'metal is iron' But the proposition as it stands is not logically a complete proposition. It does not indicate or even suggest its own grounds. At most it is either a sentence communicating information or is a proposition preliminary to further inquiries. The complete proposition is 'Iron is a metal possessed of such-and-such differential characteristics.' Any metal having these specified properties is iron, so that the proposition is logically, not verbally, a proposition regarding a *relation* of kinds" p 308-309

⁵ *Economic Thought and Language*, L. M. Frazer, A. & C. Black, Ltd. London 1937, p. 52.

⁶ *The Significance and Basic Postulates of Economic Theory*, Hutchison, T. W. Macmillan, London, 1938. In critical discussion of the issues involved in this positivistic conception of theory and methodology see Professor Knight's review, "What Is the Truth in Economics?" *Journal of Political Economy*, Vol. 48, 1940, p. 1; and the reply and rejoinder in same *Journal*, Vol. 49, pp. 732ff., Oct. 1941

the definitions are not arbitrary or to be selected at the pleasure of the theorizer. Rather the definitions and theories are elaborated from insights derived from actual existential relations. The solution accepted in this paper is that the two different kinds of generalizations are distinguished by analyzing the function which they perform in inquiry.

There is a fundamental difference also in the way in which propositions within the two types are related to each other. Hypothetical universal propositions come in series; each proposition follows from the preceding. They are related by logical necessity, and may be proved or disproved by logical analysis. Generical generals and other propositions about existences are developed in sets. As the propositions of fact are developed they gradually converge upon the point in question. In the latter, "proof" can never exceed some degree of probability.

Warrantable Statements of Fact

We may go right to the heart of the matter by asking the general question, how does one establish a statement of fact? This question has been answered in different ways; and this variety of answers can be found all through economic literature.

Those who would simply collect observations of particular instances and then generalize from this collection, accept the conception of a fact as given in and of itself ready to be picked—so to speak. So considered, facts are simply data (literally the given). If you follow out the argument of this approach, you come eventually to the conclusion that the basic classifications of fact are (a) either given in nature (the Aristotelian view) or (b) in some form of sensational empiricism such as that the basis of classification is simply in the regularity of the repetition of impressions of the observer. In either case the facts can be known without discriminating thought.

It should not take very much argument to convince any investigator of the fundamental error of the above conception. Facts are not *given*; they are *taken*—taken by a process of selective discrimination. Facts do not just happen, but happenings can be converted into facts. Only "things" just happen. In common speech we more frequently use the negative—as "nothing happened." But stated either way the "given" nature of happenings is suggested. When we attempt to understand "what happens" we use thought to dis-

criminate "happenings" into "events." Again common speech notes this distinction by referring to happenings as "minor events" or "big events" and so on. Inquiry (research) discriminates happenings into events and these are "taken" to be facts, although we frequently *mis*-take something to be a fact which isn't. Events are converted into facts when we understand the relations between them, the conditions upon which their occurrence depends.⁷ Facts are questions answered by inquiry into events. The genius of finding facts is largely knowing what questions to ask.

Fact finding is more than observing what happens. To anticipate subsequent argument, facts are derived by judgment; and judgment is the core of the method of generalization. Regardless of the degrees of refinement in procedure, of sampling or otherwise, ultimately the events are "judged" to be facts. This appears to hold whether we consider few events as on one farm, or a mass of events as in the making of a crop estimate.

It turns out, therefore, that the validity of the facts themselves turns on the methods of generalization. The view adopted and developed here is that particular observations are developed into facts through a process of comparison-contrast guided by a system of definitions—which definitions are a part of the comprehensive system of abstract conceptions.

The Methods of Generalization

(1) The general pattern of inquiry; problem formation and solution.

In any research effort worthy of the name, the attention of the research worker comes to a definite specified focus. We do not just research in general. We investigate something. How that something is chosen is not crucial provided only that the problem is real, not fanciful. In the practice of the advanced sciences, many, if not most, of the research problems are set by discrepancies between observed occurrences and previously accepted explanations. But

⁷ In Dewey's statement: Facts "are selected and described . . . for a purpose, namely statement of the problem involved in such a way that its material both indicates a meaning relevant to resolution of the difficulty and serves to test its worth and validity," *Logic*, p. 113. Or in more general terms: "The objects of science . . . are an order of relations which serve as tools to effect immediate havings and beings"—John Dewey, *Experience and Nature*, Open Court Pub. Co. 1929, p. 136. Again: "Knowledge . . . signifies events so discriminately penetrated by thought that mind is literally at home in them." *Ibid.*, p. 161.

many of the problems studied by agricultural economists, at the state Experiment Stations at least, have been those posed in the first instance as immediately practical problems of farmers. For purpose of exposition here we shall direct our thinking to the formulation of a procedure in terms of analysis of an immediately given problem at the farm level. But however theoretical or immediately existential the problem, the ultimate test of a valid solution must be the final explanation resolving the doubt, or answer to the question. This is checked by acting upon the conclusion; the final test for all sciences short of (in terms of abstractness), or other than, pure mathematics is practical relevance.

(a) *The situation; confused—problematic.* Perhaps everyone who has worked in a state Experiment Station has had the experience of being confronted with an assignment something like this: "Something is going wrong out at Silver Creek," or "The farmers can't get any help," or "Their farms are being foreclosed," or "The livestock are coming to market in bad shape," or "The cooperative is about to go bankrupt," or "What was once an active rural community is now dead," etc. The details are infinitely varied, but the common import is a situation of confusion, doubt, tension.

The first thing to get clear is whether or not the confusion is in the situation. If it is, this gives an objective base upon which to work. From this situation a problem is gradually defined. But there is a vast difference between a confused situation and a problem. What intervenes is the first stage of analysis—defining a problem. A problem is essentially that aspect of the situation which if modified will correct the difficulty. In short, the problem is the limiting factor in the reconstruction of a situation. The solution of a problem must be conceived of as in some way related to the potentialities of the situation—the accessible or available alternatives. But the situation is not all confusion, otherwise investigation could scarcely be fruitful. The problem has to be set off against the stable parts of the situation which can be taken as reliable or dependable.

There are two closely related but separable issues in the conception of a problem. The *nature* of a problem and the logical function of problem solving. It is important that we conceive of the nature of a problem in some way which actually *admits* of solution. It is very common practice for economists to attempt to treat "problems" as the discrepancy between the actual situation and some

"ideal" assumed to be the relevant solution.⁸ Under this conception of a problem the "solution" is simply a priori and arbitrary without regard to available alternatives in the situation.

In the context of the present argument, however, the role of problem solving as a method of verification is the more critical consideration. The crux of the issue is simply this: that the only alternative which we have to the validation of inquiry by problem solving is a reliance either upon the self evidence of fact or principle as the foundations of knowledge—or upon revelation. Both of the latter alternatives are incompatible with a genuinely scientific viewpoint. It is the recognition of this point, I infer, which leads almost everyone to talk about problems and problem solving, regardless of viewpoint or of the way genuine problem solving fits into their implicit theory of knowledge.

But if one is to conceive of problem formation and solution as a fundamental part of inquiry the actual procedures of investigating a problem need to be conceptualized. To return to the instance of investigating an immediate problem, when the investigator is handed the assignment he likely looks first for analogies.⁹ Gradually he begins to assemble some possibly relevant facts already known; number of farms, or kinds of livestock, or the history of a school or a church, etc., depending on the situation being analyzed. Correlatively he takes a provisional inventory of explanations previously given and generally accepted; then if he is wise he will pick up unaccepted, even seemingly foolish, suggestions. The known facts are the raw materials of the "facts of the case" and correlatively the explanations are the beginnings of the hypotheses to be formulated as a solution to the problem. So far all this is general and preparatory; the facts and suggestions are provisional—provisions for the explorations, in the literal sense of the term provision. If similar problems have been investigated before, and the procedure is well established, the investigator will have available a large body of facts, presumably relevant, and a comprehensive

⁸ See for example Gale Johnson's "Contribution of Price Policy to the Income and Resource Problems in Agriculture," this Journal, Vol. XXVI, No. 4, November 1944, p. 631ff.

⁹ This is one place for the method of analogy—sometimes treated as a separate method. For example, "Research Method and Procedure in Agricultural Economics," Social Science Research Council, 1928, pp. 15 and 298. The position taken here implies that the use of analogy is simply a distinguishable phase in a continuous process of research. This is essentially what the authors of "Research Method" also intended.

body of theory which will serve as the matrix for the hypothesis for this particular investigation.

But the actual inspection of the situation is something different. Here one sees at first, say, farms of different sizes and qualities, occupied by persons of varied ages and capacities, etc.—in short, a cluster of unique events. The first stage of the actual exploration or inspection is to note the “qualities” of things. You talk to first one person and then another—just visiting but thinking all the while. You visit some more and “compare notes.” The notes you compare are simple assertions, each one rooted in an observation. Assertions of this order are simply statements regarding observed qualities but they don’t “make sense” as we say. In terms of logic the assertions are “particular propositions.” They may be interesting but they are scarcely instructive.

So far we have noted only qualities. The observations of qualities make sense only when qualities are taken as the “traits” of something. The observed qualities become evidence, as evidential traits. Or as we say quite accurately in common speech, “I saw this but what does it mean?” When qualities become the signs of something, they take on significance.

Here is the root of the necessity for hypotheses, theories, systematically formulated concepts. For a quality to become a trait, or a sign, it must be related to some systematic system of concepts.

In exploring the situation further, the investigator may suddenly “get an idea.” He sees a possible connection between “particular” assertions. This connection when analyzed is stated as a conception; subsequently, if the analysis prospers, the conception directs further comparisons and contrasts and the situation begins to clear up. In systematic inquiry the hypotheses guiding a particular investigation are elaborations of suggestions rooted in some “growing point” in a comprehensive system of theory. The “meaning” of the facts in this problem then merges, through discourse, with the general system of guiding theory.

In terms of logical theory, the particular propositions are converted into “singular” propositions about connections among things. These singulars when classified into a comprehensive generalization take their place as members of a kind, and are then comprehended by a more general proposition—the generic general. The farm machinery rusting out-of-doors becomes a sign of a neglectful farmer; which in turn is one of a larger class of farmers

who are likely to have high costs in relation to returns, or permit their farms to erode, or their livestock to become diseased, or their children to become truants. What the quality becomes a sign of depends in general on the purpose and context of the investigation, and in terms of procedure, upon the hypotheses that are then operative in inquiry.

The hypotheses formulate the alternative possible solutions to the problem and are tried, reshaped, rejected or then finally accepted as the best explanation possible (under the circumstances).

In terms of a problem, the problem is not clearly formulated until the possible solutions are systematically stated. The problem is resolved by testing the several hypotheses, as possible explanations when used in conjunction with the facts—both the facts of the case brought into the analysis from previous studies and the facts produced in this specific inquiry under the guidance of the very hypotheses for which the facts are evidence.

It is much easier to see from our experience how the formulation of a problem suggests the solution than it is to comprehend the deeper insight that a problem is not formulated until a solution is projected. Instances abound from the work of agricultural economists to illustrate how the formulation suggests a subsequent solution. It was in the early 'twenties, I believe, that the index of the prices of things farmers sell and the index of the prices of things farmers buy were published in parallel fashion in the *Agricultural Situation*. On the surface this appears to be within the conception of Say's law that goods exchange for goods. But this publication undoubtedly gave great impetus to the practical solution which set out to achieve "parity" prices for farm products. Similarly, Professor Knight's formulation of "uncertainty," which was devised as a part of a rigorous statement of the theory of distribution, when taken to represent a "problem" in agriculture leads directly to the solution of "forward pricing" as a method of solving the problem of uncertainty in resource use.

Clearly, then, the formulation of a problem is a gradual process—in which events are converted into relevant facts, and facts are taken, or discarded, as evidence. This requires a continuous shifting back and forth from clearer evidence to refinement of hypothesis.

(b) *The logical function of schedules.* Somewhere in this process of

investigating a situation, if a field survey is to be made a field schedule has to be drawn up. A real schedule differs from a mere listing of observations simply in this: that in the schedules qualities observed are treated as traits of something. And they are traits only in so far as the problem has been thought through. It is therefore not surprising that rarely, if ever, is a schedule found to be completely adequate. This also indicates why some of the most revealing observations in a study may be those written in the margins or on the back of the schedule. They are notations of qualities which are found upon further analysis to indicate significant traits. The reason may be equally evident for the crippling or blinding effect of stereotyped questions on a schedule imported from previous studies. Questions on schedules, to be effective, need to be components of a system of concepts which have been thought together with specific reference to the problem at hand.

(2) *Induction and deduction.*

It is a commonplace that induction and deduction are both necessary in systematic inquiry. But what is meant by the two operations, independently and conjunctively, is less frequently explained. Although the two processes are so mutually involved as to make inquiry impossible without both, the inductive function will be examined first.

It is generally agreed that induction is the process by which generalizations are arrived at. The significant questions turn on *how* this is done. In the viewpoint incorporated in this paper,¹⁰ the critical point in induction is the transformation of a particular into a singular. The active process of generalization centers here and amounts to the construction of a singular from a particular.

An illustration may help make this point more understandable. A farmer is operating a relatively small place, yet seems to be making a good income without extraordinary effort. As an instance he is unique—in common speech we say, “he is in a class by himself.” This of course is logically equivalent to saying that he isn’t in a “class” at all. But a farm management survey will classify him. How? If meaningfully, it seems to me, the researcher will seek out the connection between the many elements in the farm in such a way that he has some idea of how this same set of “attributes” can

¹⁰ See Dewey, *Logic*, Chap. XXI, Induction and Deduction, especially pp. 248–252.

be reconstructed. The investigator will have ideas of the way things are involved together on this farm so that he can direct the way in which other farmers may be able to do likewise. When the analysis has proceeded as far, then this original unique farm combination, this cluster of events, becomes the ground of the construction of a *singular* case which is one of a kind (shall we say efficient, high-labor-income small farmers). But the point is that generalization from this particular case is based upon the possibility of reconstructing the essential relationships for a singular. Consequently the generalization is possible only through the instrumentalities of the hypotheses which directed the analysis, by formulating the "possibilities" by which the "potentialities" of the involvements were analyzed.

The inductive process, then, moves from particulars to generals by the formation of classes, through controlled institution of singulars (to use the logical terminology). But classifications are worked out only with definitions; here the cooperative, or complementary, nature of induction-deduction is clearly evident.

Deduction is a chain argument. In deductive thought there is the development of implications through a series of statements, each of which is related to the other in a logically necessary way. Grant the initial proposition and you are forced to accept the others, simply because all are implicit in the first.

The function of deduction in the process of generalization is to develop the implications of certain relations. More specifically a chain of reasoning develops a series of propositions, a theory; this theory is an inclusive set of definitions used in the investigation. These definitions work out in rigorous fashion the interrelation of characters. For example, in "a perfect market . . . all the buyers and sellers in it have perfect knowledge of demand, supply, and prices and act rationally upon that knowledge."¹¹ These characters of a perfect market are so interrelated that all must be embraced within one general conception. Each is implied in the other. The binding together by implicatory reasoning of such concepts as the market, supply, and consumption into a logically consistent system is economic theory. The deductive function in generalization elaborates an appropriate possible set of definitions, which set is gradually whittled down by trial—gradually reduced to the one best definition for the investigation of that time and place.

¹¹ Shepherd, Geoffrey S., *Agricultural Price Analysis*. Collegiate Press, 1941, p. 31.

(a) *Classifications—definitions.* Classifications of relations into mutually exclusive classes are possible only on the basis of complete definitions. The aim of an exhaustive classification, on a given relation, or set of relations, is to classify the (existential) events into mutually exclusive classes—with all of the cases included; the classes total 100% of the universe. Essentially these classes are additive. But such inclusive-exclusive classes, based on characteristics, can be formed only on the basis of definitions in which the relevant characters are worked together by discourse in such a way that the essential interlockings are clearly defined. The definition or system of definitions points to a conjunction of traits. If the particular instance fails to qualify on *all* of the specified traits it is not placed in this class. The *characteristics* are classified according to the way the *characters* are related in the definition.

(3) *Generalization through judgment.*

Scientific inquiry has for its purpose the increase of knowledge or enlargement of the domain of fact. Upon this there is general agreement. But one crucial feature of this process has not been generally recognized by economists, I believe; namely, that the actual finding of fact involves a judgment, which judgment has parts which can be analyzed according to their function. One of the central theses of this paper is that this judgment function needs to be analyzed as a part of the methodology of economics.

In "pure" economic theory there are no judgments, just an interminable series of propositions, a system of implicatory relations. At this limit of "purity," however, economic theory becomes one with mathematics. Since economic theory must have some "economic" content (to be discussed later), we find that theorizing in economics always takes a direction according to the purpose of the investigation. The "purpose," in terms of methodology, is actualized through judgment.

The kernel of the idea is simply this: that all judgments when cast in the form of a syllogism have a theoretical major premise and a factual minor premise.¹² Functionally, then, theory operates through judgment as the major premise; it is here that theory is tested—when tried in the crucible of judgment.

¹² See *Logic*, for example, Chap. VII, and Chap. XIII. The exposition here follows the general conception by Dewey but is stated rather loosely to convey the general idea without careful attention to the nice distinctions of technical logical analysis.

I have used the term judgment and the syllogism as synonymous: this requires some explanation.¹³ Technically speaking the judgment takes the form of subject and predicate. Through judgment we predicate something of the subject. The subject is a factual something—which marks off some part, some potential, of a situation; the predicate is an idea which states (implicitly) some plan of action for realizing possibilities. The statement of ideas (theory) elaborates the possibilities of action; the assertions of fact state the potentialities of a situation. A judgment brings the possible and the potential into consonance through narrowing down the range of the possible to that which can be conjoined with the available potential.

It is therefore through the "predication" process that the area of knowledge is expanded. A subject whose known *potential* has been expanded by fusion with a wider range of the *possible* actually increases in potentiality. It follows too that it is only through the use of theory that the actual field of knowledge is expanded. We whittle away at the unknown first through exploring the possibilities through speculative reasoning and then occupy the territory through enlarging the known potential by the expansion of the coverage of existential propositions—statements of fact.¹⁴

The subject of a judgment is not just any statement of fact. Out of the total situation those facts are selected which are relevant to the problem at hand. Similarly propositions of theory are not moved like counters into the predicate function. Instead the major conception which gives most promise of being relevant as an "explanation" or "solution" is taken as the initial point of the chain of discourse. "Does the elasticity of demand have any bearing on the possibilities of production control?" Or, "Does the willingness with which people join organized activity influence the functioning of an organization?" From such general conceptions as "elasticity of demand" or "willing participation" the investigator elaborates a series of propositions toward the relevant problem. This is, of course, an extremely difficult task.

¹³ "The syllogism is the form of the conjugate connection of the factual and conceptual subject-matters of judgment, stated in such a way as to indicate the conceptual and observational conditions to be fulfilled if judgment is to be adequately grounded. Interpreted in this way, the 'utility' of the syllogistic form resides in the fact that it serves as a check in the case of specific judgments, holding up the logical conditions to be satisfied." Dewey, *Logic*, p. 327.

¹⁴ In these remarks I am limiting the illustrative reference to scientific judgments; formally all judgments are similar but I defer comment on practical judgments until later.

Technically, it may be that all that is required is the elaboration of concepts into a complete idea—complete enough to “explain” the problem. An idea is not just a word, or a copy of some “thing” as Locke thought. An idea is a plan of action. “Ideas are anticipated consequences (forecasts) of what will happen when certain operations are executed under and with respect to observed conditions.”¹⁵ Therefore the conception is not really an idea until it is elaborated into a procedural means.

Through the continual testing and trying, by sifting the factual evidence to find the relevant, by arguing back and forth through a system of conceptions, the factual and the ideal, the subject and the predicate are brought into correspondence with each other. “There must be some one *question* to which both the subject ‘this’ and the predicate are relevant.”¹⁶

Generalization, then, is not grounded in the nature of things, but in mode of response to the investigator. Professor Dewey stated the essence of the problem of generalization in a powerfully simple way. “We are brought to the conclusion that it is the modes of *active response* which are the ground of generality of logical form, not the existential immediate qualities of that which is responded to.”¹⁷

Thus far, we have attempted to work through the theory of scientific inference and generalization in economics by analyzing the nature and function of propositions and judgments. It is now proposed in the remainder of the essay to carry the argument into the consideration of three fundamental issues in economic research: the nature and function of economic theory in inquiry; the distinction between pure and applied economics; and the problem of classification in statistical analysis. Obviously each of these vast topics must be treated with utmost brevity; however, it may be possible to indicate briefly the way in which the basic issues are related to the theory of inquiry under consideration.

The Logical Function and Status of Economic Theory

Everyone seems to agree that economic theory is a logically consistent body of propositions. Theory is expanded or developed by rigorous attention to implication. The implications of rigorously

¹⁵ Dewey, *Logic*, p. 109.

¹⁶ Dewey, *Logic*, p. 126.

¹⁷ Dewey, *Logic*, p. 252

formulated insights are elaborated into a system of conceptions by deductive reasoning. Furthermore, theory is developed in blocks which may be integrated into a unified body of argument by developing common major premises from which the various propositions are deducible as implications. The fundamental major premises are postulates, which are chosen on the basis of adequacy of function in giving unity, power and direction to the theory.

It is also quite generally agreed that no one can be a really top-flight economist without having thoroughly mastered the theory which is relevant to his field of work. But when one inquires just what relevance means, he will find much less agreement. Indeed one can scarcely maintain that there is any substantial agreement on the fundamental reasons of *why* and *how* economic theory is relevant to either research or practical action. I do not propose to make any survey or evaluation of the reasons given or acted upon by economists in this context. Instead, I shall attempt to state the argument for the logical function of economic theory within the general conception of inquiry hypothesized in this essay.

It seems clear that economic theory has its primary function in assisting economists to think clearly and accurately; i.e. the basic function of theory is methodological. This is explained, according to the general hypothesis of this paper, by the double fact that (1) economic theory provides the major premise, the ideal content, of scientific economic judgments, and (2) theory is the method of exploring possibilities (the logical function of predication).

Within this logical conception, economic theory is recognized as being a body of abstract propositions, propositions which function in inquiry as abstract universals in judgment; that is, as providing the categories which determine what factual material can serve as evidence in inquiry.

It will be recognized that economic theory in this sense is not equivalent to general economics. General economics contains different kinds of generalizations which have differing relations to inquiry. Furthermore, when one examines the question of "pure vs. applied" economics, as we do in the following section, it becomes clear that a proposition may function, in identical word form, either as an idea or as a fact depending upon the context and purpose of judgment. However, there are very cogent arguments for the position that only by the analysis of the logical function and status of economic theory can one clear up the current confusion about theory.

It seems clear, on logical grounds, that economic theory does not describe facts or "reality." Theory is a necessary part of the method of describing or classifying facts but it functions as a system of definitions which provides the logical foundation for classification. Theory *prescribes* what is relevant rather than *describes* what is present. The hard facts of the matter are that since the time of Darwin, natural categories are intellectually inadmissible; Darwin pulled the stakes for all humanity and we must henceforth recognize that the world is a process without fixed entities and natural classes. It follows therefore that the only way in which reliable classes can be formed is through the systems of theoretical reasoning by which the categories of thought serve as the bridge between our purposes and the universe as experienced. In this way the classified facts function as evidence. It follows also that one's system of economic ideas determines what is economics to a person, through the selection of evidence. As Boulding has remarked, "The first task of economic analysis . . . is to select from economic events and facts those elements which are significant in relation to the general scheme of economic analysis itself."¹³

In a general way, then, economic theory is simply the system of ideas which economists have derived as a part of the efforts to understand the economic problems of mankind. The content of the system of ideas varies therefore according to what economists consider to be the economic problem: the production of wealth, the business of life, the making of a living or getting rich, the maximization of the utilization of scarce means, etc. But the common ground of all these interpretations (and despite their differences they have much in common) is what we may call the "meaning" of the economy to economists. The general definition of economic theory, therefore, would seem to be about this: "Economic theory is a carefully reasoned statement of the meaning to economists of (that part of) the economic system investigated."

The conception of economic theory as a specialized system of meanings permits the placing of the theoretical concepts of economics in the more comprehensive system of meanings. The meanings of economic efficiency, private enterprise, individual initiative, and collective economic action are surely an integral part of some conceivable comprehensive system of meanings of the American way of life, for example. Similarly, the conceptions of efficient pro-

¹³ Kenneth Boulding, *Economic Analysis*. New York, Harpers, 1941, p. 6.

duction, private property and economic freedom, for example, are an integral part of some conceivable system of meanings by which an independent farmer guides his career.

I do not see that economists have much choice in the matter of how theory functions in thought. If one is to think accurately and scientifically about any point, one must have the control that can come only from an elaborated system of guiding conceptions. If one doesn't acquire these systematically he just "picks them up about the place," as we say in common speech.

*Pure and Applied Economics: Or Scientific and Practical
Judgments*

We turn now to a cluster of issues in economics which are so involved and difficult that any frank discussion of them must be experimental. But the need is urgent and we shall hazard a few comments in the hope that the implications of the previous argument may yield some insight here. Not the least of the difficulties in dealing with "applied economics" or "practical judgments" in economic affairs is that basic issues of valuation are ineradicably involved herein.

I am driven to the conclusion that the distinction between "pure and applied" economics, like that between "pure and applied" science generally, must be abandoned as a general principle. The distinctions made are usually important, but at bottom they confuse the issues.

To accept the distinction between "pure" and "applied" economics as generally valid and fundamental is not only to accept the view that "theory" in its pure form can have an independent career but that it can be validated in some way other than by "application." Furthermore, to accept this distinction as fundamentally valid is to accept the view that the "application" of theory can actually define or demarcate the real practical problems and serve as the source for practical wisdom. To recur to the argument of the earlier part of this essay, the only alternative to some sort of "practical" test of validity in inquiry is the resort to "self-evidence" or revelation.

I do not see how anyone can deny even for physical science research, that the overruling purposes which give the general direction to investigation are rooted in the general needs or problems of the society which supports (or even permits) these inquiries. This

is more obviously true for social science inquiries since the evaluation issues are so much more intrinsic to inquiry itself.

Yet there are fundamental differences here which need to be honored. An alternative formulation, and one which is believed to be consistent with the general thesis of this essay, is to distinguish scientific from practical judgments. Here the distinction turns on content rather than method.

Scientific inquiry has for its purpose the discovery of fact; by rigorous methods of inquiry we gradually discover the underlying connections of things upon which occurrences are dependent. Furthermore, scientific procedures are designed so as to be a part of a continuum of inquiry. A crucial part of this method is the recurrent and repeated formulation of judgments. Scientists hazard judgments for example, that a specific vitamin affects the functioning of an organism in a specified way; or that the savings function operates in some specified way in capital formation; or that diversification of enterprises will increase labor income. Are the judgments correct, or correct enough to be acted upon with reasonable safety? Well, we have to see "how things work out" when we act upon the assumption that they are correct.

There is a vast difference between these scientific inquiries and the practical judgments found in such diverse acts as everyday choices of living or the grand strategy of public policy. These practical judgments have as their purpose the use and enjoyment of things. They are concerned with the way the potentialities of existence are made to serve mankind.

I doubt whether there is another issue of equally grave importance confronting agricultural economists in America, as the distinction between scientific and practical inquiry. Let no one doubt that fundamental scientific inquiry into the economic problems of agriculture is the foremost task of agricultural economists. However, the problem-solving approach to inquiry, which is built into the very structure of agricultural colleges, easily and naturally frays out into a mere servicing of practical judgments. In fact, it requires strenuous intellectual effort to avoid this very outcome. Under such circumstances we gradually drift into an acceptance of the "problems" as formulated by our consistency. The next step is simply that of making "investigators" the mere tools of various interests. All this may be a very pleasant and even an exhilarating experience for awhile, but from a professional viewpoint

it leads to the "consumption of our seed corn" if we may use a good homely phrase.

Yet the issue must be faced. The argument seems inexorable, that there is no other alternative in genuinely scientific inquiry to having both the roots of inquiry and the final tests of validity in practical problem solving. The argument seems to lead us to this point: that the validity of scientific judgments is ultimately established through the "improvement" which such judgments can make in practical judgments. This follows from the admission (1) that the judgments are the critical acts in the utilization of scientific findings; and (2) that the ultimate validity of scientific findings is to be established by practical use.¹⁹

The acceptance of such a viewpoint leads to some novel and difficult problems in economic analysis. Among agricultural economists, or any other group of economists who have a field of specialization, (which includes virtually every one of them) distinctions between scientific and practical are made as a matter of daily work. But there is a strong probability, I conclude, that our efforts are being frustrated and our work reduced in quality because we are intellectually confused on these basic issues of pure or applied; or scientific or practical.

As a suggestion on how we might resolve the issues, we should recognize, first, I believe, that practical judgments have essentially the same form as scientific judgments; namely, that the major premise is theoretical or ideal, the minor premise factual. The facts of a practical judgment, when put in propositional form, are statements of the way things are involved together in the opportunities and obstacles which are relevant to the course of action proposed.

The generalized formulation of these facts, of the way existences are involved together, is the task of scientific inquiry. The facts established by genuinely scientific inquiry are also the general facts of the case for a practical judgment in a specific situation.

¹⁹ The statement of the argument of this section of the essay is made in terms of the relation between scientific and practical judgments in order to bring into sharp focus the operational character of, and fundamental similarities between, all kinds of inquiry. It is implicit in the argument, however, that scientific and practical judgments are related to each other through the reciprocal utilization of the products of each. Scientific judgments produce generalizations; these generalizations are the general and basic ingredients of practical judgments, but reciprocally the validity of the propositional generalizations of scientific judgments is tested by the effectiveness with which they can be used to improve practical judgments—which judgments are directed to the development, use and enjoyment of resources.

A more particular investigation can discover the facts peculiar to the particular practical judgment.

The unsolved or neglected problem in this area of economic analysis is the investigation of the ideal content, the theoretical principle, which forms the major premise of practical judgments.²⁰ Surely the ideas which guide conduct in practical economic affairs and policy can be the subject of investigation. And their discovery and formulation are both an essential part of economic investigation and the bridge, as I see it, between scientific and practical judgments in economics. To be sure there is the question of to what extent practical judgments, including policy decisions, are economic in focus and content. But even this point seems covered by the present proposal: if the problem embraces many different aspects, then both the relevant ideas and facts will be diverse and complex. The ideas will have to be integrated and the sets of facts carefully coordinated to provide a basis for dependable judgment and action. But the contribution of economic analysis to the judgments is still of two sorts: (1) the ideas, philosophies or principles which operate in the major premises of judgment (or the predication of reliable possibilities) and (2) the economic facts which form a part of the minor premise (or subject) of judgment.

It may be obvious that such a possible treatment of principles, or ideas as major premises, faces the valuation problem in two different ways: (1) by formulating the ideas which guide action we open up the possibility of allowing for a plurality of values; and (2) it suggests that ideas as plans of action are the genuine objects of valuation.

Viewing the whole matter in logical terms, then, we seem to have three different kinds of generalizations in economics, even though on logical grounds there are but two kinds:

- (1) the generalizations of economic theory
- (2) the principles of conduct in economic affairs
- (3) the generalizations of economic fact.

In terms of logic, the generalizations of economic theory always appear to function in economic inquiry as abstract hypothetical universal propositions. The generalizations of the facts about the way

²⁰ It is the systematic formulation of the ideas which guide practical action which I understand Allin to mean by *practical theory*, in his stimulating essay, "Theory, Definition and Purpose," in the August 1949 number of this Journal.

existences are involved together are generic propositions.²¹ The generalizations of principles of conduct are investigated (and investigatable) as facts in scientific inquiry but function as abstract propositions in practical judgment.

Unless I am badly mistaken the ideas as plans of action or principles of conduct have not been investigated and cannot be investigated under guidance of equilibrium economics. Formally the issues are met in the purely theoretical formulation by assuming rationality of economic behavior and efficiency as the sole value. Practically under this conception of economics we damn people for being so foolish as to be irrational and say in effect that if genuine valuations can be investigated, at least it is beyond our field.

Any investigation which is guided by rigorous adherence to a mechanical equilibrium theory will, as a matter of course, find only quantitative facts. The "quantities" will be facts of course, but they will be facts which for the most part when related to action will describe or measure the obstacles to action, the resistances to be overcome; the material to be handled, etc. In our careful statements on matters of policy or action we speak about the "effects" of policies, institutions, and activities upon the described system of prices and production. No one who has given any thought to the matter would deny that these are facts of inestimable value. But the actual courses of action are beyond the pale of such investigations.

The suggestion of this essay is that if we are actually to implement and improve practical judgments the ideas at work in such judgments must also be investigated. Nor is this a wholly novel suggestion. Agricultural economists, for example, have had much experience in such investigations. There is, I believe, a great opportunity to improve these investigations; and on the negative

²¹ In terms of content, the range of generalizations of fact would depend upon one's conception of economics. As I read the record, the generalizations of economic fact which have been produced under the guidance of modern equilibrium theory, have come to be considered almost exclusively as facts about the operation of the economy. This seems to me to impose a most unfortunate limitation upon systematic economic analysis in an age when the whole fabric of the social and economic organization of the world is being transformed by negotiation, diplomacy, revolution, taxation and public spending. The generalizations of economic fact, then, need to be viewed as including generalizations about the economy as an organization of human relationships as well as generalizations about the input-output, cash income and price relations, etc. in the operation of the economy. Nevertheless the logical status of such generalizations would be identical, namely generic generalizations about the way actual existences are involved together.

side, the pressure of "modern" theory has tended to rule such investigations out of scientific work.

The raw materials for investigating conduct are everywhere about us wherever people act volitionally. In farm management this means the analysis of "practices"—where practices are what people do regularly in operating farms. It is the practices, as acts, that put a concern together and keep it together. The principles of conduct are simply the "meanings" of these practices generalized into some "ideal" of practice.²² Similarly in all sorts of collective action, the working rules of the organization are the "ideals" derived from the critical analysis of practices. In such cases the "rules" are the principles of joint conduct, which are at once rules for settling disputes and an expression of the purposes of the organization. If one analyzes "conduct" in public policy for the purpose of discovering principles, he would likewise study the practices of statesmen, politicians, administrators, etc. The common ground of all these "principles" is evidently the conception of ideas at work, with ideas conceived of as plans of action taking into account the accessible alternatives among the opportunities and obstacles of such situations.

Here also is the crux of the value problem in economic behavior. Evaluation is inescapably a function of practical judgment. And it is evidently in the guiding ideas in such judgments that the principles of value are explicitly formulated. That is to say, generally speaking, the analysis of valuation must center on conduct and not on values as discrete things. In individual conduct we evidently should appraise alternative ways of doing and living in terms of the consequences for general well being of the individual. In social affairs the analysis of valuation would center upon the rules by which persons work, live, and play together. These rules would be appraised in terms of the effectiveness with which they promoted, say, peaceful, orderly and creative living, and efficient production.

²² I do not want to suggest that the derivation of these meanings is altogether a simple affair. In my own experience I have found any such effort to be both difficult and baffling. In our study, *Keeping the Farm in the Family*, Parsons and Waples, Wis Exp Sta Res Bul. 157, 1945, we attempted to analyze meanings as guiding principles in transference of farms from one generation to the next. At about the same time John F. Timmons working on a study of inheritance in his Ph.D. dissertation formulated the strategic relationships in the devolution of property as "purpose-practice-consequence." He was attempting to formulate something like principles of conduct in the general field of inheritance. See John F. Timmons, *Social and Economic Aspects of the Devolution of Agricultural Land Through Descent, Will, and Gift (A Study of Agricultural Land Inheritance)*, Library, University of Wisconsin, 1945.

But methodologically the point is that these principles would be analyzed scientifically as principles of conduct, and acted upon practically as the major premises of judgment of conduct.

Such interrelations of scientific and practical judgments as indicated raise many questions about the function of economists in practical affairs. It is doubtful whether we are far enough advanced in our scientific work to warrant a complete separation of function. Perhaps economic affairs may always be so complicated that the truly scientific investigator must also assume intermittently the responsibilities of practical administration and judgments. At any rate every investigator in economics even to be scientific—according to the argument of this essay—must somehow think and work his way through to some possible validation of his inquiries in the practical judgments of policy and conduct. There appears to be no other way to avoid mere dallying with make-believe problem solving.

I should like, however, to call attention to the fact that this particular formulation carries with it implications of very profound change in the orientation of our thinking about both economic theory and policy. So far as I know these particular suggestions are new in their reference to economic analysis. This should in itself serve as adequate warning about the possibilities of error in them. But having mentioned the possible dangers, I want to affirm the possibly great advances in thought which such distinctions may hold.

The issues at bottom are nothing less than the question of whether and how valuations may be investigated. The present argument contends that they can be investigated and suggests that the source of evidence is in the practices, the actual performance of persons in the relevant situational contexts.

Furthermore the view that economic theory is simply a part of our methodology would cut the heart right out of the use of economic models as criteria of public policy. (This does not touch the question of the use of models as instruments of investigation.) One of the important implications of this distinction between scientific and practical judgments is that public policy proposals must be formulated as possible ideal guides to practical judgments about policy matters. The prevalent practice among orthodox-minded economists of setting up some model of perfect resource use and then assuming that this is the proper criterion of policy would

have to be abandoned—as a method of getting policy criteria. Judgments of public policy like any and all other practical judgments must be formulated with reference to possible courses of action within available alternatives under the circumstances of the situation. According to the view of this essay it is a part of the task of scientific inquiry actually to analyze and formulate the problems of public policy. Problem-solving is essentially the removal of the troublesome factors in a situation which are the source of the confusion, difficulty, insecurity, etc. Problem-solving removes the blocks which obstruct orderly and satisfying activity. When problem-solving and evaluation are formulated as a part of the functioning of practical judgments, it is obvious that a profound break is implied with the present practice of setting up perfect models as criteria which are arbitrarily assumed to be relevant standards of judgment in the situations. In the latter view, the problem becomes the discrepancy between the actual situation and the assumed ideal. The “solution” then turns out to be some project which would bend “reality” to conform to the model.

The relationship between scientific and practical judgments represents essentially the division of function between research and extension in the Land Grant College system. This function should be one of reciprocal complementation. Such a relationship would seem to be the natural outcome of viewing scientific economic research according to the thesis of this essay. If the task of scientific economic research is conceived of as the discovery of the ideas and facts which are relevant to, and effective in, practical judgments, then there can be neither complete separation of research and extension nor any possible conflict between these functions. The research investigator is interested in these ideas as guides to action and the relevant facts as a matter of truth discovery; and the research cannot, on scientific grounds, be said to be completed, as fundamental research, until the conjoint functioning of these guiding principles and relevant facts are understood in their mutual interrelations. The extension worker is interested in the same findings, but he uses them to suggest improvements in the practical decisions of farmers for converting resources into uses and enjoyment.

The Problem of Classification in Statistics

The classification of data is one of the key points in statistical analysis; it is through systematic classification that the vast masses

of material are reduced to forms in which they can be compared, analyzed and even comprehended. The question, therefore, of just how classes are defined is a strategic problem in the whole theory and process of inquiry.

The most common answer of statisticians to this question, judged by recognized textbooks in the field is that the data are classified by characteristics or attributes.²³ But if one inquires, "Which characteristics and why?" the explanations are not very illuminating; however Bowley²⁴ at least, does work out the argument in a way which permits an approximate joining of the issues with those of logical theory. But the main point here is not to try to comment on the adequacy of statistical treatises, but rather to indicate the way in which the problem of classification in statistics fits into the larger continuum of inquiry.

More specifically, the need is to see how statistical analysis fits into or extends the general processes of induction-deduction in inquiry. The inductive process consists in establishing general propositions which classify particular instances of fact. These general classifications are defined through the speculative-deductive reasoning which defines the possible relations of characters in the form of hypotheses. This array of hypotheses is gradually narrowed down to the one definition which is most productive in directing generalization—from particular instances through the formation of "singulars" which become, in turn, instances of the general classes.

In simplest terms, there are two requirements of this inductive-deductive process which need to be noted here. (1) The classes used in classifying facts are those established within the inquiry itself. The classes are not "in the facts"; the classes are a part of the purpose and procedure of inquiry. Even though we classify things by their characteristics, the characteristics used are those which have been tentatively established as "meaningful signs" or as "traits" significant for the inquiry. (2) This requirement gives the statistical "classes" the logical status of the generic propositions, with the definitions by which they are distinguished derived from the relevant systems of theory. In economic investigation this is economic

²³ For example, Chaddock R. R., *Principles and Methods of Statistics*. Houghton Mifflin, 1925, Chap. IV, or Yule, G. Udney, *An Introduction to the Theory of Statistics*, Charles Griffin, London, 1929, Part I. The Theory of Attributes.

²⁴ Arthur L. Bowley, *Elements of Statistics*, King & Son, London, 1937.

theory in the broad sense of the term, ideally a system of hypothetical universal propositions.

Economic theory functions in investigations, then, as a general system of definitions which directs the formation of classes. Precisely how this is done is a very subtle and complex affair. It is evident that theory is the method of exploring possibilities. It is also generally agreed that the formation of hypotheses is an essential part of investigation. These hypotheses are tentative "explanations" which are gradually whittled away by investigation to the "best" explanation under the circumstances. Ideally, the contest of hypotheses is a matter of "survival of the fittest" explanation.

It is fairly easy to conceive of an hypothesis as a possible explanation. But in any field of inquiry worthy of professional standing, "ad hoc" hypotheses have a very tentative status. Not until the hypothesis is made an integral part of the general theory can the hypothesis be viewed as genuinely acceptable. This is of course a two-way adjustment; a new hypothesis may have such demonstrable validity that it forces a reconstruction of a large part of previously accepted theory.

As long as the hypothesis is in serious doubt the relevant classification of fact is likewise a matter of question. Consequently both the best hypotheses and prospectively fruitful classifications of fact must be worked out in some sort of pilot studies. Perhaps this relationship can be made explicit by brief attention to the problem of sampling in relation to the formation of classes. All investigators are agreed that some sort of "sampling" is an essential part of social and economic research. However, there is evidently a genuine problem of the relation of the sample to the formation of classes which requires explicit formulation.

The purpose of a representative sample, as it is generally conceived, is to draw out or select sufficient cases so that the "characteristics" of the sample represent adequately the characteristics of the parent universe from which the sample is drawn. The essence of the whole procedure is simply this: how do we go about getting a reliable estimate of the universe from which, in turn, reliable inferences of fact may be drawn—without undertaking to analyze a complete enumeration (even where this is imaginable).

But this procedure would appear to assume that the sampler knows what characteristics are relevant to the inquiry and how they might be classified when found. Unless one assumes that the charac-

teristics themselves are the basis of classification—just in and of themselves, as natural (ontological) classes in the Aristotelian sense—then the drawing of and attempting to analyze a representative sample (in the above defined sense) runs the risk of being both haphazard and expensive. In the determination of relevance, an investigator would almost surely find that he had a vast amount of irrelevant and unusable material in such a “random” sample taken as a first step in inquiry. This would seem to be especially true for social affairs, where each observation combines many interrelated characteristics.

It seems necessary to draw a different kind of a “representative” sample at an earlier stage in the analysis, before the comprehensive representative sample (in the usual sense) is drawn. Possibly enough may be known from previous investigations to make the first sample unnecessary—but the function remains.

What is required from the first sample is that it shall represent, not the *distribution* of characteristics in the universe, but the *full range of possible combinations* of characteristics. The first questions are, how are the characteristics related to each other and of what are they traits? It is conceivable that one single case might embrace the full range of combinations of characteristics—but since this is unlikely the number of instances would have to be drawn from various situations and examined until further examination held the promise of no further new combinations. Nor would this be just a blind affair; the scope of the inquiry itself would suggest the range. Essentially this stage of the inquiry is that of the “case method”—whether the case be a farm, a family, a career of a farmer, a market, a cooperative or a business cycle. The point is that analysis at this stage is concerned with the pattern and significance of characteristics, not the frequency of their occurrence.

This makes a distinction between induction and the determination of frequencies within classes. The inductive process is fundamentally the understanding of how to place a particular case in a general class through the possible reconstitution of a representative singular case as an instance of this general class. In effect then the inductive process is actually completed with the formation of the classes. The frequency with which particulars occur is an additional and independent question.²⁵ It appears that the two steps

²⁵ It was the interest in induction, in the problem of the formation of classes which I take to be the ground of the late Leonard Salter's interest in the “case-

cannot be taken simultaneously. The aim of the "representative" sample in the usual sense of the term seems to me to be directed to the questions of frequencies rather than of induction in the accurate sense of the term.

The logical requirements of classification explain the difficulties of and the increasing concern for the handling of basic economic data—the census and in agriculture, the many collections of data by the crop and livestock reporting service. The general problems here are recognized, of course, by the workers in these various fields; but the explicit attention to them here will indicate the relationships of data classification to the larger continuum of inquiry. We are in this predicament: that the data collected by these various agencies are basic to countless analyses yet the very collection and tabulation of these data must take into account the function of the data in ultimate administration and investigation. It is axiomatic and inherent in the nature of facts, that the questions to be answered by analysis must be implicit in the questions asked of experience (or events) in collecting the data. On logical grounds alone, this makes the collection of data not only an integral part of the research (and administrative) process, but one of the most difficult. On theoretical grounds, we need not only to anticipate the many possible uses in research; these uses need to be so thoroughly comprehended that we know which general facts will be relevant in the various research and administrative contexts. Only the most general facts of the many conceivable "general" situations can be secured by the basic data collection agencies. At one time, no doubt, common sense classifications were sufficient to this need, henceforth it would seem that this field of endeavor requires the most intense efforts in the interpretation of research procedures. In short, the data if genuinely useful, must be classified according to criteria developed in the very processes of inquiry and administration.

The function of statistical analysis in research is essentially that of reducing all explanations other than the one finally accepted to an absurdity. It is through speculation that the possibilities of all sorts, including possible theoretical concepts, are formulated. It is the social task of statistical analysis to eliminate most of these

grouping" method of classification: this *Journal*, Nov. 1942, Vol. 24, No. 4. Also his thesis, "A Critical Review of Research in Land Economics," Univ. Minn. Press, 1948. Salter had an almost passionate disbelief in the method of classification by the simple procedure of "looking for uniformities" in the data. And in this belief he was profoundly wise.

possible explanations without conducting wholesale public experiments to try them out.

This in turn is the ultimate justification of free intellectual inquiry in society; it is through free inquiry that the countless alternatives of society are formulated; it is only through the most hard-headed and systematic analysis that the full range of imaginable alternatives can be narrowed down to a statement of the reasonable alternatives under the existing circumstances.

INPUT-OUTPUT RELATIONSHIPS IN EGG PRODUCTION¹

PETER L. HANSEN

Bureau of Agricultural Economics

Introduction

BECAUSE of their importance in the maximum utilization of feeds and concentrates, relationships between feed inputs and livestock production have been the subject of many research studies. In the case of meat production it was early demonstrated that the input-output function follows that of the principle of diminishing increment.²

Theoretically a similar relationship might be expected in the production of eggs. Less is known, however, about input-output relationships in egg production than in the production of milk, beef and pork. Little information is available regarding the response in egg production obtained from different levels of feeding, although it would appear that experimental work with chickens would be relatively simple as compared with larger animals. This paper attempts to examine available information and to explore this relationship in somewhat greater detail than has previously been done.

The feed consumed by chickens consists almost entirely of grain and high-protein concentrates. It is estimated that of the total livestock consumption of grain and concentrates in the United States, poultry receive more than a fifth, dairy cattle use almost as much, and hogs consume more than a third. The remainder is used for fattening of cattle and for other livestock.³ Of the total grain and concentrates consumed by poultry it is estimated that a little less than three-fourths is used by chickens kept for eggs. This is a substantial quantity and in 1948 it amounted to nearly 16 million tons.

Input-Output Relationships in Livestock Production

The feed-production relationships for livestock at various levels of feeding are known only in their broadest aspects. Experiments conducted in this field by natural scientists in the State Agricultural Experiment Stations and in the United States Department of Agriculture have in most cases been designed to determine the more desirable feeding standards and rations. These experiments have been concerned with the more immediate problem of obtaining increased production, rather than with the less pressing problem of determining the extent to which production varies with different levels of feeding. Only recently has it been recognized that the relationship between feed intake and production for milk is enough different from feeding standards to justify further research.

Several important feed-production relationships should be mentioned briefly in order to indicate more clearly the particular relationship we are concerned about here. One of these feed-production relationships is that found in production of meat from growing animals. The diminishing returns relationship is of economic significance here because the relative prices of feed and meat animals of various grades determine the point on the curve to which it pays to feed.

Feeding standards such as those recommended for use in feeding milk cows and laying hens are ratios of feed to production. The higher the production the larger is the quantity fed. Because of variation in capacity, different cows and laying hens consume different quantities of feed when fed to produce maximum output. Such data are sometimes erroneously used to construct input-output relationships, although the variation found in feed intake is a result simply of differences in inherent capacity to produce.

Another type of feed-production relationship is that obtained by feeding animals of the same inherent productivity at different levels in order to determine the input-output relationship. This is the type of relationship which needs to be investigated in production of eggs. In the production of milk this relationship was determined in a special research project undertaken by the United States Department of Agriculture in cooperation with 10 State agricultural experiment stations. A report was issued in 1942.⁴ It was

⁴ Jensen, Einar, Klein, John W., Rauchenstein, Emil, Woodward, T. E. and Smith, R. H., "Input-Output Relationships in Milk Production," U.S.D.A. Tech. Bul. No. 815, May 1942.

found that as production of milk is increased by heavier feeding there is a smaller increase in output for each additional unit of feed used than feeding standards would have indicated. The law of diminishing physical increments was also found to apply.

Input-Output Relationships in Egg Production

Many feeding experiments with chickens have been conducted for the purpose of determining what the effect would be on egg production or on the health of the chickens, if one or more of the necessary nutrients were increased or eliminated or fed in quantities considered inadequate to provide normal requirements. This specialized type of input-output feeding experiment is extremely useful in testing the economic importance and need for different nutrients, but it has limited value for an economic appraisal of general input-output relationships for different levels of feeding. Another type of data on feed consumption and egg production is that available from egg laying contests. In these contests the birds are fed all they will eat of a balanced ration in order to determine the productive capacity of different strains of layers. The relationships of feed to production of eggs obtained in these contests are like those obtained for milk cows in establishing milk or butterfat records. Such data would be expected to show a straight line relationship between feed intake and production in the absence of any reason for assuming that higher capacity birds would make more or less efficient use of the production ration.⁵

In a study in Utah an attempt was made by Wells and Clawson to use data as to feed consumption and egg production from farm flocks to measure the feed-production relationships.⁶ The data were obtained from commercial egg-producing Leghorn flocks and, so far as could be judged at the time the average productive efficiencies and capacities of the various flocks were thought to be approximately equal. The data came from well-managed flocks in which the layers apparently were fed as much as they would eat. However, they were probably not fed equally well-balanced rations. The variation in the relationship between feed intake and production may therefore have been chiefly a result of variations from farm to farm in numerous factors. At any rate, as there is no assur-

⁵ Brody, S., Funk, E. M. and Kempster, H. L., "Growth and Development." Mo. Agr. Expt. Sta. Research Bul. 278, p. 46.

⁶ Wells, O. V. and Clawson, Marion, "A Study of Egg Production per Hen in Central Utah" This Journal, Vol. XV, October 1933, p. 633.

ance of the real differences in the levels at which the layers were fed these data are suitable only for a rough approximation of the relationship of feed to production of eggs under farm conditions. The data are similar in some respects to those obtained in egg-laying contests, except that in laying contests the greater degree of control makes it more certain that a measure of the capacity of the birds to produce eggs has been obtained.⁷ Neither the data from egg-laying contests nor those from farm records or surveys appear to lend themselves to an analysis of the nature of the feed-egg input-output relationship. The study presented by Wells and Clawson did not reach a conclusion in this respect, although a recent textbook using this study as a basis implies that a diminishing returns relationship may exist.⁸

The most revealing study available appears to be one undertaken by the United States Department of Agriculture at the Southwest Poultry Experiment Station, Glendale, Arizona, in 1936 and 1937.⁹ This experiment was set up for the purpose of determining the effect of limited feeding on egg production rather than to measure the effect of additional feeding. This appears to approach the problem in an inverted fashion and may have influenced the results for our present purpose, as the rations were adjusted primarily to fit the full-feeding level. Nevertheless, this controlled experiment is very suggestive.

The experiment at Glendale consisted of two parts, each covering a period of a year. One part of the experiment began December 24, 1935, and ended December 23, 1936. Another part of the experiment began January 8, 1936, and ended January 6, 1937. The White Leghorn pullets used were divided into groups of 25 each. All were the same strain and as nearly as possible the same weight. In the first part of the experiment three groups of 25 birds each were fed different quantities of an all-mash ration. The first group in this lot was given free access (*ad libitum*) to the diet and thus got all they would eat. A second group was given only 87.5 percent of that eaten by the first group the previous day and a third group only 75 percent of that quantity. This was repeated with another

⁹ Heywang, Burt W. "The Effect of Restricted Feed Intake on Egg Weight, Egg Production and Body Weight." *Poultry Science*, Jan. 1940, Vol. XIX, No. 1, p. 29.

lot of three groups averaging somewhat less in weight. The results of the first lot of three groups are shown under a, and that of the next lot of three groups under b in the chart (Fig. 1).

In the second part of the experiment eight groups of pullets were used. Three of these groups were used to repeat the experiment explained above, and the results are shown under c in the chart.¹⁰

A summary of the experiment is presented in Table 1. This shows that a reduction of 12.5 percent in the feed intake cut egg production to 68.2 percent of that obtained when the layers were fed all they would eat. When there was a reduction of 25 percent in the feed intake, production of eggs dropped to 47.5 percent of that for the full-fed level. The relationship found may also be expressed by saying that production of eggs dropped a little more than twice as much as the reduction made in the rate of feeding.

TABLE 1. EFFECT OF REDUCED FEED INTAKE ON EGG PRODUCTION

Level of feeding ^a	Percentage of level 1		Eggs produced		
	Rate of feeding	Eggs per layer ^b	Lot a	Lot b	Lot c
	<i>Percent</i>	<i>Percent</i>	<i>Number</i>	<i>Number</i>	<i>Number</i>
1	100	100	193	146	171
2	87.5	68.2	127	101	120
3	75.0	47.5	90	67	85

^a All groups under level 1 were given all they would eat.

^b Averages of the three groups fed at the same level.

As shown in Figure 1 by the similarity of the three curves, the results are nearly identical. Differences in the level of production among the three experiments (lots) were apparently caused by the difference in weight of the layers used. The layers in the three groups in lot b averaged considerably smaller than those in the six groups in the other 2 lots.

¹⁰ The other five groups of pullets were fed different quantities of the diet for a part of the period. Approximately half way through the experiment the quantities were changed in order to observe whether this would result in a change in egg production, egg weight, and body weight of layers. Production changed in accordance with feed intake, egg weight remained nearly constant, and average body weight was not significantly affected by restricted feed intake. The most important finding in this part of the experiment is perhaps summed up in the observation that the egg production of layers apparently can be increased again to approximately the full quantity permitted by their capacity when the amount of feed intake is increased even though the feed intake has been as low as 75 percent of what they might have eaten *ad libitum*. This is quite different from the situation with milk cows where the milk flow once reduced during the lactation period can only rarely be brought up appreciably during that lactation period.

The results indicate a slightly increasing returns relationship as the layers were fed more nearly the full quantity they would eat. The feed-production relationship from the farm survey in Utah is plotted in Figure 1 in order that the slope for these data may be compared with that of the input-output data from Glendale. The relationships between feed and egg production from the Maryland

FIG. 1.—The feed-egg relationships from Glendale are based on various levels of feeding for strains of the same productive capacity. Data from egg laying contests and estimated feed requirements from NRC show the feed consumed by layers of various capacities. The Utah survey data probably hold an intermediate position, measuring partly capacities and partly differences in ration and management from farm to farm.

egg-laying contests and from feed requirements published by the National Research Council are shown. There is a surprising similarity in the slope of relationships obtained at Glendale and those shown for the egg-laying contests and the feed requirements where-

as the relationship obtained from the farm survey data is quite different. The marginal efficiency of production on the farms in Utah seems quite low as it takes about 40 pounds of additional feed to increase average production by 50 eggs. A comparison of the data from Glendale with the approximate feed requirements estimated by the National Research Council¹¹ as represented by the straight lines in the chart indicates that the layers used in the Glendale experiment were relatively efficient producers. This may be due in part to better than average climatic conditions at Glendale, Arizona. Another explanation is that the estimated feed requirements represent average values for both light and heavy breeds and are sufficiently high so that an adequate quantity of nutrients is assured even under unfavorable conditions.

A generous ration is not utilized as efficiently as a less adequate ration. Morrison, for example, states that "a liberal ration is not digested and utilized quite so completely as a scanty ration. For this reason . . . a cow in milk which is fed with the liberality necessary to produce a good yield of milk undoubtedly needs more feed for mere body maintenance than she would if she were fed a scanty ration that would be sufficient to maintain her weight when dry."¹²

According to the results obtained, the strains of White Leghorns used in the Glendale experiment were highly efficient. The groups fed ad libitum (all they would eat) were consuming slightly less than estimated requirements but the groups fed only 87.5 and 75 percent as much were getting considerably less feed than ordinarily would be required by layers of similar weight and production. In the groups which were fed at these reduced rates it must be assumed that the feed was very efficiently utilized. The net result was uneconomical, however, because of the large decrease in production of eggs although the average weight of the layers remained fairly constant.

Conclusions Which May Be Drawn from the Glendale Data

The most significant conclusion which may be drawn from the Glendale experiment is that there is nothing within the range of the data to indicate a decreasing return for additional units of input.

¹¹ Cravens, W. W., Almquist, H. J., Norris, L. C., Bethke, R. M., Titus, H. W. *Recommended Nutrient Allowances for Poultry*, A Report of the Committee on Animal Nutrition, National Research Council, Washington, D.C., 1944.

¹² Morrison, F. B., *Feeds and Feeding*, p. 76, Ithaca, New York, 1937.

On the contrary the results seem rather to imply a slightly increasing return relationship.

Two possible explanations appear for the apparent tendency toward increasing returns. The first lies in the nature of the experiment itself, in which the feed intake was reduced by exact percentages from ad libitum feeding. The feed mixture which originally was well balanced for the needs of the layers at full capacity became less well balanced. In other words, when the total feed intake was reduced 12.5 and 25 percent some nutritional factors may have been in greater relative scarcity than others. If this were the case it might explain the increasing returns slope of the curve.

From a theoretical standpoint it would be extremely interesting to learn whether the input-output relationship in egg production reaches a point at which a diminishing output is obtained for each additional unit of input. In the Glendale experiment, for example, it is possible that the use of several more groups of pullets fed, say, 2.5 percent less than the "ad libitum" group and another fed five percent less, a third 7.5 percent less and so forth, might have indicated a point at which production would have increased at a declining rate. Insofar as can be seen it would appear that this point in any case is so near the point of maximum feed intake and production that it probably would not be of practical significance to poultry farmers.

The second possibility is that the capacity of these layers to utilize feed for production of eggs was relatively low. In fact, so low that even at the upper levels of production the relationship between input and output still did not reach into what might be called the economic range. That is consumption of feed did not reach the point on a theoretical curve at which diminishing increments begin.

This hypothesis is mentioned because of its possible application, if true, to future breeding work. If production of eggs as indicated by Brody, et al. may be limited by the capacity of the metabolic system of the layers, future progress in breeding for greater capacity might some day push the input-output relationship into an area of diminishing returns.¹³ Meanwhile, the data from the Glendale experiment seem to indicate that the input-output relationship

¹³ Brody, Samuel, Funk, E. M. and Kempster, H. L., *Growth and Development* Mo. Agr. Expt. Sta. Research Bul. 273, p. 30, March 1938.

is not that of diminishing returns up to the point of maximum capacity of the layers used.

Economic Application—Practical Use

In appraising the conclusions from the Glendale experiment one must be careful to distinguish between the findings of the study as applied to conditions such as those set up in the experiment and the wider application to poultry feeding under other conditions. As in the case of any experimental study, the application of results to a wider area is a problem in sampling and inference.

In this case, it is clear from the experimental results that for the conditions studied, feeding the layers all they would take of a well-balanced ration was most profitable. For the three levels studied there was no indication of diminishing marginal returns. Other evidence of a less direct and conclusive nature, also seems to be in agreement. We can say therefore that within the usual range of feeding experience, it is probable that layers fed to capacity will either show no diminishing marginal return increments or if they should, it would be so little as to be of minor consequence.

At the same time it should be pointed out that the experiment was restricted to three levels, that it covered only one strain of Leghorns in one location, and that the ration for each of the three levels was not adjusted in composition. It might well be that changes in those factors or others would result in the appearance of some diminishing marginal relationships. In fact it seems almost certain that in the nature of things, some diminishing marginal relationships would appear in connection with some of these possibilities.

However, let us assume for the moment, that the essentially straight line relationship found is generally applicable and consider what it would mean. First of all, it strongly reinforces the recommendation that has been stressed by poultry extension workers that hens should be fed to their full capacity of a well-balanced ration. For flocks fed for commercial egg production it means that adjustments in feeding to meet changes in economic conditions should be made by adjusting numbers of layers (culling), rather than by changing feeding rates. In this respect feeding for egg production appears to differ from feeding in other types of livestock production. The input-output relationship in feeding milk cows, for example, is definitely one of decreasing increments, so

that adjusting the quantity of feed per cow is one of the most important means of adjusting to changes in milk-feed price relationships. Again in feeding hogs, beef cattle, and poultry for meat production, the diminishing marginal gains from additional feeding of concentrates are so important as to play a very important role in working out the most economic feeding rate. Not so in egg production within the usual ranges of feeding adjustment.

In some respects this means that the egg producer has a simpler feeding problem than producers of other livestock products. The chief problem is that of getting the layers to eat as much as their capacity permits. The work of Brody and his co-workers, referred to earlier, suggests that laying capacity is limited by the hen's ability to assimilate feed. The fundamental reason for the higher relative maintenance ration for the hen as compared with the milk cow lies in this situation. Improved breeding has been effective by increasing the hen's ability to handle more feed and convert it into eggs. Apparently higher rates of egg production have not been associated with any decrease in marginal efficiency in feed conversion.

The above reasoning suggests also that there may be room for further progress in increasing egg production per bird if means can be found for stepping up the hen's physiological capacity. This may become possible either through breeding, feeding, or some combination with management.

Work with amino acids, and other nutritional factors indicates that the way is still open. Both the feed-egg relationship found in the Glendale experiment and the high percentage of feed used for maintenance in the case of the hen means that as production increases, the average output per unit of feed increases more rapidly than is the case with many other types of livestock production.

The Glendale experiment, although suggestive, is limited in application. This type of work needs to be expanded to cover additional situations and conditions. Additional work on input-output relationships in egg production might well be done as a joint poultry-husbandry and farm-management project perhaps in cooperation with several state agricultural experiment stations, following the pattern used in the input-output study in milk production.¹⁴ The project should include use of other breeds and strains of chickens and different rations fed at a greater number of different levels of feed intake than were used at Glendale, Arizona.

¹⁴ Jensen and associates, *op. cit.*

THE STATUS AND POSSIBILITIES OF RURAL PRODUCING COOPERATIVES

WERNER Z. HIRSCH*
University of California

M. R. T. V. EMCLIANOFF at the end of his book, *Economic Theory of Cooperation*,¹ concludes that: "‘Productive’ cooperative associations . . . always (have) been a favorite type, supported by public opinion, by its socio-reformistic enthusiasts, by governments in various states, and by special subsidies, public and private. Despite this, and notwithstanding never-ceasing attempts to promote and organize such associations, they have not demonstrated any viability and still remain a lifeless theoretical scheme without any chance of realization in a surveyable future."

In spite of this categorical statement a reconsideration of the status of producing cooperatives in general and rural producing cooperatives in particular appears to be warranted, if only for two reasons. First, and this aspect appears to be of primary interest at this particular time, it may be well to consider whether and to what extent rural producing cooperatives can play a role in the implementation of President Truman's bold New Program, point four of his 1949 Inaugural Address. Second, the Russian and Israeli experiment with regard to rural producing cooperatives on a large scale, as well as the numerous machinery pools in various countries, including the United States, furnish interesting material for analysis. To study the possibilities and implications of using rural producing cooperatives as an instrument in the development of economically less fortunate and little developed countries, is a major concern of this paper.

Concepts and Characteristics

In order to describe properly some of the main characteristics of rural producing cooperatives, it may be well to indicate first the position occupied by them in relation to other types of cooperative efforts. From an over-all view it is quite convenient to group cooperatives into three major groups according to function.

(1) Purchasing cooperatives, formed by people who pool their

* The writer acknowledges indebtedness to Professors M. R. Benedict and J. B. Condliffe for important suggestions.

¹ Ann Arbor, Michigan, Edwards Brothers, Inc., 1942, pp. 253-254.

needs for goods and services which they purchase jointly. Their primary objective is to purchase more economically or, as it is often called in more technical terms, to maximize their members' satisfaction.

- (2) Marketing cooperatives, formed by producers who pool for joint sale their products which they produce individually. Their primary objective is to assist their members in maximizing their profits.
- (3) Producing cooperatives, formed by producers who pool their labor and/or machinery in order to produce goods and services jointly. Their primary objective is to assist their members in maximizing their profits.

The three major types of cooperation have been presented in this succession for an important reason. The three types follow each other in an order which corresponds to the decrease in the number of fields in which the individual is free to make his own decisions, independent of group decisions. For example, purchasing cooperatives may be considered as a type of cooperation which least curtails private decisions. From this point of view one may say that purchasing cooperatives are the lowest type of cooperation. Almost no purchasing cooperatives require members to patronize exclusively the cooperative store or services. All other facets of the individual member's life are also left untouched.

Not so in the other two types of cooperation. Members of marketing cooperatives often sign agreements to market all of one product (with the exception of that for home use) through the cooperative. It is also common to find members of agricultural marketing cooperatives belonging to related purchasing cooperatives at the same time. In some cases, for instance the California Fruit Growers Exchange, the marketing cooperative also fulfills the functions of a cooperative purchasing agent of fertilizer, packing material, etc. It immediately becomes clear, that membership in a marketing cooperative is likely to curtail a person's private decisions to a larger extent than membership in a purchasing cooperative. Members of producing cooperatives, with the exception of machinery pools, relegate even more of their individual decisions to the cooperative. All producing cooperatives which pool their members' labor simultaneously fulfill also cooperative purchasing and cooperative marketing functions.

Producing cooperatives may be further grouped according to

whether they operate in rural communities or industrial cities. This paper will be concerned with rural producing cooperatives. These may be subdivided into three major types:

- (1) *Rural machinery pools*: It is one of the interesting phenomena of our age that people living in capitalistic, socialistic and communistic countries all pool certain efforts and equipment. The reason is simple. The furnishing of certain goods and services on an individual basis poses problems which are practically insurmountable. People have become accustomed to having national security, police and fire protection, postal services, etc., furnished not on an individualistic private basis, but by public pools. In the same way, all the world over mechanization has apparently induced small holders to pool heavy agricultural machinery, such as tractors, plows, mechanical spraying machines, harvesters, threshers, pumps, etc. It is because of the fact that the small farmer seldom can finance and effectively use large mechanized equipment that rural machinery pools are gaining in importance. In the United States, for instance, a considerable part of rural electrification is carried out on a cooperative basis. Farmers cooperate and with the aid of government loans pool resources to purchase and jointly operate equipment which furnishes their farms with electric power, a service which obviously cannot be economically supplied by each farmer separately.
- (2) *Collective farms with commercial enterprises operated cooperatively*: Since the start of the twentieth century, collective farms in which all commercial enterprises are operated jointly have been on the increase in many countries. Russia, Poland, Bulgaria, India, and Israel are a few of the countries which are experimenting on a rather large scale with this type of rural cooperation. Under such a setup relatively large tracts of land are jointly operated by member-farmers, who have their private individual dwellings and small gardens. On these small plots each family can produce its own fruits and vegetables and can even support some livestock to meet the family's needs for dairy products, eggs and meat. Such collective farms are usually managed by a committee of management elected by the farm's members. At regular intervals the total net returns of the farm are distributed among

its members according to formulae which are based on members' input and participation.

- (3) *Collective farms with all property being pooled and operated cooperatively:* In a very few countries, for instance Israel, a considerable segment of the agricultural sector is composed of collective farms in which members pool all their property. All land, shops, livestock and dwellings are cooperatively operated and, for all practical purposes, no private property exists. No wages are paid, but all individual needs are met by the common treasury. All members are equally compensated. Here, as in type (2), a committee of management, elected by the members, decide the farm's organization, its products, each member's work, etc. This type of rural producing cooperative, indubitably, curtails privacy and individual decision much more than either of the preceding types.

In summary it may be stated that among the various types of rural producing cooperatives, machinery pools curtail individual decisions least and, therefore, their successful operation poses fewer problems than the others. Collective farms in which all property is pooled and jointly operated is the other extreme. Here, group interest and decision almost completely supersedes individual interest and decision. In countries in which for generations people have been accustomed to live their private lives and to make their individual decisions, cooperative efforts inherently generate centrifugal forces which are apt to disrupt cooperation. The more extensive the people's individualistic tradition and the more the individual's interest diverges from that of the cooperative, the stronger will be such disruptive forces. There exist apparently two major forces which can counteract such centrifugal forces. For one, compulsory cooperation offers the dissatisfied members little room for the expression of their feelings and inclinations. On the other hand, common background, beliefs, ideals and outside pressure constitute forces which have proved capable of perpetuating voluntary cooperative efforts for generations. The Mormons and the Israelis furnish good examples of the latter case, while the collectivization by decree in Russia is a good example of the first. Both forces have their limitations. Compulsory collectivization is not consistent with freedom of choice, while, as the outside world changes, common beliefs, ideals and external opposition may dwindle away or lose their comparative importance. It is this latter fact which appar-

ently hit hardest cooperation among the Mormons in the United States.

After these initial general remarks it may be well to consider from close by some of the more important rural producing cooperative efforts of this century. Among the large-scale efforts, the Russian and the Israeli are certainly the most outstanding and therefore warrant some analysis.

The Russian Experiment

After the Russian revolution in 1917 apparently no effective programs for the redistribution of land were implemented in spite of previous discussions. Instead, land-hungry peasants seized and redistributed the land which earlier had been held by large land-owners. As a result the land became more and more subdivided and the State was left with relatively small farming units. At the same time the need for greater agricultural output became more and more urgent. To meet these needs by modernizing and mechanizing agriculture and to tie the farm sector closer to the industrial sector, the planners of the first five year plan (1928-1932) decided to collectivize agriculture. While in 1929 only about four percent of all farms in Russia were rural producing cooperatives, by 1938 they had grown to 94 percent.²

The collectivization of Russian agriculture was carried out under government sponsorship and supervision. It was not a voluntary movement. According to government decrees, rural producing cooperatives, i.e., Kolkhozes, were established. Kolkhozes are a variation of rural producing cooperatives, discussed as type (2). The land of a Kolkhoze belongs to the State, and all commercial enterprises are operated cooperatively while members live in individual dwellings surrounded by small plots of land for individual use. In order to stimulate production by mechanizing agriculture, Kolkhozes are furnished with mechanical equipment by government-owned and -run Machinery and Tractor Stations, which are found all over Russia. Machinery and Tractor Stations receive their equipment directly from the State and make it available, at fixed charges together with expert advice, to the Kolkhozes. It seems that the Machinery and Tractor Stations constitute a major link between the State and each Kolkhoze. Through these stations the State on

² Rabinowitch, Germina, "The Kolkhozes in the U.S.S.R." *Rural Sociology*, Vol. 8, No. 3, Sept. 1943, p. 256.

the one hand furnishes technical advice and instruction, and on the other controls agricultural production of the entire country.

Under this setup the interest of the individual and the group often clashed. Compulsion, usually favoring the group interest, counteracted all centrifugal forces which otherwise might have disrupted the cooperative effort. Thus, when by 1939 the members of many a Kolkhoze had been putting more and more emphasis on their small individual holdings (which were attached to each house), showing strongly individualistic tendencies, the State interfered. In May 1939 the Central Committee of the Communist Party and the Council of People's Commissars of the Soviet Union issued an order which was aimed at protecting land belonging to the collective farms against attempts at individual appropriation on the part of farm members or against attempts to extend individual holdings beyond their original limits.³ In September 1946 another order titled "Measures of Liquidating the Violations of the Charter of the Agricultural Artel in Kolkhoze" was issued.⁴

It should be realized, however, that in spite of all negative aspects of this system, the rural producing cooperatives together with the Machinery and Tractor Stations furnished an excellent instrument through which mass education, training and mechanization could be implemented very rapidly and on a very large scale. In this sense, this system offered a convenient vehicle for the development and improvement of Russian agriculture.

The Israeli Experiment

While the collectivization of farms in Russia was compulsory the movement of rural producing cooperation in Israel was a wholly voluntary, grass-root movement. The Jewish settlers who entered Israel early in the twentieth century had little, if any, farming experience. Living and farming conditions in the new homeland were most challenging, due to the adverse climate, strange and often hostile environment, lack of funds and experience. At the same time, these settlers had been shaken in their belief in the old European system of individualism, and were imbued with an idealistic desire to create a new social order. This ideal was to take the form of large-scale cooperation, a form which helped

³ Rabinowitch, *op cit*, p. 259.

⁴ Jasny, Naum, "The Plight of the Collective Farms," this Journal, Vol. 30, No. 2, May 1948, p. 305.

solve many of their problems such as lack of funds, experience, changed environment, prevalence of disease, etc.

In 1908 the first Kvutzah, a rural producing cooperative of type (3) was established at Daganiah. Since then their number has been increasing steadily. In 1938 about 30 percent of all Jewish villages in Israel were Kvutzoth (plural of Kvutzah) and by 1942 the percentage had increased to about 36 percent. There are two major types of Kvutzoth. One type has an average membership of about 100-200 members while the second, usually referred to as Kibbuz, has a membership of up to 1,000 members. The reason for this difference is primarily a philosophical one. Those who favor the small unit maintain that a cooperative is only an enlarged family consisting of people with common interests and social, cultural and human ties. Those, however, who favor the larger unit maintain that such an environment offers the individual more chances to develop and to associate himself with people who share his social, cultural and human interests.

Each Kvutzah is governed by the general meeting of its members, which elects a committee of management to execute administrative duties. A secretary-treasurer handles the cooperative's finances, a work-organizer assigns each member to his respective job and a Mukhtar handles the cooperative's external relations. Standing committees assist the committee of management.

Thirteen years after the first Kvutzah had been established another type of rural producing cooperative made its appearance. Many settlers who were eager to cultivate the homeland were not willing to give up so much of their individualism. In 1921 the first Moshav-Ovdim was established at Nahalal. A Moshav-Ovdim is a village consisting of individual farms. Each farmer in the village decides what and how much to plant, but big farm machinery, cold storage houses, etc., are purchased and operated on a pool basis. Almost all members belong to the same marketing cooperative as well as purchasing cooperative.

In the late 1930's yet another system of rural producing cooperative was started. In many respects it is a compromise between a Kvutzah and a Moshav-Ovdim. Settlers became more and more aware of benefits which result from large-scale farming as well as from a certain degree of individualism. The Meshek-Meshutaf, a rural producing cooperative of type (2), resembles in many respects the Russian Kolkhoze, with the exception that it is entirely volun-

tary. All commercial enterprises are jointly operated, while each family lives in its own dwellings and cultivates its own small garden. At the end of the year the cooperative's net returns are divided among its members. The remuneration is according to the respective contribution of each member.

There can be little doubt that rural producing cooperatives have been one of the most important factors in the development of Israeli agriculture and to a certain extent of the entire economy. The continuation and perpetuation of rural producing cooperation in the Kvutsoth form is faced by most severe dangers. This type of cooperation minimizes private decision and therewith generates a maximum of centrifugal forces. Once the conditions of the State of Israel and its people have improved sufficiently and the pioneer atmosphere has dissipated, many of the centripetal forces will have disappeared. Life in New England in the early colonial period furnishes an interesting parallel. Adverse conditions exemplified by Indian attacks led to close cooperation between the early pioneers. Once conditions improved, many joint efforts disappeared. The odds are that, without government interference, future types of rural producing cooperatives which leave more room for individualistic tendencies will gain in importance.

Rural Producing Cooperatives and the Development of Economically Underdeveloped Countries

There are strong indications that a sincere effort to better the plight of economically less fortunate people is in the making. It is a fact that almost all of these economically underdeveloped countries are predominantly rural in nature.⁵ As a matter of fact, it is partly because of pronounced rural character that these countries are in many respects backward and have such relatively low standards of living. It is obvious, therefore, that if the standard of living of the people of these underdeveloped countries is going to be raised, an initial major effort has to be made within and by their rural sectors.

In general it appears to be true that in the rural sectors of most economically underdeveloped countries the level of living is relatively low, because output per man-hour is low, technical know-how and training very limited and pressure on the land consider-

⁵ It is estimated that, for instance, at present about 75 percent of China's, 70 percent of India's and 78 percent of Korea's population is engaged in agriculture.

able. The question is whether and how much rural producing co-operation planned to conform to the people's education and tradition can help to improve this state of affairs. It is well to inquire whether and to what extent rural producing cooperatives can contribute by facilitating the gradual mechanization and improvement of agricultural practices, the spread of technical know-how, and the healthy development of small-scale rural industries.

Low productivity of farm labor together with a generally unsatisfactory state of farming in many economically underdeveloped countries is related to the small size of farming units. Land-wasting and work-impeding stone walls or hedges, which so often encircle these small holdings, further complicate the problem. If joint cultivation of certain lands would be accepted, stone walls could be removed and plowing of larger areas of land possible. Gradually larger and more modern equipment could be introduced which in many cases could lead to more productive and desirable cultural practices and, possibly, higher total output. The cooperative would often be able to borrow and pool capital, in order to finance such improved practices, which to individual small holders would prove to be inaccessible. In this connection one should recognize that even in the United States cooperative purchase of heavy farm machinery has been common among farmers for many decades.

One factor, among others, which makes the problem of education and vocational training so difficult in most Far Eastern countries, is the multitude of farms. Under such conditions it is hard for authorities to reach any large number of farmers. Also, farmers who are living on such small land holdings as to be always close to starvation, can hardly afford to try out and introduce better cultural methods. They are often afraid to deviate from the traditional practice, because crop failure may prove to be ruinous and fatal. Once, however, groups of farmers, and in particular producing cooperatives, are found all over the land, the authorities' physical problem of reaching their rural population has greatly diminished. Each cooperative can assist in diffusing information, education and vocational training to the members and see to their judicious application. Because of the fact that all rural producing cooperatives have certain common features, they offer a convenient framework for the general spreading of know-how.

Rural production cooperatives need not necessarily be exclusively agricultural. Many Israeli Kvutsoth not only maintain

shops designed to build and repair certain agricultural equipment houses and tools, but also manufacture certain nonagricultural articles for sale. Rural communities can produce parts of their own nonagricultural needs, while certain amounts of various products can be offered for sale. Products do not necessarily have to be in the nature of end-products, but they may be components of agricultural implements, textile accessories and parts of machine tools which are assembled at factories for further manufacture. The development of small-scale industries by rural cooperatives, besides complementing agricultural efforts, has two very important facets. Almost all economically underdeveloped countries lack capital and capital goods as well as possibilities to acquire them on a large scale in the near future. Here, in the process of initial development rural small-scale industries would come in very handy. Also, such a setup could absorb a considerable part of the population which at present is either not very productively employed or which may no longer be needed in agriculture once cooperation is introduced.

It seems, therefore, that rural producing cooperatives can fulfill an important part in the economic development of underdeveloped countries. Mahatma Gandhi and his followers go even further, hoping that rural producing cooperation will assist in the raising of people's standard of life as distinguished from raising their standard of living.⁶ This, however, is outside the scope of this paper. Instead, some of the problems which are related to the introduction and expansion of rural producing cooperatives in economically underdeveloped countries will be considered.

It should be realized that not all countries, if they use cooperative producing methods at all, will and should use the same method. Education and traditions will and should be one of the major factors which determine the type of rural producing cooperative. Farmers like the American farmers, for example, who are accustomed to individual farming can hardly be induced voluntarily to join collective farms. Still the same farmers may be willing to join various machinery pools. At the same time, it might be expected that the village farming which existed in India prior to the British Administration would furnish an important precedent and tradition on which relatively widespread rural producing cooperation could be built.

⁶ In Gandhi's vocabulary "standard of life" relates to the human and social side of life while "standard of living" relates to the material side.

With respect to the speed with which rural producing cooperation can be introduced and expanded there will in general be a difference as to whether the cooperative effort is voluntary or compulsory. Voluntary cooperation historically always has been a relatively slow process. Whatever the conditions would be under which the various economically underdeveloped countries would introduce and broaden cooperation, they would be badly handicapped by lack of local leaders and managers, who could successfully head cooperatives. If nothing else, paucity in number of trained personnel who would be able to organize and head cooperatives will considerably slow down potential rural cooperation in these countries. Recognizing this fact these countries should make an all out effort to train leaders and personnel.

In conclusion it may be stated that at present in many countries rural producing cooperatives exist. In certain countries they constitute important parts of the agricultural sector. As the world gains in cooperative experience and it becomes increasingly clear that certain facets of rural producing cooperation may constitute convenient tools in the development of underdeveloped countries, cooperative rural producing efforts may very well gain in importance. Rural producing cooperatives can facilitate gradual mechanization and improvement of agricultural practices, spreading of technical know-how and rural small-scale industrialization. It is for this reason that India and China very likely will soon furnish a large-scale testing ground for various types of rural producing cooperatives. Some Near Eastern countries with the Israeli experiment before them are beginning to think of launching their own experiments in this field. There seems to be no reason why, with proper guidance, the benefits of rural producing cooperatives cannot be reaped under various types of government.

NOTES

SOME RULES FOR MAKING ECONOMIC STUDIES IN A POLITICAL ENVIRONMENT

1. Be sure the sponsoring agency is square and wants an honest job done.
2. Get a clear concise assignment.
3. Stick to your study.
4. Don't play politics yourself.
5. Stay out of the newspapers.
6. Let your job speak for itself.
7. Report only to your own chairman. Let him take the bows—and the brickbats.
8. Be sure you have a reasonable amount of emotional stability, otherwise you will be quite unhappy.
9. Don't try to answer political attacks.
10. Be fair with the people you are studying. Give them a fair, complete hearing. Be sure you understand them. Accept no favors but don't be stand-offish and holy. Have a clear understanding with top management. If you play it square, they will respect you even if they don't agree. Keep your mouth shut. Don't gossip. If a company can influence you, they will not respect you and will be slow to take you into confidence.
11. Report *all* the facts. Don't color them or emphasize them to support your own or any one else's prejudices.

E. C. YOUNG

Purdue University

A COMMENT ON "PLANNING AND CONTROL"*

PLANNING AND CONTROL, admitted to the field of respectable economics very reluctantly and only because of war and depression emergency, I submit are now with us to stay. They are here not as stepchildren or temporary expedients. They have so completely pervaded our system that only those on the most stubborn fringes of intellectual life continue to rant that the "norm" is the automatic system of classical economics and that all these interferences are merely temporary and unholy aberrations from the "norm." I refer, of course, to the National Association of Manu-

* This note is a digest of extemporaneous remarks made at Laramie, Wyo., August 19, 1949.

facturers and the instructors in nine-tenths of all courses in elementary economic principles. The prevailing attitude at the meeting of the American Farm Economics Association at Laramie was in striking contrast, in this regard, to that of the three-day Forum of Labor, Agriculture and Industry held there immediately preceding. Throughout that "Forum," heavily weighted on the side of what I shall call, in polite understatement, "conservatism," was an undercurrent of dreadful fear regarding "planning and control" of economic activity. At the AFEA meeting they were accepted as necessities; the most conservative statements heard being but requests that controls be kept to a minimum and that bureaucracy please quit acting so almighty and be a little more responsive to the decent and respectable local-powers-that-be. Farm economists have apparently become the leading iconoclasts of this day, albeit with great reluctance—with reluctance because it scares anyone to find his precious little stock of absolute truths melting away.

Are we ready for an age when humans will determine their own destiny and so-called natural laws will be repealed one after the other? Obviously not, as we were not ready for the atom bomb or as society is never ready for what remorseless technological progress forces upon it. Yet, we must succeed. I quote from Mr. Harold Rowe's paper:¹

"My own interest in this whole subject is rooted partly in a belief that study of the war experience can yield results applicable to conditions of peace as well as to those of war. In a way, it reflects a suspicion that the economic conditions of a military emergency are not so basically different from those that may develop in other situations, and hence are not so exceptional as is oftentimes supposed. Greatly expanded government intervention in the operation of the branch of the economy which receives primary attention in the work of the majority of us here has been based upon more or less continuous recognition of some degree of cyclical or war emergency throughout most of our experience."

I submit that the United States is henceforth arrived at a point where the need for planning and control is accepted as a datum. The world other than the new world has been in such state for some time, but the new world has not, because of its great good fortune in location, physical resources, and youth. I quote again from Mr. Rowe:

¹ Presented at Laramie and to be incorporated in a forthcoming Brookings Foundation publication.

"If, to use a classification sometimes employed by military experts, instead of comfortable war such as the last, we were to experience an austere war, this compulsion toward planning would be greater. Conditions in a real war for survival would call for complete planning."

Many of us believe that the world as we prefer it, is now at war for survival against the world as we do not prefer it. I shall omit entirely discussing the question of "why" or "whose fault."

But our foundations have fallen away. We find in the haphazard control experiences of the war that if the so-called automatic allocation of goods in the market according to demand expressed in money is no longer available to us, we are lost. There may be other allocation measures conceivable to man. Measures of necessity, technological and psychological, can perhaps some day be discovered and charted on a grand combination of thermocouples, ammeters, and "electrocraniographs," but we do not have them today. About all we have so far are public opinion polls and a growing body of social investigation and research, various segments of which we represent.

We practitioners of the art of economics stand before the economic facts of life in 1949 pretty naked. It is my humble opinion that an admission of that would do us a lot of good and perhaps open our minds to some possible answers which cannot now penetrate through the rank growth of dogma that heretofore has had possession.

As an exercise in rejecting dogma I refer to a portion of Mr. M. K. Bennett's paper² where he says:

"The producers are to become stepchildren even more than before—residual claimants to what they produce and debtors to the state whenever crop failure, equally with their own recalcitrance, occasions a shortage in their deliveries to the state. What a contrast with the position of agricultural producers in the United States! . . . Finally, there is reason to query the possibility of marked improvement in livestock output so long as the farmers do not own their stock and must collectively market the product as the state decides. Why should efficient husbandry be expected of them? Is it to be supposed that either patriotism or fear of punishment for neglect could, in the care and feeding of animals, substitute at all fully for the incentive of private ownership? I doubt it.

"Adding all of these doubts together, I am inclined to appraise as rather remote the probability that the Soviet Union under its present system of government will have achieved by 1959 a composition of the national diet much better than it was . . ."

² Presented at the Annual Meetings at Laramie.

I submit that in this excellent description of Soviet food potential, these personal judgments are misleading. Believe me, these ownership factors, which some people might call "natural instincts," are not necessarily so at all. I agree with Mr. Bennett that the Soviet Union cannot by decree affect rainfall and wind, but it can change many purely social, as opposed to physical, "instincts." I saw this kind of fanaticism in action in Germany in 1937, 1938, and 1939, and knew several brilliant young Russian officers in Korea in 1946, 1947, and 1948. I was completely aghast at what the religious fervor of a particular social dogma can do to the minds even of scientists.

But such fervent dogma is not limited to the communists. In this planned and controlled world, dogma could take possession of us. It could throw us into fascism or communism, government by a self-perpetuating elite. It exists even now, and has existed for a long time. I was also aghast when an intelligent young man speaking at the Forum of Labor, Agriculture and Industry, at Laramie, on behalf of a trade association serving utility companies, swinging his arms in a ministerial fervor of exhortation, damned all Americans who did not agree exactly that *he* and his stock of cliches represented the virtues of freedom, good, truth and beauty. Those who did not agree were "statists," a low form of "socialist."

He was for a controlled economy too, but the control was by a different and smaller group than most of us in America would be willing to trust.

In this world of planning and control of human affairs, where absolute truths are evaporating under the impact of scientific progress, what can we hold to? There is no completely satisfying answer. Perhaps the best we can do is be cautious of dogma and words without meaning, to do the best we can to close the gap between scientific progress and human institutions, and at all times to hold firmly before our eyes a big healthy black question mark.

THE INHERITANCE PROCESS AS VIEWED THROUGH
THE PROBATE COURT IN DANE
COUNTY, WISCONSIN

A COOPERATIVE research project, conducted jointly by the law school and the department of agricultural economics of the University of Wisconsin, was made as an exploratory investigation of the possibilities of using probate court records as a source for research in the fields of inheritance and capital accumulation.

The master sample for this study was selected from the death certificates recorded in the Register of Deeds' office for Dane County. The death of every resident of the county is recorded there regardless of where that resident died. Only decedents who had been legal residents of Dane County and over 20 years of age on death were selected. The five years 1929, 1934, 1939, 1941, and 1944 were selected for study. A 20 percent sample of death certificates for these years yielded a master sample of 983. Pertinent information from each death certificate sampled was recorded to supplement and check the information contained in the probate court records. For instance the death certificates provide more information as to occupation, age, sex, marital status, residence on death, etc. than do the estate records. Each schedule so obtained was checked against the index of probate court proceedings to determine whether an estate had been probated for the deceased person. If a record of any such proceeding was found, the type was recorded along with the file number of the record. In cases where any doubt existed as to whether the individual named in the death certificate and the probate court index were the same person, further checks were made through comparison of information on the death certificate with that in the folder for the estate. A sample of 415 estates was drawn by this procedure. Of these, 172 were testate estates, 195 were intestate estates settled by regular probate procedure, 33 were termination of joint tenancy only, and 15 were descent of lands proceedings.¹

Only 42.2 percent of the decedents in the master sample had an estate which passed through probate court. People who were classi-

¹ In these last two types of cases relatively little formal court action is required, and as a result the folders for these estates contain considerably less information than the regular estate folders. For this reason it has not been possible to include these estates in some of the tabulations.

fied² professional or proprietors (these were considered as one occupational group) had the highest proportion of estates probated of any occupational group with 66.2 percent of all such people having an estate. Farmers ranked second with 51.4 percent leaving an estate which passed through probate court. As might be expected a smaller proportion of women left estates than did men in any of the occupational groups. Only 33.1 percent of the women left estates. Inclusion of the 149 women undoubtedly had the effect of lowering the overall proportion of people leaving an estate—just as the inclusion of the 57 professional and proprietary people had the effect of raising the proportion. If these two extreme groups were excluded, the average proportion of people who left an estate would be 45.6 percent.

As might be expected, people between the ages of 70 and 90 had the highest proportion of estates (47.2 percent) which entered probate court. People between the ages of 20 to 50 (only 10.1 percent of all the people in the master sample) had the smallest proportion (30.0 percent) of estates probated. The proportion for people from 50 to 70 was 38.4 percent and for people over 90 it was 43.3 percent. This is about the pattern one might expect, since it is between the ages of 20 and 50 that the greatest effort is required to support and educate a family. It is logical to expect that people over 90 would also be less likely to leave an estate since most people of that age have been using up past accumulations of wealth to maintain themselves.

This study indicates that few people accumulate any sizable fortunes during their lifetime; 45.3 percent of those people having an estate which passed through probate court had a net worth on death of less than \$5,000.³ For Dane County as a whole this meant that about 77 percent of the people accumulated property worth less than \$5,000 free of debt during their lifetime. Only 10 percent of the estates studied had a net worth on death of \$25,000 or more. For Dane County as a whole, this meant that only about 4.2 percent of the people accumulated property worth more than \$25,000 during their lifetime.

The average net worth on death for all estates probated was \$11,500. The presence of 13 estates with a net worth of more than

² The occupational classification used here is based on the Works Progress Admin. Circular No. 2, *Occupational Classification and Code*, 1935.

³ Net worth as it is used here, includes the face value of all insurance, tax exempt property, and "gifts made in contemplation of death." The latter term is defined by law in Wisconsin as any gift made within two years of death.

\$50,000 had the effect of raising this average figure substantially. When considered by occupational groups, the professional people and proprietors (66.2 percent of them had estates probated) was the group with the highest net worth on death with an average of \$23,868. This group also had the greatest fluctuation in average size of estate on a year to year basis, with a low average of \$4,300 in 1939, and a high average of \$50,900 in 1944. Farmers as a group ranked second in size of net worth on death (51.4 percent of them had estates probated) with an average of \$11,400. The average net worth on death for all other people (41.1 percent of them had estates probated) was \$8,784.

The most striking feature of this analysis of the size of estates is the fact that even in Dane County, which should be more prosperous than the average county, there are very few people who manage to accumulate any substantial amount of wealth during their lifetime. This simple fact provides eloquent comment on the need for old age security programs. Five thousand dollars is certainly not enough money to provide security for the old age of any individual in this day and age, yet more than 77 percent of the residents of Dane County had less than this amount when they died.

A comparison was made between farmers, professional and proprietary people, and people in other occupational groups with respect to the composition of estates. Farmers definitely appear to have a larger proportion of their assets tied up in real estate than any other occupational group. They held farm real estate equal to 45.6 percent of the net value of the estate, and urban real estate equal to 7.3 percent of the net value of the estate. Professional and proprietary people, on the other hand, have farm real estate with a value equal to 3.3 percent of the net estate and urban real estate with a value equal to 35 percent of the net estate. People in other occupations have farm real estate with a value equal to 7.3 percent of the net estate and urban real estate with a value equal to 35.7 percent of the net estate.

People with smaller estates had a larger proportion of their holdings in real estate than did people with larger estates. This tendency was evidenced in all three occupational groups. In each occupational group, for the estates with a net value of less than \$5,000, the real estate holdings were valued at more than 90 percent of their net worth.

Professional and proprietary people appeared to possess fewer liquid assets in relation to their net estates than other occupational

groups. Cash and bank deposits for this group were equal in value to only 5.7 percent of the net estate. For estates of from five to fifteen thousand dollars net worth the proportion was 10.2 percent of the net estate. This was the highest proportion noted in any size group for people in this occupation. Farmers held cash and bank deposits worth 16.8 percent of their net estate. This proportion varied from a high of 23.1 percent for farmers with a net worth on death of less than five thousand dollars to a low of 15.2 percent for farmers with a net worth on death of from twenty-five to fifty thousand dollars. People in other occupations held cash and bank deposits valued at 14.1 percent of their net worth at death, with a high of 19.2 percent for those with net estates of less than five thousand dollars and a low of 10.3 percent for those with net estates of from fifteen to twenty-five thousand dollars.

The farmers in this sample made very little use of life insurance. The average face value of such insurance was equal to only 0.4 percent of the net estate. This may indicate that farmers as a whole depend principally on their investment in the farm business to provide security for their old age and for their dependents. Professional people and proprietors carried the largest relative amount of insurance with an average value equal to 25.1 percent of the net estate. This proportion for other people was 4.4 percent. Only 16.9 percent of the people with estates carried any life insurance at all. The amount of insurance carried by these people was also very small. In 43 out of the 70 estates where life insurance was carried the value of that insurance was less than \$2,500. In only 12 out of the 70 cases was the amount of insurance over \$9,500.

The question has frequently been raised as to whether or not a "will" makes any difference in the expense or time required to settle an estate. From this study it appears that there is no consistent savings in either time or over-all expense for settling an estate with a will when estates of comparable size are compared. Administrative expenses were further analyzed to get a more precise answer to this question. Attorneys' fees for testate and intestate estates of comparable size were about the same. There did seem to be a somewhat smaller charge for the personal representative in testate estates, but other expenses involved in closing the estates were sufficiently varied between the two kinds of estates to overshadow any slight advantage deriving from the smaller payment to the personal representative.

It is of further interest to note that in 8.6 percent of the estates with wills the disposition of property was identical with that provided by law. In another 11.4 percent of such estates the disposition was *almost* identical with that provided by law.

EDWARD H. WARD

University of Wyoming

ECONOMICS OF MINIMUM WAGES IN RELATION TO THE AGRICULTURAL LABOR MARKET

IN A discussion in this Journal of the economic effects of a minimum wage for farm workers on agricultural welfare and employment the conclusion was drawn that employment would be curtailed and agricultural poverty would be increased if a minimum wage were imposed.¹ It was suggested, first, that a minimum wage would result in higher labor costs, resulting in the "less intensive operation of . . . farm enterprises" and some curtailment of output. This reduction in output might be considerable in view of the fact that the farms which are responsible for the larger share of the total output are the very ones which employ wage-labor.² Secondly, there would be a tendency for farm operators to shift from the employment of hired labor to the fuller utilization of family labor or to transfer workers from the category of wage-earners to that of share-croppers.³ Thirdly, the curtailment in employment and the general inability of displaced agricultural workers to shift into other types of employment would tend to result in an even greater underemployment or unemployment in agriculture.⁴ Finally, farm operators would probably prefer hiring workers on an hourly basis rather than on a weekly or monthly basis with a corresponding drop in labor income.⁵

The conclusion that the minimum wage would result in a higher labor cost is based on the assumption that the increased costs cannot be offset by increased efficiency on the part of the workers or by an induced improvement of management techniques on the part of the employers. The argument that farm operators may

¹ Baughman, Earnest T., "A Note on Minimum Wages and Agricultural Welfare," this Journal, November 1946, pp. 1048-61.

² *Ibid.*, p. 1059.

³ *Ibid.*

⁴ *Ibid.*, p. 1060.

⁵ *Ibid.*

tend to displace hired workers in favor of family workers is based on the assumption that the impact of the minimum wage will bear substantially on farm operators who have a small wage-labor force and who find it possible to utilize such family labor. The conclusion that workers would be paid on an hourly rather than on a weekly or monthly basis also assumes that the impact of the minimum wage will be on farm operators who have a small wage labor force, for it is these farmers who generally employ workers on a monthly or weekly basis.

The analysis does not consider the possibility that certain monopsonistic (or oligopsonistic) elements may be present in the farm labor market with a possible "exploitation" of workers, i.e., a failure to pay workers the value of their marginal revenue product.⁶ In addition, though it points to possible greater agricultural poverty of the workers because of their immobility, it does not question whether such immobility may also not provide opportunities for "exploitation." To the extent to which such exploitation may exist, the imposition of a minimum wage should have little employment effects. Finally, the analysis does not distinguish between short-run and long-run effects and does not consider certain dynamic factors which may well tend to offset any unemployment effects of a minimum wage.

In this note an attempt will be made first, to discuss the reality of the assumptions and secondly, to indicate the extent to which the condition of "exploitation" may exist in agriculture.

It should be said at the outset, however, that no attempt is made in this note to arrive at a judgment "on balance" of the minimum wage in agriculture. It is proposed only to point to factors, overlooked in the reference article, which are believed relevant to empirical studies necessary to policy decisions in this perplexing field.

Substitutability of farm labor. To what extent will the introduction of a minimum wage in agriculture result in the displacement of farm workers because of higher labor costs? In answering this question two factors must be taken into consideration: the extent to which labor costs represent a small or large proportion of total costs; and the degree to which the employers may have been employing the best management or administrative procedures.

It has been pointed out that the substitution effect of the im-

⁶ This definition of exploitation follows that of Chamberlin, E. H., *Theory of Monopolistic Competition* (5th Ed.), pp. 182 ff.

position of a minimum wage may well be offset by certain other factors, such as increased productivity on the part of workers (because of the higher wages) or increased productivity as a result of employers' efforts. Increased productivity of the latter type may result from either the use of other resources (which may result in some drop in employment only if costs rise) or the adoption of management techniques which were previously available but not utilized. That is, the employers are "shocked out of lethargy." If an industry has a relatively low labor cost, the opportunities for improved management will usually be present.⁷

An analysis of wage costs in agriculture indicates that agriculture may well be an industry of low labor costs. In 1946, for example, the wages of farm labor represented about 18 percent of total production expenses.⁸ There is reason to believe that the imposition of a minimum wage may result in "shocking" some farm employers into improved methods of production.

If firms have been sheltered "from the full rigor of competition" and if they have been producing over a "prolonged period of rising business activity" one might well expect a certain degree of "administrative laxity."⁹ Both elements have been present in agriculture for the past years and it might well be that there is room for certain management adjustments. Such adjustments may result either in greater output with the same labor force or may even result in less work. But it may well be that the decrease in the number of man-hours required to complete one farm operation, due to improved organization, will yield the same income and no change in agricultural workers' poverty. Indeed, in agriculture, it may bring about the displacement of children and some women. Such displacement, rather than increasing agricultural poverty, may improve the welfare of this labor group.¹⁰

In certain areas, exploitative wages, if they exist (see below), may simply maintain inefficient farm operators. The imposition of a minimum wage may drive these growers out of business. But in the long run more capable men may replace them and the unemployment effects can be nil.¹¹

⁷ Stigler, George J., "The Economics of Minimum Wage Legislation," *American Economic Review*, June 1946, pp. 358, 359.

⁸ U. S. Department of Agriculture, *Agricultural Statistics* 1947, p. 536.

⁹ Reynolds, Lloyd G., "Toward a Short Run Theory of Wages," *American Economic Review*, Vol. 38, No. 3, June 1948, p. 298.

¹⁰ Dobb, Maurice, *Wages*, 1938, p. 131.

¹¹ Pigou, A. C., *Essays in Applied Economics*, pp. 50-51.

The substitution effects of the establishment of an agricultural minimum wage are not obvious. There are many considerations which must be taken into account, and such wage action, if reasonable, may not have any significant unemployment effects.

Displacement of hired workers by family workers. Although there may be a tendency to replace hired wage workers by family workers if an agricultural minimum wage were introduced, the amount of such replacement will depend, *inter alia*, upon the extent to which the smaller family-size farms employ wage workers.

In 1939 only 4.5 percent of the country's 6.1 million farms, or about 266,000 farms, were responsible for over 54 percent of the 1939 cash farm-wage bill. These farms accounted for only 5.6 percent of all family farm workers employed during 1939. For the United States as a whole almost two-thirds of the farm-wage bill in 1939 represented wages paid to workers hired by the day or week, or piece work and contract work.¹²

These data would seem to indicate that the displacement may not be substantial. And if the minimum wage legislation were applicable only to farms which employed, say, over four farm workers, the problem vanishes.

Wage-fixing combinations of farm employers. The lack of competition among farmers as buyers of labor and the existence of wage-fixing combinations among farm employers may put such employers in a position to "exploit" the farm workers.¹³ Such exploitation will take place if, in addition, the demand for workers is inelastic in the "market period."

If the demand for workers in the "market period" is such that there is a limit to the number of workers which can be hired the marginal revenue product curve would be indeterminate at this point. If the wage set by the wage-fixing combination is below this point, exploitation exists

The extent to which agricultural employers have combined as buyers of labor in order to depress wages below their competitive levels is not easily demonstrable chiefly because such information is seldom publicized. However, the hearings and reports of the

¹² Ducoff, Louis J., *Wages of Agricultural Labor in the United States*, U.S. Department of Agriculture, Technical Bulletin No. 895, July 1945, pp. 10, 12-13, and 29.

¹³ Machlup, Fritz, "Monopolistic Wage Determination as a Part of the General Problem of Monopoly," in *Proceedings of the Chamber of Commerce of the United States on Wage Determination and the Economics of Liberalism*, January 11, 1947, p. 56.

La Follette Committee on the farm labor situation offer considerable evidence that such combinations do exist in the California agricultural labor market and other areas.¹⁴

The La Follette Committee reported that the wages prevailing in many areas of agricultural production in California "are not customarily the result of collective bargaining procedures. Instead, they are subject to considerable employer control exercised on a uniform basis to avoid the effects of competition for or a local scarcity of labor."¹⁵ The "employers . . . are usually members of an association which has as one of its purposes the execution of policies respecting labor and labor relations. . . . They are concerned, among other things, with labor supply, the setting and adjusting of wage rates, and, more recently, with the questions of employee association, collective bargaining, and labor legislation."¹⁶

The La Follette Committee points out that these associations grew in number with the development of the wage-labor system. Typical of these associations are the Agricultural Labor Bureau of the San Joaquin Valley, the Farm Labor Service in Arizona, the Western Growers Protective Association, the Grower-Shipper Vegetable Association, the California Fruit Growers Exchange and the local exchanges associated with it, and the California Processors and Growers, Inc.¹⁷

It is interesting to note that "the groups of employers who meet to fix wage rates are usually organized and led by the large employers." The President of the Associated Farmers of California, Inc., stated that "we frequently find the large operators set the wage scales and he (sic) is the one that does actually create the wage scale and it is usually followed by the smaller farmers."¹⁸

There is evidence that growers in other states have banded together to fix wages. For example the wages of berry and apple pickers in the Puyallup Valley and Yakima and Wenatchee valleys were for many years set by the fruit growers associations. Evidence before the Tolan Committee indicates that Florida bean growers have met to establish a picking price.¹⁹

¹⁷ *Ibid.*, pp. 409-410.

¹⁸ *Ibid.*

¹⁹ Schwartz, Harry, *Seasonal Farm Labor in the United States*, p. 71.

Admittedly the evidence of employer wage-determination is sparse. But there are certain basic social, economic and institutional conditions which would seem to require such employer combinations. Farmers may fear, because of social ostracism, to set wages above the level of those set by their neighbors.

On the economic side it must be recognized that in the "market period" or short run the labor costs are strategic and, therefore, the farmers attempt to keep wages as low as possible. This problem is most acute in the harvest of fruits and vegetables since picking cannot be postponed. Furthermore, of all costs which growers must meet, the wage cost is more susceptible to individual grower decisions.²⁰ For these reasons the farmers seek, either through collective wage determination or the creation of large labor supplies, to keep the wages low.

The existence of local Farm Bureau or Farm Grange organizations and the development of cooperative marketing and shipping organizations provide the institutional framework within which growers can meet annually to set the wage rate jointly.

The bargaining position of the farm worker. Wherever employer wage-fixing combinations exist today one will usually find the employees organized. This, however, is not the case in the farm labor market. Not only are the farm workers disorganized, but the conditions of employer-employee relationships are such as to give the farm operator an opportunity to "exploit" the farm worker. And whatever attempts have been made by farm workers to organize have been resisted and, in some instances interfered with, by farm operators.

Although there have been many attempts to organize farm workers, such organizations have been "sporadic, scattered, and short-lived."²¹ The factors which have made the organization of these workers difficult have been economic, social, and political. "Their extreme mobility, the high seasonality of their work, and the low wage rates all combined to make unionization among them costly and, at the same time, created chronic problems for the communities in which they lived. The social status of seasonal farm workers was that of a lower caste, suffering poverty, depending upon relief, and lacking adequate facilities for education, housing, sani-

²⁰ Schwartz, Harry, *op. cit.*, pp. 68, 69.

²¹ United States Department of Labor, Bureau of Labor Statistics, Bulletin No. 836, *Labor Unionism in American Agriculture*, p. 406.

tation, and medical attention. They were, on the whole, politically impotent and, in many states, disfranchised."²²

Under such conditions, there are reasonable grounds for concluding that exploitation will take place since the organized farm employer has a greater strategic strength in bargaining with his workers. In the first place, he is accustomed to bargaining with workers. Secondly, the superior financial condition of the employer offers him an opportunity to resist the wage demands of the worker. On the other hand, the inferior financial status of the workers may reduce their mobility, lacking funds to seek alternative employment. And if wage setting by oligopsonistic combinations exists throughout a large agricultural area, even with funds, workers would have little basis for seeking other jobs. Finally, if a worker happens to be a tenant—or a member of a tenant's family—of the farmer, his failure to accept the offered wage may result in his displacement from the farm.²³ The latter problem is particularly acute in the southern part of the United States where a large portion of the seasonal farm labor force consists of this type of labor.

On balance, then, the bargaining strength of the growers appears to be much greater than that of the farm workers, and, on the basis of the social, economic, and political conditions surrounding the wage bargain, it would be reasonable to assume that a certain degree of "exploitation" exists.

Immobility of farm workers. It has been stated that "probably the strongest case for the creation of labor monopolies to avoid monopsonistic wage determination" may be made when (1) "many labor markets are geographically or occupationally so isolated that employers have no competition in their purchase of labor" or when (2) "chronic unemployment makes employed labor practically immobile and eliminates employers' competition for labor."²⁴ Thus, the immobility of the workers offers the wage-fixing combination an opportunity to push the wage below the marginal revenue product.

One must distinguish between two groups of seasonal farm labor, namely, the local resident group and the transient, migratory workers. In many cotton areas of the South is found the first type. Each year wives and children of tenant farmers or sharecroppers

²² *Ibid.*

²³ Pigou, A. C., *The Economics of Welfare* (3rd ed.), Macmillan and Co., p. 559.

²⁴ Machlup, *op. cit.*, pp. 56, 58-59.

are employed in the cotton harvest and at the end of the farm operation they leave the labor market. The latter group consists of workers who travel from area to area in search of work and are employed to meet the requirements of the seasonal peaks.

The local, resident seasonal worker is, of course, highly immobile. He is poor in financial resources and unable to move to other areas (particularly in the short-run); the social ties to his home and family are strong; and he is usually ignorant of other employment opportunities. Fear of displacement as a tenant or sharecropper will usually prevent him from "bargaining" for higher wages. And in instances when this local resident, seasonal worker has demanded, or was in a position to demand, higher wages, the growers have advertised for and brought in workers from other areas to maintain wages at the "going rate."²⁵

During the past war period farmers pursued a number of policies in order to preserve their farm labor supply.²⁶ High license fees for labor recruiting agents, special deferment provisions for farm workers under the Selective Service Act, and the provision under the Farm Labor Transportation Program that no workers were to be recruited in any county for work in other areas without prior approval of the county agent who must certify that the county had a surplus of labor are examples of methods employed to "freeze" workers in their areas of usual employment.

The transient, migratory worker who moves from crop to crop would appear at first to be highly mobile. He is, until he reaches the place of employment. Employers have used a variety of devices to bring into the area a "surplus" of labor. Such devices have included the flooding of areas with handbills, local newspaper advertising, radio broadcasts, etc., with the subsequent disorganization of the farm labor market.²⁷ Once the workers have arrived at the area of "need," they have no alternative but to accept the wage offer.

The economic factor here too plays an important role in forcing growers to adopt such practices. In view of the need for maintaining control over the wage, only a surplus of workers could continue

²⁵ See Report of Select Committee on *Interstate Migration*, House Report No. 369, 77th Congress, 1st Session, pp. 364 ff., for many illustrations of this practice. (Hereafter referred to as the Tolan Committee Report.)

²⁶ Kaufman, Jacob J., "Farm Labor During World War II," this Journal, February 1949, pp. 131 ff

²⁷ Tolan Committee Report, p. 364 ff.

such control. Once workers are employed various devices are used to prevent them from "skipping" to other jobs. For example, "bonuses" (actually, "holdbacks") are paid to workers provided they stay on until the harvest is completed; or credit is extended to workers so that they are in debt at the beginning of the harvest and must remain on the farm until the end of the season in order to pay off the debt.²⁸

Short Run vs. Long Run Effects. The short run substitution effects of a minimum wage in agriculture may be considerably limited. Particularly in the harvesting of such crops as fruits, vegetables, and cotton (so far) there are few substitutes for hand labor. "Tractors can't work between tightly packed rows and the machine that can harvest broccoli and egg plant and tomatoes has yet to be built."²⁹

The substitution effect may, rather, be one of a long-run nature, but in the long run dynamic factors may play an important role.³⁰ "Over any substantial period of time there are such pronounced changes in productivity, consumer preference, and the general condition of business that the relationship (i.e., between the imposition of a minimum wage and the curtailment of output and employment) is fatally beclouded."³¹

Conclusions

There is some evidence that "exploitation" may exist in agriculture as a result of combinations of employers for the purpose of wage-fixing, and of a considerable degree of labor immobility. Although the evidence of such wage-fixing combinations is limited, certain social and economic forces are at work and certain institutional structures exist which make such combinations necessary (from the point of view of the farmer) and possible. The immobility of workers is not only the result of the political, social, and economic environment of the workers, but also of the direct activities of the growers themselves. To the extent that these two elements—oligopsony and labor immobility—exist in the farm labor market the imposition of a minimum wage may be justified in order to wipe out the existing "exploitation" without any unemployment

effects. In other words the competitive solution is not applicable under these conditions.

Furthermore, there is some basis for questioning the substitution effects, even under competitive conditions, of the imposition of a minimum wage for agricultural workers. And, in some instances, such substitution (if it does take place) may not necessarily increase agricultural poverty. The possible elimination of women and children from the farm labor market and the displacement of inefficient farmers may have certain desirable economic effects.

JACOB J. KAUFMAN

The University of Buffalo

SOME PROBABLE EFFECTS OF TAXATION ON FARMERS' MARKETING PRACTICES*

DURING the last decade farmers in the United States experienced a period of high-level production and relatively high commodity prices. This combination of favorable circumstances resulted in the highest level of farm incomes in the history of American agriculture. Although incomes were not uniform throughout the farming area over this entire period, in general, total farm production, prices, and incomes have been consistently high since 1941. Paralleling the price and income situation during this period has been a consistent tendency to broaden the income-tax base and to increase tax rates. This combination of circumstances has brought about a phenomenal increase in farmers' tax contributions to the Federal Government.

The purpose of this article is to explore the hypothesis that specific phases of Federal tax policies and administrative procedures influence farmers' marketing practices. It is essential first to present certain background information.

In 1913 the 16th Amendment to the Constitution of the United States was adopted permitting Congress to levy income taxes "without apportionment among the several States, and without regard to any census or enumeration." Because of liberal personal exemptions (\$4,000 for married couples) the Federal income tax in the early years 1913 to 1917 touched farmers' incomes to only a minor extent. Tax rates at that time were modest, the "normal"

* This paper represents the author's personal views on the subject under discussion.

tax in 1913 being one percent with no surtax until taxable income passed \$20,000. It was not until the high price and income years following World War I that the income tax assumed any importance in the business affairs of farmers.

From 1921 to 1940, the number of farmers paying Federal income taxes and the amounts paid were still of only minor significance. In fact, as late as 1939, according to the Bureau of Internal Revenue's classification of returns by industries or types of businesses, only about 140,000 businesses were listed in the farming category.¹

Beginning with 1940, substantial increases in Federal tax obligations were effected by merely lowering personal exemptions. Returns for 1941 contained over a million in the farm group. Changes in the revenue code from 1941 through 1943 imposing higher rates and lowering personal and dependency exemptions brought many farmers into the income-tax-paying fraternity for the first time.

Although no tabulations are available as to the number of farmers reporting for the latest tax years, estimates have been made of the amount of taxes paid. Based on available data relating to income distribution and tax payments for sample groups of farmers, the Bureau of Agricultural Economics has estimated that Federal income-tax payments of farmers during the last few years were as follows:²

<i>Year Paid</i>	<i>Amount</i>	<i>Year Paid</i>	<i>Amount</i>
1941	\$ 15,000,000	1945	\$725,000,000
1942	50,000,000	1946	720,000,000
1943	425,000,000	1947	760,000,000
1944	275,000,000	1948	960,000,000

The question arises, in what manner does the frequency and amounts of farmers' income-tax payments influence their marketing schedules and practices. One clue to an answer to this question lies in the method of accounting for or, more appropriately, methods of reporting incomes for tax purposes. Under the present code a farmer may use either the cash or accrual basis for reporting income.

Basically, the cash method allows a business firm, for tax-reporting purposes, to include all cash income actually or constructively received and to deduct all allowable expenses paid out during

¹ Isaac, G. J., "Farmers Taxes," *Agr. Finance Rev.* BAE Vol. 9, Nov. 1946, p. 12.

² *Agr. Finance Rev.* BAE Vol. 11, Nov. 1948, p. 90.

the tax year, regardless of the time the income was earned or the expenses were incurred. In actual practice it is estimated that 90 percent of the farmers who file income tax returns use the cash method of reporting.

The accrual basis is really an inventory method of reporting income. Income reported on the accrual basis includes all income earned during the taxable year from sales made in that year, regardless of when payment is received.³ In addition, increases in inventory values at the end of the year compared with the beginning of the year must be included. Allowable expenses include all business operating costs incurred during the year, whether paid or not, and any decrease in inventory values at the end of the year compared with the beginning of the year.

Obviously, the accrual method of reporting requires a more detailed and complex system of bookkeeping than the cash method. Some few farmers find it advantageous (tax-wise) to use the accrual method, but the vast majority find the cash method more desirable. It is important at certain times for this large segment of cash-reporting farmers to act or to forego action on specific dates within the year. For example, tax obligations may be materially altered by the execution of a sale or delay of execution for a period of as little as 24 hours.

During 1946 and 1947 there was much public discussion of the probability of Federal tax reduction legislation. Perhaps anticipating a lower tax rate in 1947 some farmers carried over their 1946 crops and sold them in 1947. Important tax reductions did not, however, materialize in 1947. Farmers who had carried over and sold their crop in 1947 found themselves in the embarrassing position at the close of the calendar year of having another bountiful crop on hand to be disposed of at exceptionally favorable prices and pay income taxes accordingly, or run the risk of carrying the new crop over into another year. If the farmer sold his 1947 crop (having carried all or substantially all of the 1946 crop over), he would be thrown into a higher income tax bracket and, in effect, would be forced into paying a higher rate of tax in that year on two years' income.

With each new income bracket present surtax rates increase

³ Tax Court cases have introduced many refinements as to when and how it may be determined that income has been received. Rulings on specific cases, however cannot be considered as having any general applicability.

significantly. In contrast to the four-percent rate in effect in 1917 on taxable incomes in excess of \$2,000 and a surtax rate of only one percent on incomes from \$5,000 to \$7,500 the present basic tax is \$400 plus 22 percent of the excess over \$2,000. To appreciate the tax significance of income increments of two, four, six, and ten thousand dollars it is necessary again only to review a sample of the schedule of rates in the Bureau of Internal Revenue's 1948 information pamphlet, "How to Prepare Your U.S. Income Tax Return." Excerpts from the 1948 Federal Income Tax Rate Schedule

Over \$ 2,000 but not over \$ 4,000—\$ 400, plus 22% of excess over \$ 2,000
Over \$ 4,000 but not over \$ 6,000—\$ 1,260, plus 30% of excess over \$ 4,000
Over \$ 6,000 but not over \$ 8,000—\$ 1,860, plus 38% of excess over \$ 6,000
Over \$ 8,000 but not over \$ 10,000—\$ 2,640, plus 46% of excess over \$ 8,000
Over \$ 10,000 but not over \$ 12,000—\$ 3,400, plus 54% of excess over \$ 10,000
Over \$ 12,000 but not over \$ 14,000—\$ 4,240, plus 62% of excess over \$ 12,000
Over \$ 14,000 but not over \$ 16,000—\$ 5,060, plus 70% of excess over \$ 14,000
Over \$ 16,000 but not over \$ 18,000—\$ 5,860, plus 78% of excess over \$ 16,000
Over \$ 18,000 but not over \$ 20,000—\$ 6,640, plus 86% of excess over \$ 18,000
Over \$ 20,000 but not over \$ 22,000—\$ 7,400, plus 94% of excess over \$ 20,000
Over \$ 22,000 but not over \$ 24,000—\$ 8,140, plus 102% of excess over \$ 22,000
Over \$ 24,000 but not over \$ 26,000—\$ 8,860, plus 110% of excess over \$ 24,000
Over \$ 26,000 but not over \$ 28,000—\$ 9,560, plus 118% of excess over \$ 26,000
Over \$ 28,000 but not over \$ 30,000—\$ 10,240, plus 126% of excess over \$ 28,000
Over \$ 30,000 but not over \$ 32,000—\$ 10,900, plus 134% of excess over \$ 30,000
Over \$ 32,000 but not over \$ 34,000—\$ 11,540, plus 142% of excess over \$ 32,000
Over \$ 34,000 but not over \$ 36,000—\$ 12,160, plus 150% of excess over \$ 34,000
Over \$ 36,000 but not over \$ 38,000—\$ 12,760, plus 158% of excess over \$ 36,000
Over \$ 38,000 but not over \$ 40,000—\$ 13,340, plus 166% of excess over \$ 38,000
Over \$ 40,000 but not over \$ 42,000—\$ 13,900, plus 174% of excess over \$ 40,000
Over \$ 42,000 but not over \$ 44,000—\$ 14,440, plus 182% of excess over \$ 42,000
Over \$ 44,000 but not over \$ 46,000—\$ 14,960, plus 190% of excess over \$ 44,000
Over \$ 46,000 but not over \$ 48,000—\$ 15,460, plus 198% of excess over \$ 46,000
Over \$ 48,000 but not over \$ 50,000—\$ 15,940, plus 206% of excess over \$ 48,000
Over \$ 50,000 but not over \$ 52,000—\$ 16,400, plus 214% of excess over \$ 50,000
Over \$ 52,000 but not over \$ 54,000—\$ 16,840, plus 222% of excess over \$ 52,000
Over \$ 54,000 but not over \$ 56,000—\$ 17,260, plus 230% of excess over \$ 54,000
Over \$ 56,000 but not over \$ 58,000—\$ 17,660, plus 238% of excess over \$ 56,000
Over \$ 58,000 but not over \$ 60,000—\$ 18,040, plus 246% of excess over \$ 58,000
Over \$ 60,000 but not over \$ 62,000—\$ 18,400, plus 254% of excess over \$ 60,000
Over \$ 62,000 but not over \$ 64,000—\$ 18,740, plus 262% of excess over \$ 62,000
Over \$ 64,000 but not over \$ 66,000—\$ 19,060, plus 270% of excess over \$ 64,000
Over \$ 66,000 but not over \$ 68,000—\$ 19,360, plus 278% of excess over \$ 66,000
Over \$ 68,000 but not over \$ 70,000—\$ 19,640, plus 286% of excess over \$ 68,000
Over \$ 70,000 but not over \$ 72,000—\$ 19,900, plus 294% of excess over \$ 70,000
Over \$ 72,000 but not over \$ 74,000—\$ 20,140, plus 302% of excess over \$ 72,000
Over \$ 74,000 but not over \$ 76,000—\$ 20,360, plus 310% of excess over \$ 74,000
Over \$ 76,000 but not over \$ 78,000—\$ 20,560, plus 318% of excess over \$ 76,000
Over \$ 78,000 but not over \$ 80,000—\$ 20,740, plus 326% of excess over \$ 78,000
Over \$ 80,000 but not over \$ 82,000—\$ 20,900, plus 334% of excess over \$ 80,000
Over \$ 82,000 but not over \$ 84,000—\$ 21,040, plus 342% of excess over \$ 82,000
Over \$ 84,000 but not over \$ 86,000—\$ 21,160, plus 350% of excess over \$ 84,000
Over \$ 86,000 but not over \$ 88,000—\$ 21,260, plus 358% of excess over \$ 86,000
Over \$ 88,000 but not over \$ 90,000—\$ 21,340, plus 366% of excess over \$ 88,000
Over \$ 90,000 but not over \$ 92,000—\$ 21,400, plus 374% of excess over \$ 90,000
Over \$ 92,000 but not over \$ 94,000—\$ 21,440, plus 382% of excess over \$ 92,000
Over \$ 94,000 but not over \$ 96,000—\$ 21,460, plus 390% of excess over \$ 94,000
Over \$ 96,000 but not over \$ 98,000—\$ 21,460, plus 398% of excess over \$ 96,000
Over \$ 98,000 but not over \$ 100,000—\$ 21,440, plus 406% of excess over \$ 98,000
Over \$ 100,000 but not over \$ 150,000—\$ 67,820, plus 89% of excess over \$ 100,000

Rates go as high as 91 percent on bracketed incomes in excess of \$200,000 but relatively few farmers are concerned with rates applicable to incomes above the \$100,000 level. In the event that receipts from sale of two crops have to be accounted for in the same tax year, a considerable number of farmers would have incomes above the \$100,000 figure but in proportion to the total number of income-tax paying farmers the percentage in this group would still be very low. Prevailing high prices, high-level production and high tax rates of recent years have tended to make farmers more accounting conscious. The increasing surtax rates on the higher income brackets are a strong inducement to equalize incomes between years as nearly as possible.

In the absence of primary supporting data, determination of the specific degree of importance to attach to the influence of income tax considerations on farmers' marketing decisions is not within the purview of this paper. Such an attempt would have to be approached through a lengthy process of establishing statistical models which would make possible weighting of the dominant motivating forces that influence farmers' marketing practices or patterns. There is, however, strong evidence to indicate that income tax considerations do enter into farmers' marketing decisions. The following table, illustrative of data compiled on important grain crops, shows that for the last three crop years larger than average movements of wheat from farm to market took place during the month of January. Again it should be pointed out here that

* (10 year average).

the great majority of farmers use the calendar-year basis for tax-reporting purposes.

There are no doubt several factors that contribute to the deviation from the general pattern of wheat sales in the month of January. It is difficult to trace the significance of any single motivating factor, but by the process of elimination certain of the factors generally considered to be determining influences may be dismissed.

For the grain crops price, storage, and feed considerations are generally recognized as primary influences affecting farmers' marketing decisions. These three considerations do not, however, appear to be paramount during the time period which is, from the tax consideration standpoint, crucial. It can be assumed that in most instances the storage problem has been resolved by the month of January, thus eliminating this factor as an important influence on sales in January of each of the calendar years considered.

Grain held over for feed purposes is not customarily disposed of until some rather tangible indications of crop prospects for the en-

suings year are in evidence. There are few indications of prospects for the new crop as early as January.

It does not appear that fluctuations in prices between the months shown in Table 2 were significant enough to have had any appreciable influence in shaping farmers' decisions to sell in the first month (January) of each of the three new calendar years as compared with the previous month of the closing year. In fact, the theory is often advanced that farmers are inclined to sell on a declining market. The foregoing price figures show, in the case of wheat, that prices were tending upward in the first month (January) of the three years shown. Concern over prices, therefore, could hardly be the cause of the relatively heavy sales of wheat in the month of January.

Conclusions

The hypothesis that Federal income tax policies influence marketing decisions of farmers has not yet been adequately explored to determine the actual degree of importance. But every avenue thus far explored indicates that they do influence the marketing process. Although considerable hearsay evidence could be offered in support of the hypothesis, final judgment must await further evidence. It is hoped that this working hypothesis and the general interest exhibited in proposed research to study the problem in detail will lead to a complete analysis of the role of taxation in the marketing and distribution system.

To the extent that adjustments in the marketing program of an individual farmer or group of farmers for tax consideration purposes have a stabilizing influence on farm incomes, such adjustments might be considered highly desirable. It is, however, quite improbable that any net stabilizing influence will be gained from such practices.

Although other motivating forces may predominantly govern the marketing decisions of farmers, recent progress in developing storage facilities for both staple and certain perishable commodities lends increasing importance to the "tax angle" in the market place.

SAMUEL L. CROCKETT

LONG-TIME ECONOMIC PROSPECTS FOR
AGRICULTURE?

HAVE agricultural economists in their outlook and price policy work in recent years given sufficient attention to the possibility that we are developing new powerful factors in our economy which may modify the usual postwar behavior of prices? They may also modify greatly the usual business cycle over the next several decades. In his recent book, *Money, Debt, and Economic Activity*, A. G. Hart finds in the government's role of adjudicating conflict between the centers of great political-economic power—corporations, labor unions and organized agriculture—a strong and persistent inflationary pressure. Arguing that government price-wage policy is subject to claims from these three powerful groups, and that any controls of the prices of their particular commodities or services are very unpalatable to each, Hart contends that legislators will naturally look for the easy way out. This they will find to be in yielding a little to each group. "Farmers may want to see lower wages, but will always accept higher farm prices instead. Trade-unionists would like food cheaper, but can be consoled with higher wages. Businessmen would like both sets of prices lower, but are cheerful as long as they can add what they regard as suitable profit margins to the costs originating in wages and raw material prices. Thus, the politician has a perpetual temptation to please one group by helping its selling prices rise and then to compensate others by doing the same for them. The result is 'log-rolling inflation.'"¹

Discussing the same general problem, Calvin B. Hoover writes, "With all organizations of claimants for shares of the national income demanding incomes higher than those which can be granted out of real national income, the temptation to grant everybody larger shares—and to depend upon reducing the shares to tolerable proportions through allowing rises in the general price level—becomes terrifically great."² This pressure, he contends, grows out of the political necessity of any party, either of the "left" or of the "right," to maintain reasonably "full employment" at any cost. Keynes found a "built in" tendency of the economy to over-save

¹ Hart, A. G., *Money, Debt, and Economic Activity*, Prentice-Hall, New York, 1948, p. 480.

² Hoover, Calvin B., "Keynes and the Economic System," *The Journal of Political Economy*, LVI, No. 5 (Oct 1948) p. 401.

(in relation to investment) as the economy passed from the self-regulatory stage of effective competition to that of widespread corporate organization. But this unbalance is now in prospect of being reversed as a consequence of the increased proportion of total economic activity now being channelled through government. Not only are legislators naturally induced to pressure the price-level upward as a means of resolving industrial conflict, but also obliged, if they wish to stay in power, to overspend in relation to savings in order to maintain "full employment." The consequence: "the 'inflationary gap' is more likely to be a continuing problem for our present modified form of capitalism than is the (prewar) discrepancy between the propensity to save and the inducement to invest."² To the analyses of these two economists should, of course, be added the influences on our economy of our emphasized world leadership and the continuing "cold war."

Most long-term outlook and price policy proposals for agriculture have been fabricated upon a presumption of recurring periods of general deflation; their objectives have been principally to protect farmers against undue hardship during these periods. One wonders how long-time outlook statements should be modified and what kind of analyses and proposals in the price policy field would be appropriate should a future such as these two men foresee become a reality. One wonders also just how much exploring of this question has been done, just in case the conclusions of these men *might* be right!

LEGISLATION PASSED BY THE 81ST CONGRESS, 1ST SESSION

LAWS OF INTEREST TO AGRICULTURAL ECONOMISTS LISTED IN CHRONOLOGICAL ORDER

PUBLIC LAW 11 (S. 548) EXPORT CONTROL ACT OF 1949 (approved February 26, 1949). Continues export-control authority until June 30, 1951, or such earlier date as Congress or the President may determine. Provides that controls shall not be exercised on agricultural commodities during any period for which the

supply is determined by USDA to be in excess of domestic requirements.

Public Law 28 (H.R. 128) COTTON ACREAGE ALLOTMENTS (approved March 29, 1949). Amends the AAA Act of 1938 so as to provide that state, county, and farm acreage allotments and yields for cotton for any year after 1949 shall be computed without regard to yields or to the acreage planted to cotton in 1949.

Public Law 38 (H.R. 2101) RACC DISASTER LOANS (approved April 6, 1949). Abolishes the Regional Agricultural Credit Corporation and transfers its functions to the Secretary of Agriculture. Authorizes the Secretary to make loans to farmers and stockmen for any agricultural purpose in any area or region where he finds that a production disaster has caused a need for agricultural credit not readily available from other responsible sources.

Public Law 47 (S. 1209) ECA AUTHORIZATION (approved April 19, 1949). Among other things, provides that 12½ percent of wheat shipments from the United States shall be in the form of flour; amends the provision regarding surplus agricultural products so as to provide that a "class, type, or specification" of a commodity may be determined by the Secretary to be surplus.

Public Law 85 (S. 900) COMMODITY CREDIT CORPORATION CHARTER ACT AMENDMENTS (approved June 7, 1949). Amends the Commodity Credit Corporation Charter Act in the following respects: Returns CCC to the supervision and direction of the Secretary. Increases the number of members of the Board of Directors from five to seven. Provides that the Secretary serve as Chairman of the Board. Removes the limitation upon the appointment of directors who are otherwise employees of the Federal Government; provides for a bi-partisan advisory board of five members.

It permits the Corporation to acquire real property or any interest therein for the purpose of providing storage adequate to carry out effectively and efficiently any of the Corporation's programs.

Public Law 99 (H.R. 3181) WATER FACILITIES LOANS (approved June 10, 1949). Increases from \$50,000 to \$100,000 the monetary limitation on individual projects which may be undertaken under the Water Facilities Act of 1937.

Public Law 155 (H.R. 5240) FATS, OILS, RICE IMPORT CONTROLS (approved July 1, 1949). Amends the Second War Powers Act, 1942, so as to continue until July 1, 1950, the authority for exercis-

ing, administering, and enforcing of import controls with respect to fats and oils and rice and rice products.

Public Law 171 (S. 1070) **HOUSING ACT OF 1949** (approved July 15, 1949). Authorizes the Secretary, through the Farmers Home Administration, to make loans, for a period up to 33 years and at not over 4 percent interest, to owners of adequate farms who are otherwise unable to finance safe and sanitary housing and other needed farm building improvements for themselves or others working on the farms. The loans will not require a first mortgage on the farm property and may be secured by the farmers' equity in the farms. Authorizes similar loans, supplemented by annual contributions, to owners whose farms are not presently adequate, but which may be brought to an adequate basis through a satisfactory program of enlargement. Authorizes combination loans and grants for minor improvements and repairs to farm dwellings and farm buildings, in order to make them sanitary and safe, on farms which are neither adequate nor potentially adequate. Title IV authorizes a program of technical research and studies on housing.

Public Law 268 (H.R. 3825) **FEDERAL CROP INSURANCE ACT AMENDMENTS** (approved August 25, 1949). Authorizes an increase each year in the number of counties in which insurance can be offered. Removes the clause requiring indemnities to be paid on a pro-rata reduced basis, beginning with the crop year 1950, when indemnities exceed premiums.

Public Law 272 (S. 1962) **COTTON ACREAGE ALLOTMENTS AND MARKETING QUOTAS** (approved August 29, 1949). Authorizes the proclamation of a national marketing quota for cotton whenever the total supply exceeds the normal supply, as defined in the act. Provides for the proclamation of a national acreage allotment which will produce the amount of the proclaimed quota. For 1950 and 1951 special provision is made for the distribution of the national acreage allotments to states and counties. Contains provisions relating to wheat and peanuts to provide for certain minimum farm wheat acreage allotments for 1950 and for a minimum national peanut acreage allotment for 1950 of 2,100,000 acres. Provision is also made for the apportionment of the national peanut acreage allotment in 1951, and thereafter, by increasing or decreasing 1950 state acreage allotments proportionately as the national allotment is increased or decreased.

Public Law 307 (H.R. 1211). **TRADE AGREEMENTS** (approved

September 26, 1949). Repeals the Trade Agreements Extension Act of 1948 and extends the Trade Agreements Act until June 12, 1951, in substantially the same form as before the 1948 amendments.

Public Law 352 (S. 2116) **PUBLIC WORKS** (approved October 13, 1949). Authorizes the appropriation of \$100,000,000 for advances by GSA to the States for advance planning of non-Federal public works.

Public Law 348 (S.J. Res. 53) **REFORESTATION AND REVEGETATION** (approved October 11, 1949). Declares the policy of Congress to accelerate and provide a continuing basis for reforestation and revegetation of forest lands. Authorizes for reforestation and revegetation through the Forest Service appropriation of \$4,500,000 for fiscal year 1951, increasing to \$13,000,000 in 1955.

Public Law 361 (H.R. 2514) **FINANCIAL ASSISTANCE TO HOMESTEAD ENTRYMEN** (approved October 19, 1949). Permits the extension of loan assistance under the Bankhead-Jones Farm Tenant Act and the act of August 28, 1937, known as the Water Facilities Act, to persons who are acquiring farms by means of homestead entry on public lands or who are purchasing farms on reclamation projects, and who are otherwise eligible for such loans.

*Acts Passed by Both Houses of Congress But Not Yet
Signed by the President as of October 24, 1949*

H.R. 2960. **LOANS FOR RURAL TELEPHONES**. Authorizes the Administrator of the Rural Electrification Administration to make loans for the purpose of financing the improvement, expansion, construction, acquisition, and operation of facilities to render telephone service in rural areas. The loans will bear interest at 2 percent and are subject to the same terms and conditions as loans made for rural electrification.

H.R. 4146. **NATIONAL MILITARY ESTABLISHMENT APPROPRIATION FOR 1950**. Carries the following provisions: That none of the funds appropriated in this title shall be used for the payment of any subsidy on agricultural or other products; the Secretary of the Army is authorized to purchase from the CCC any food products owned and stored by such Corporation which the Secretary determines to be of a satisfactory quality for the use of the Military Establishment, or for civilian feeding in occupied areas.

H.R. 2296. **COOPERATIVE FORESTRY PROGRAMS BILL**. Amends

the Clarke-McNary Act so as to increase funds for forest fire protection from \$9,000,000 to \$20,000,000 by successive yearly increases, and increases the yearly appropriation authorization for growing forest tree planting stock from \$100,000 to \$2,500,000 by successive annual increases; expands the Federal-State education program for small forest landowners by increasing the annual appropriation authorization to \$500,000.

H.R. 5856—FAIR LABOR STANDARDS ACT OF 1949—Raises minimum wages of covered workers to 75 cents an hour.

H.R. 6305—INTERNATIONAL WHEAT AGREEMENT ACT OF 1949—The President is authorized, acting through the CCC, to make available or cause to be made available, such quantities of wheat and wheat flour and at such prices as are necessary to fulfill the obligations of the United States under the International Wheat Agreement of 1949.

H.R. 3699—FEDERAL LAND-BANK LOANS—Amends the Federal Farm Loan Act to authorize loans through National Farm-Loan Association in Puerto Rico, to increase the limitations on Federal Land-Bank loans to any one borrower from \$50,000 to \$100,000.

H.R. 5345—AGRICULTURAL ACT OF 1949—Provides price supports at 90 percent of parity if acreage allotments or quotas are in effect for basic commodities in 1950; at 80 to 90 percent in 1951; and 75 to 90 percent in 1952 and thereafter.

Whole milk, butterfat, and the products of such commodities are to be supported at between 75 percent and 90 percent of parity. Price supports for wool, including mohair, tung nuts, honey, and Irish potatoes are mandatory between 60 and 90 percent of parity. Price support for non-basic agricultural commodities, other than the designated commodities, is permissive at any level not in excess of 90 percent of parity.

The modernized parity formula contained in the Agricultural Act of 1948 is amended to include wartime subsidy payments and wages paid hired farm labor. However, in the case of the basic commodities, the use of the old parity price definition is required at any time during the four year period beginning January 1, 1950, if that price is higher than the modernized parity.

The Secretary is directed, so far as practicable, to announce the level of price support for field crops in advance of the planting season and for other agricultural commodities in advance of the beginning of the marketing year or season.

BOOK REVIEWS

Readings on Agricultural Policy, Edited by O. B. Jesness, Univ. of Minnesota. The Blakiston Co., Philadelphia. 1949. Pp. xi, 470, \$4.50.

Readings on Agricultural Policy is a collection of previously published articles dealing with various phases of agricultural policy. A good job has been done. This book consists of twenty-three papers by twenty-one different individuals and eleven articles from committee reports. It is definitely not a textbook, but can be a valuable reference for students of economics and agricultural economics—especially those taking courses in agricultural policy.

The book is divided into four parts: (1) Background, (2) Price and Production Adjustments, (3) International Trade and Relations, (4) Land and Rural People. In a collection of published articles on closely related topics, there is naturally considerable repetition due to each writer presenting background material for his major points. No attempt will be made to evaluate or summarize the contents of the various articles.

Part 1 presents background material on agricultural policy. It contains five papers and takes up about one-eighth of the book. The first two papers contain fundamental material dealing with the relationship of agriculture to the national economy. The next deals with farm prosperity, followed by a paper on what farmers want. The concluding paper of this section stresses the importance of the general welfare approach in developing agricultural policy.

This section does not include a presentation on world agriculture, the nature of farming in other lands, the extent to which it is carried on by peasants, and the broad aspects of agricultural policy in other nations. A paper dealing with these broad aspects would be helpful in orienting the thinking of students studying our own agricultural policy.

Part 2, dealing with price and production adjustments, contains fifteen papers and takes up nearly one-half of the book. This section starts out with a history, written in sympathetic vein, of the development of agricultural policy since World War I. This is followed by a paper on the evolution of parity. Several of the papers in this section discuss various aspects of parity. Over half the articles in Part 2 were parts of reports on agricultural price policy by various committees, including the Committee on Postwar Agricultural Policy of the Association of Land Grant Colleges and Universities,

various committees of the Farm Economic Association, and the House Special Committee on Postwar Economic Policy and Planning of the seventy-ninth Congress. In the main, these reports deal with the general aspect of price and production policy. Other articles in this section present individual opinions on the fundamentals of a sound agricultural price policy and, in some cases, their suggested solutions to the problems involved.

The selection of papers to be included for this section was no doubt difficult in order to present a fair balance between those in the profession who have considerable faith in government programs and those who do not share this view. From an over-all point of view, this section might have been strengthened if more analysis had been presented on the demand approach—such things as the Stamp Plan, School Lunch, Relief Feeding, Animal Agriculture, and the like.

Part 3 contains five papers dealing with international trade and relations. It starts out with a paper on the United States and World Trade, which is followed by a discussion of reconciling agricultural and foreign trade policies. The remaining papers deal, to a considerable extent, with a proposed World Trade Board and with commodity agreements.

This section contains too much on commodity agreements and not enough on fundamentals of trade. There was not enough discussion on the place and responsibilities of the United States in foreign affairs, the dollar shortage, our need to develop imports, and the like. The editors had to select from things written. Here again, perhaps, is a case where too little has been written on fundamentals in proportion to writings on specific programs of action.

Part 4 deals with land and rural people. It contains nine papers. The need for a land policy was discussed, followed by a broad presentation dealing with our major land use problems, and a paper on issues in federal land management in the western states. The section contains papers on land tenure, problems of farm laborers and share croppers, the problems of southern agriculture and concludes with a presentation on rural living and social facilities.

Three things impressed the reviewer from reading these articles concurrently: First, most economists were too pessimistic on farm prices for the immediate postwar period. Second, most economists discuss and attack parity as if it were the actual price received by

farmers. History indicates that the market price received by farmers and the calculated parity price for a product are two different things. Third, there is almost uniform criticism of production control. Few, if any, point out its most glaring weakness; namely, "In most cases it didn't work." If, by controls, the price of corn had been stabilized at a "reasonable" level, perhaps many economic arguments would have been advanced for production controls.

Much could—and probably will be—written on what the editor should have included or omitted. Nothing is to be gained from such a procedure since the volume is already published and wise selections have been made. It is of some concern, however, that so little appeared in the *Readings on Agricultural Policy* on the role that research and education has played in the development of American agriculture. After all, the contribution of our national policy regarding agricultural education and research should not be overlooked.

Some of the articles are a little out of date due to the fact that postwar conditions are somewhat different than anticipated by the writers. The question might be raised if the Association's next step might be to attempt a "policy" book by inviting people to write chapters on definite and assigned topics for a joint publication.

This book, *Readings on Agricultural Policy*, is well worth reading by persons interested in any phase of public policy.

T. K. COWDEN

Michigan State College

The Consumer and the Economic Order, by Warren C. Waite and Ralph Cassady, Jr. New York: McGraw-Hill, 1949. Pp. x, 440. \$4.50.

When this volume first appeared in 1939—a modernized and extended version of Professor Waite's *Economics of Consumption* published in 1928—its reception by reviewers was generally favorable. As a text to service the growing number of college courses which were attempting to approach economics from the consumers' point of view, there was much in the book to recommend it. It was systematic, the mild "welfare" tone offered something of an antidote to the producer oriented curricula of Schools of Business, and there was repeated considerable traditional analysis which students were likely to have missed or to have forgotten from the *Principles* course.

The present edition is not substantially changed. Statistical tables and institutional data have been brought up to date in so far as possible. Reliable information on the world cooperative movements mostly ends with 1939. Chapter VI, "Competition, Monopoly and the Consumer," has been expanded on the basis of the TNEC reports and certain other studies in this area. The over-all length, including the index, has been increased by 51 pages. Here and there the analysis has been tightened up to make space for some of the events that have crowded the last 10 years.

Thus, the virtues of the earlier edition are still present. But so are the shortcomings. And these latter are the more glaring in the light of changes that have taken place, not only in the *real world* but in economic thought as well. In their preface the authors note that, "The ten years that have passed since the first edition of this book have been a period of tremendous change. These changes have emphasized the deep concern of the consumer in the operation of the economic order." Yet, one is scarcely made aware what those changes are. The name of Keynes does not even appear in the index.

While considerable space is devoted to the effect of price changes on consumers, there is practically no mention of changing levels of national income as such. It is certainly very arguable that, despite an inordinate concern over prices and shortages, consumers generally (if such there be) have fared better during these past 10 years than they ever did before in any comparable period, despite the luxury of carrying on a war and supporting a sizeable portion of the European population. There is reason to doubt that, in a return to the "good old days" of low prices, they will fare as well in the next 10, but these doubts are not raised in the present book.

The role of savings is treated only as an aspect of the individual security problem. And on page 412, the following statement appears, "The saved funds are spent as surely as expenditures made by consumers on shoes or flour." Surely, no attempt to treat the "importance of consumers" can lay claim to adequacy if it ignores completely the "new economics." To argue that it is mistaken may be one thing; to act as though it had never happened quite another.

There is a fairly extended treatment of tariffs, but one looks in vain for a reference to FAO, to the employment act of 1946 and its implications—good or bad. Assuming there is no correct answer as to the significance of these matters of more recent concern, ought they not at least be discussed?

Finally, no mention is made of the work of Katona and his associates in the surveys of consumer intentions to spend, of their liquid holdings, and the other basic data being compiled under the sponsorship of the Federal Reserve Board. Even though this work is still in its infancy—having started in 1945—it does offer at the present time some prospect for injecting the fresh air of empiricism into economics, as well as an approach to greater cooperation among the social sciences.

ALVIN E. COONS

Ohio State University

Controlling Factors in Economic Development, Harold G. Moulton. Washington, D. C.: The Brookings Institution, 1949. Pp. viii, 397, \$4.00.

This book is an analysis of "the factors which impede and restrict, and those which generate and promote, economic advancement." Because of the positive conclusions reached and since they represent the mature views of the head of one of the leading institutions of economic research, this study is a major contribution to the literature on economic progress.

Part I is an effort to draw lessons from the past. The remarkable increases in human productivity, population and standards of living since the early part of the 19th century are reviewed. The early classical economists did not foresee such advances because their analysis contemplated diminishing returns from capital with a consequent trend toward a static state. They overlooked two types of developments which have made it an exceedingly dynamic state in which the returns from capital have increased because of their steadily improving efficiency. One development has been improvements in science and technology. Such advances in agriculture, mining, creative chemistry, power, and size of enterprises have been revolutionary in their effect upon productive efficiency. These advances, however, have been facilitated by improvements in economic organization. The corporation, bank credit, and the development of stable fiscal and monetary systems have provided an environment in which free enterprisers could utilize these advances effectively.

Economic expansion, however, has not been unimpeded. It has been irregular partly because of recurring business depressions. The various explanations for these depressions are considered by

the author and the conclusion reached that each cycle has its own peculiarities and that "there is no single cause of economic disorders."

Another restricting factor is the difficulty of maintaining a market for what can be produced. Consumption is limited more by the lop-sided distribution of incomes than by traditional propensities to consume as explained by Keynes. Budget studies show that consumption increases with income though not proportionally. Concentration of income in a small percentage of consumers results in limited consumption for the masses, and high consumption and savings for the few. The rate of savings has not been the governing factor in the rates of capital formation and the output of consumer's goods. The restricting influences rather have been the amounts and distribution of income.

This approach holds no brief for the mature economy conception as developed in the discussions of the Temporary National Economic Committee. If the income pattern is right, consumption will not be held back by any fixed habits. Production will keep pace as consumption expands. The problems of disappearance of frontiers and stagnation of private investment have not materialized.

In Part II the look is forward. The author's first step in considering the future is to set up a series of major economic goals of the American people as follows:

1. A progressively larger total national income
2. A progressively wider division of national income
3. A society in which individual rewards are based primarily on work performed
4. Increasing economic security
5. Greatest possible development of the capacities of every individual
6. Opportunity for every capable individual to earn his own income

A free enterprise system, with the government exercising appropriate regulatory and control functions, is found to be the environment most conducive to achieving these goals. Full development cannot be attained under communism, State socialism, or a hybrid arrangement.

He then raises the question whether so far as natural resources and productive capacity are concerned, the United States within 100 years might support a population double that of the present

on a plane of living eight times as high as the present. Assuming a distribution of income similar to the present, this would involve multiplying expenditures for food and nutrition about eight times, shelter and home maintenance sixteen times, and similar but higher increases for other categories of expenditures. While not inconsistent with past trends, these assumed rates were established somewhat arbitrarily for the sole purpose of testing "the adequacy of basic resources by setting a very high goal." He examines the resources for each category and concludes that *as potentials* they are reasonable.

In the case of food and nutrition, the eight-fold increase involves tripling the food supply and accounting for the balance in improved quality and diversity of foods and higher processing and servicing costs. The tripling of the food supply can be brought about by reclamation, conservation, improvements of varieties and production methods, use of more fertilizers, soil-less food production, and other similar developments. Some agricultural scientists may question the feasibility of tripling the food output in the United States, even though it only involves continuing for 100 years the actual rates of increase during the last 25 years. What may be more startling, however, is his statement that such expansion would not involve diminishing returns.

Certain conditions must prevail, of course, if such potentials are to be realized. (1) Natural resources must be used efficiently. (2) Productivity per man-hour must continue to rise. This involves adequate incentives so that improved technology will be encouraged. (3) Large scale enterprises must be permitted. (4) Monetary and fiscal stability must be maintained. (5) There must be progressive expansion of mass purchasing power.

The latter requirement can be attained most effectively by transmitting the benefits of increasing efficiency through price reductions. This diffuses the benefits to all classes of consumers. If prices are maintained by support programs, wage increases or high profits, the benefits are confined to certain groups. Future markets thus may be narrowed because millions of other consumers actually may suffer a loss in purchasing power. The increasing competition of groups for economic power makes the problem of diffusing purchasing power to the masses more difficult.

The retarding effect of business depressions upon economic progress can be mitigated but not eliminated, in his opinion. A final requirement is peace and international stability. Under such

conditions, economic progress can be achieved throughout the world through the same principles as outlined for the United States.

Few of the ideas and data in this book are new. The basic philosophy was presented in four earlier studies of Brookings Institution: *America's Capacity to Produce*, 1934; *America's Capacity to Consume*, 1934; *The Formation of Capital*, 1935; and *Income and Economic Progress*, 1935. Various points also have been included in other publications of the author and of Brookings Institution. It should be recognized also that some of the findings have been the subject of controversial discussion among economists.

The merit of this book is that it brings together in compact form a well-rounded theory of economic progress, supported by long years of research and study. This experience is reflected also in the clear, forceful style, and logical sequence in the presentation of the material.

R. C. ENGBERG

Farm Credit Administration

Commodity Exchanges and Futures Trading, Julius B. Baer and Olin Glenn Saxon. New York: Harper and Brothers, 1949. Pp. xii, 324. \$5.00.

Following very closely the treatment in *Commodity Exchanges* (Baer and Woodruff, 1935), of which this edition is a revision, the subject of futures markets and exchange operations is broken down into four major categories: historical development, organization and marketing functions, speculation and hedging, and the legal aspects of contracts, clearing houses and the Commodity Exchange Act.

The material relating to the law and organization of commodity exchanges and clearing houses and the discussion of the Commodity Exchange Act is well organized and reflects a first-hand experience of long standing with the technical-legal workings of the exchanges. Throughout the entire book, moreover, the authors have managed to convey their ideas in a simple, almost popular style—a difficult feat to accomplish when applied to such controversial and technical subject-matter.

The handling of the economic aspects of futures market operations perhaps overemphasizes the role of the exchanges insofar as they are presented as being "vital to a free economy"; at the same time, the book underemphasizes the limitations and abuses of futures trading operations. While the authors did not intend to

undertake "an extensive analytical or theoretical treatise . . .", questions relating to the benefits of speculation, the extent of price manipulation and price determination, and similar questions touched on in this book require just such treatment before valid and reliable answers can be obtained. No original analytical contributions have been made by the authors and the scanty quantitative analyses which are presented are based on data referring to pre-War I conditions and, in some cases, to conditions before the turn of the century. No indication is given, moreover, that the authors have considered the statistical data which have become available since 1935 or the more recent advances in economic theory which do not lean so heavily on purely competitive assumptions. This book would have given a more balanced economic presentation had it incorporated the more recent analyses to be found in such publications, among others, as: Blau, G. "Some Aspects of the Theory of Futures Trading," *Review of Economic Studies*, 1944-45; Howell, L. D., "Analysis of Hedging and Other Operations in Grain Futures," United States Department of Agriculture, 1948; Keynes, J. M., "The Policy of Government Storage of Foodstuffs and Raw Materials," *Economic Journal*, 1938; Irwin, H. S., "Middlemen's Accumulations and Expectations in Marketing Farm Products," this *Journal*, 1947; Hoffman, G. W., "Grain Prices and the Futures Market—A Fifteen Year Survey, 1923-1938," United States Department of Agriculture, 1941; and Lerner, A. P., *Economics of Control*, 1946, Chapter 8—"Competitive Speculation." These references in their respective order have been chosen at random to cover one or another point at issue but not discussed as such in the book—the difference between the insurance principle and risk bearing on commodity exchanges, the extent to which hedging is not a perfect risk bearing device, the relation of futures markets to market concentration and accumulation, types of abnormal price and market conditions, and the concept of counter-speculation.

While a descriptive treatment of the existing institutional workings of the exchanges does not necessarily require it, the economic analysis would be more meaningful if some consideration had been given to a comparison of the relative merits of the integrated firm, various systems of forward pricing, and other alternatives to the futures markets as a means of transferring or reducing risks in the marketing of agricultural commodities.

HERMAN L. MYERS

Bureau of Agricultural Economics

Agriculture and Industrialization: The Adjustments That Take Place as an Agricultural Country Is Industrialized, Pei-kang Chang.
Cambridge: Harvard University Press, 1949. Pp. xiv, 270. \$5.00

In this book the author, Professor of economics at Wuhan University, seeks to examine the theoretical, empirical and historical aspects of "the adjustments between agriculture and industry during the process of industrialization" with particular attention to the adjustments within agriculture itself (p. 1). At the outset he proposes four questions for special study: (1) Is industrial development a necessary or a sufficient condition for agricultural reform in a densely populated rural region, or *vice versa*? (2) Is it possible to maintain a balance between agriculture and industry within a given country? (3) Is it possible to maintain harmonies and mutually beneficial relations between countries primarily agricultural and those essentially industrial? (4) What are the particularly pressing problems which would most probably confront an agricultural country during its process of industrialization?

In answering these highly important and ambitious questions within the rather modest length of this book, Professor Chang's principal contribution proves to be largely that of summarizing and synthesizing the many-sided literature of the field. His bibliography is extensive and will be helpful to all who are interested in problems of industrialization and economic progress. He makes clear that so broad an analysis must depend upon the whole gamut of economic theory—general- and partial-equilibrium, imperfect competition, location, production, national income, business cycles, capitalist development, and interregional and international trade. That he is able to review rather satisfactorily so great a range of theoretical literature and to indicate, in each case, its relevance to his problem is an impressive demonstration of his comprehensive economic training and his professional versatility. However, the over-all result is unfortunately an excess of superficiality and pedantry. For example, is it still necessary to define at length such concepts as the price and income elasticities of demand and the elasticity of substitution (pp. 30-36 and 131)? The theoretical and empirical parts of the book—neither of which demonstrates much originality on the author's part—are not very well integrated. The empirical data, for the most part, will be familiar to most American readers, either because they describe well-known trends within the United States or because they are from such standard international sources as Colin Clark's investigations.

Several errors might be noted. The first footnote on Page 66 incorrectly expresses the mathematical forms of the "Cobb-Douglas formula." On Page 120 (line 9 et seq.) the analysis of the initial effects of a technological improvement upon the perfectly-competitive firms first adopting it (Fig. 3) is wrong in supposing that these firms' sales would be limited to the old equilibrium volume OA. Instead, taking the new (lower) marginal-cost curve into account, their output would for a time exceed even the new long-run equilibrium volume OB. Finally, it surely cannot be true (pp. 211-12) that "... the prices of the [Danish] exports of agricultural products have been relatively unaffected by cyclical fluctuations of business. . . ."

The most original and interesting part of Professor Chang's book is Chapter VI, in which he briefly applies his analysis to Chinese industrialization. Having now clearly shown his broad knowledge of the general theoretical and empirical literature of his field, Professor Chang should be encouraged to devote his future research efforts to an expansion of his investigations of the problems of industrializing his own important country. Economists throughout the world would await his findings in this area with great interest and anticipation.

WILLIAM H. NICHOLLS

Vanderbilt University

The Economic Problems of Forestry in the Appalachian Region,
William A. Duerr. Cambridge: Harvard University Press, 1949.
Pp. x, 308. \$5 00.

The five states of Kentucky, North Carolina, Tennessee, Virginia and West Virginia are chosen to represent the Appalachian Region. The total area included in these five states is then subdivided into five "physiographic" provinces as follows: (1) Coastal Plain, (2) Piedmont, (3) Highlands, (4) Great Valley and (5) Interior province. The author also calls these provinces "forestry" provinces, "not because they have been delineated with special reference to the forestry situation, but because they are believed to conform in general to the broad geographic pattern of forestry conditions in the region and will be used in describing and analyzing these conditions."

The first chapter of the book contains a scholarly discussion of many economic and social data summarized according to the above-

named forest provinces. Anyone interested in this arrangement of data will find this chapter helpful.

The second chapter deals with problems of people and the land, with special emphasis on the people of the Highlands and the Piedmont. More use is made of state data. The significance of custom and tradition is emphasized.

The third chapter is concerned with problems of forest-land management such as ownership, tax-delinquency, taxation, fire, etc. The fourth chapter discusses timber management practices and the economic characteristics of timber as a crop.

The next five chapters are devoted to marketing problems. In the opinion of this reviewer, the most interesting chapter in the book is Chapter VII, which describes problems in marketing pulpwood. The discussion of the "contractor system" and its abuses reads like the work of one who knows what he is writing about.

The book ends with a chapter on the consumption of forest products in which a plan for the consumption of forest products is identified with a plan for harvesting. Estimates of growth and drain of timber are given. The key idea that gives form to this chapter is the notion that "It is necessary to compare consumption, not with standing timber, but with the ideal consumption under some rational plan, before it can be ascertained whether problems exist." A balance between growth and drain seems to be the ideal or rational plan.

Among the many ideas the reader will get from this book, two are especially significant: (1) the large percentage of total forest products represented by fuel wood, and (2) the preponderance of farm and other small private holdings of forest land.

As the story unfolds, the use made of the physiographic or forest provinces becomes progressively less; and unless one has read the preface and the 27 pages of introductory material, he might begin to wonder whether the purpose of the volume was merely to discuss the economic problems of forestry in the Appalachian region as the title suggests.

Much of this introductory material undoubtedly helped the author in his very practical problem of working out requirements for the Ph.D. at Harvard, but so far as the public is concerned the book would have been much better if it had begun with Chapter I and had omitted all the confusion about the definition of economics and the field of forest economics. The hedonistic or pleasure-pain

conception of economics is only one view; and the notion of economics as a "link between things and people" rather than as relations between people and people leaves much to be desired. Just why engineering is classed as a "naturalistic" science is left unexplained.

If the book is to be regarded as "a definition of forestry economics" rather than mainly as a discussion of some of the economic problems of private forestry in the Appalachian region, the author has given too little attention to the public economics of forestry. Although public forestry is mentioned, and even though it is conceded that public and private interests in forest land management may not always be in harmony, little use is made of these observations to give public ownership and management of forest lands, as well as public regulation of privately owned forests an increasingly important place in a "rational plan."

Various passages in the book show the author to be no blind devotee of rampant free enterprise, but he has not given sufficient emphasis to the fact that forestry economics includes public action to deal with the anti-social consequences of forest land ownership in fee simple—consequences he clearly recognized.

BUSHROD W. ALLIN

Bureau of Agricultural Economics

The United States International Timber Trade in the Pacific Area,
Ivan M. Elchibegoff. Stanford: Stanford University Press,
1949. Pp. xvii, 302. \$7.50.

At this stage in world history when the United States is shifting into a dominant international role, and our foreign trade position is a matter of great importance, exports and imports of timber take on a new significance; particularly when our supplies of exportable timber are shrinking and dollar-short nations hope to pay for some of their purchases here with raw or semi-manufactured forest products. Dr. I. M. Elchibegoff's contribution on timber trade in the Pacific is particularly timely.

Although timber has not been a large part of the Pacific foreign trade in terms of dollar value (14.3 percent), it is significant that slightly more than 50 percent of the shipping space in 1936 was utilized by forest products. The author points out further that the 26 countries in the Pacific area exported a total of 3.8 billion board feet of logs and lumber while importing 2.9 billion feet. A surplus

for shipment outside of the Pacific zone was thus made available.

This book is divided into three parts, the first of which deals with introductory material and definitions. Trade terminology and the classes of woods are discussed in terms of supply and demand by each nation in the Pacific area. Significance of the timber trade in relation to all world trade is treated in considerable detail.

Part Two deals with the forest resources both in terms of supply and past production of each of the 26 forested nations bordering the Pacific. Separate chapters complete with tables, not only cover the forest areas and resulting products therefrom, but also population and agricultural statistics. Maps showing the distribution of each forest area are included. Dr. Elchibegoff has drawn his data from all readily available sources—much of which is especially sketchy because adequate forest inventories have never been undertaken; or they are incomplete and partially available. Some are held in secret. The author has brought together under one cover some very revealing data on the Pacific forests of the U.S.S.R. as well as Manchuria. This volume will serve as a ready reference on the forest statistics for all countries bordering the Pacific along with such material as is presently available through FAO. A useful addition would be a general map of the Pacific area as a means of orienting the reader to the individual maps shown for each nation.

A great many tables covering population, crop production, land use, etc. are included both in Part Two and in the Appendix. Other than the fact that these serve as a basis for determining available labor supply and internal consumption of forest products, their significance to foreign trade is not made entirely clear. So much of this sort of material is included as to obscure the really important facts which can be gained from the population-resource ratios.

In Part Three the author undertakes to analyze and assess the implication of each nation's foreign trade policies and economic factors influencing trade. Technical trends in wood uses come in for examination, particularly in relation to the pulp and paper industry of the United States and Japan. Production costs, prices and transportation factors in the United States are treated descriptively, but unfortunately very little comparable data have been presented for other nations. In the case of tariff policies and their effect on the volume of import and export trade, better comparisons are presented for the major trading countries. For example, the disastrous effect of the Hawley-Smoot Act of 1930 on United,

States West Coast lumber exports is demonstrated in the greater than proportional drop in volume which the Reciprocal Trade Agreements failed to restore.

Since the beginning of World War II the United States has been a net importer of lumber—a drastic shift in our historical position. Unfortunately, the author fails to probe this situation in the detail it warrants, particularly since stumpage supplies available for future export are no longer abundant. The West Coast of the United States has always consumed a large quantity of imported tropical hardwoods. With an increasing shortage of high grade North American furniture woods the opportunities for greater importation from the tropics are opening up. Peeler logs used by the West Coast plywood industry are likewise in short supply due to timber depletion. Opportunities for importation of large tropical logs for this purpose are present, and one wishes the author had placed more emphasis on these shifts which are already in the wind.

Except for a few technical errors this volume can be criticized principally for its limited scope rather than content itself. One looks in vain for some treatment of the structure and institutions actually performing the foreign trade in timber products. Answers to such questions as profit margins or brokerage commissions and distribution and uses of product are not treated. Although the author treats most of the Pacific countries in as great detail as data permits, huge forest areas such as New Guinea and the large island groups of the South Pacific are not covered.

Perhaps too much emphasis is given to the fact that the United States has been an exporter of softwood lumber in the past. Development of new chemically derived products from wood in addition to paper is in the offing and it is conceivable that this may become a far more important item than it is possible to forecast at present. Nevertheless, lumber requirements both for repair of war damage and improving housing standards will comprise the great bulk of demand for timber in the foreseeable future, as the author points out.

Several minor technical errors in the use of the term "sulfite" in place of "sulfate" (p. 194) and *vice versa* on page 198 change considerably the implication of the author's forecasts in relation to the Southern and Alaskan pulp industries. This reviewer finds it difficult to believe that plant expansion in these two regions will supplant imports of duty-free Canadian newsprint. The power

of the press will continue to be exerted in behalf of duty-free imported newsprint in the future as it has in the past. Nowhere in the Continental United States and only in limited Alaskan areas is it possible to find the combination of spruce and abundant water power needed to make a large expansion in newsprint production. Canada holds the key to this situation.

Although the author has carefully stayed within the limits of the traditional pattern of foreign trade as it has been carried on within the past, a very useful purpose would be served if he had indulged in some quantitative forecasting. Two factors which are already beginning to show themselves could change foreign trade relationships considerably. Political stability in China under almost any conceivable regime will very probably result in a very slight improvement in living standards, if only because less energy is spent in war. This slight rise would reflect itself in an increased demand for housing and hence lumber of very large proportions.

The other unknown, of course, is Russia's entry into foreign trade on a much larger scale than at present. Elchibegoff's data on Russian Pacific timber supplies show some very large quantities available. If these are made available to the world market very considerable shifts in past trade trends would take place. Both of these prognostications depend upon shifting political winds which are very difficult to forecast. Yet the large potential demand and supply areas can be measured quantitatively and their effect evaluated if they should become active participants in foreign trade. Although prognostications of this nature could never be made with any degree of finality they would serve the useful purpose of preparing policy-makers with a set of alternatives which could develop in the future. It would thus enable the United States and other nations in the world to adapt themselves to the various eventualities which actually will develop.

Elchibegoff has made a useful contribution to forest economics literature. He has assembled material from nearly every available source and focussed it into an important trade area. Since forestry literature is almost wholly lacking in texts on foreign trade in forest products, this book will be welcomed as a distinct contribution to the field and will find considerable demand by students, teachers, economists and persons engaged in international trade.

CHARLES H. STODDARD

509 Lyceum Building, Duluth, Minn.

Theories of Welfare Economics, Hla Myint. Cambridge: Harvard University Press (for the London School of Economics and Political Science), 1948. Pp. xiv, 240. \$4.00.

This book does more than its title suggests. It contains both a clear, concise summary of modern welfare economics and a refreshingly accurate interpretation of classical economics. It is a history of economic thought that rightly devotes more than half its pages to the period since John Stuart Mill. It defines welfare economics at once so broadly as to include the main body of all economic theory, and so narrowly as to exclude (because it involves unscientific interpersonal comparisons of utility) the problem of the distribution of personal incomes. The book is a critical summary of each major theoretical system that deals with increasing welfare through production and exchange.

In Part I, "Physical Level," Professor Myint views the classical writers. Their primary concern was not the allocation of given resources (this view is a "theoretical anthropomorphism" of the modern day), but increasing the total physical output by raising the physical productivity of labor and expanding the total volume of economic activity. Hence their dynamic laws of population and capital accumulation. Free Competition was intended to promote dynamic expansion by giving free rein to individual initiative (quite different from today's pure and perfect competition, intended to secure allocative efficiency).

The great controversy between Malthus and the Ricardians over the balance of production and consumption here assumes its rightful place. Professor Myint has a brilliant analysis of the measure of value problem. This neglected element in classical economics was an integral part of the Glut controversy. Keynes' measurement of the national income in wage-units is, after all, the equivalent of Malthus' use of labor commanded. Second only to this as a specific contribution is his sympathetic interpretation of Productive Labour.

On details of interpretation there are bound to be differences of opinion. Not seeking a typical case, let me pause with Malthus. Professor Myint's generally excellent treatment is based on the second edition of Malthus' *Principles*. Reference to the first edition would have shown that Malthus' use of the intensity of demand was independent of (and prior to) Senior's "path-breaking work" on marginal utility (cf. Myint, p. 36). Furthermore, Malthus' *Measure*

of *Value* (1823) shows that the distinction between "extrinsic" and "intrinsic" value was not borrowed from Senior. Only the labels were borrowed (*cf.* Myint, p. 38). Again, Malthus' emphasis on the "intensity of demand" did not reduce entirely to purchasing power, for he stressed the *will* as well as the power to purchase, and emphasized that the maintenance of effective demand required that the commodities produced be suited to the tastes of consumers (*cf.* Myint, pp. 37-38, 64).

Part II, "Subjective Level," concerns the marginalist writers. Allocation of resources, in the full sense of adaptation of products to consumers' wants, is now the dominant theme. Diminishing marginal utility or substitutability replaces the assumption that quantities of welfare are roughly proportional to quantities of physical products, while given resources are assumed rather than augmentable ones.

There are excellent brief summaries of the General Equilibrium school, with their general optimum defined in terms of equality between subjective and technical marginal rates of substitution, and the English Neo-classical school, with their stress on exceptions to the principle of competition and their techniques of surplus analysis and comparison of marginal social product with marginal private product. Each type of analysis has its place, Professor Myint feels, but the surplus analysis promises most for practical use.

Part III, "Ethical Level," considers those criticisms of conventional theory that object to its assumption of constant wants. Yet conventional theory remains useful, Professor Myint believes: consumers' demand is relatively stable at any given moment of time and scientific impartiality must be sought. However, the broader problems of general social welfare on the ethical level cannot be ignored. We must make value judgments when dealing with practical social policy, but we should do it consciously and deliberately.

VICTOR E. SMITH

Michigan State College

Grass Silage and Dairying, Ray W. Ingham in Association with Willis A. King, Walter C. Russell and Carl B. Bender, New Brunswick, Rutgers University Press, 1949. Pp. vii, 88.

The New Jersey Agricultural Experiment Station has been one

of the pioneers in grass silage research, especially in its chemical and engineering aspects, since the early 30's. The brief volume under review covers, among other things, the results of a five-year feeding study carried out by the Station with partial support from the Herman Frasch Foundation for Chemical Research. It purports to present to "the less specialized reader" a "clear and balanced picture of the nutrient values of the more familiar grass silages and the effects of those silages on the milking cow and her output."

It does present some useful data on feeding value, and physiological effects of silages of (1) molasses-alfalfa vs. phosphoric acid-alfalfa, (2) molasses-oats vs. phosphoric acid-oats, (3) molasses-soybean vs. corn meal-soy bean, (4) molasses-grass vs. ground barley-timothy, (5) molasses-timothy vs. ground barley-timothy. In all of these tests cows were matched for productive ability, and corn silage was used as the control.

The authors follow a line of reasoning apparently designed to prove that dairy farmers throughout the humid part of the country should put up grass silage, and preserve it with molasses. Barn drying is dismissed with a single sentence: "Although in mow cured hay they [nutrient losses] are much less, the cost of special equipment . . . can be prohibitive." (p. 17)

Corn meal used as a preservative, while showing up well in production is not favored because "... ground grains are expensive in some sections, especially when, as is often the case, they must be applied at the rate of from 200 to 250 pounds to the ton." (p. 64) Value of nutrients added is not mentioned.

Field wilting is eliminated because "'65 per cent' of included moisture is extremely difficult to gauge. Only the most experienced operator can be reasonably certain that the crop has dried just that far and no farther." The reviewer was not aware that good results by the wilting method required exactly 65 per cent moisture; he is under the impression that about 60 to 68 per cent is the permissible or optimum moisture content. A recent survey indicates that about 85 per cent of Wisconsin farmers who wilted their grass silage and did not use a preservative produced "good" or "excellent" silage.

It is unfortunate that the comparative cost data given includes nothing on field forage harvesters. There is good reason to doubt whether, without a bigger cost advantage in favor of grass silage than appears to exist, the practice of ensiling grasses by stationary

chopper will ever become general. There are too many headaches and backaches.

This small volume is already out of date as a result of the rapid adoption of the field forage harvester and the "wilting method" of making grass silage.

EDWARD J. SMITH

University of Wisconsin

NOTE TO THE MEMBERSHIP

In order to keep expenditures in line with income the Executive Committee instructed the Editor to limit the Proceedings (Part II of this issue) to 400 pages and the total size of the annual volume including four regular issues and one Proceedings Supplement to 1200 pages.

Papers at the Laramie meetings have been shortened considerably, yet the Proceedings are in excess of the limit set. Authors have been most cooperative.

The editor requests that you review the Proceedings in some detail and comment on the following:

1. Should the printing of full length papers be limited to those presented at the general meetings with only a digest printed of the papers and discussion at each of the sectional meetings?
2. Should dues be raised and all the material presented at the annual meetings be printed?
3. Should the same procedure be followed next year with more severe cutting, or should authors be given rigid limits at the time they are invited to prepare papers?

NEWS NOTES

T. A. Adams, University of Vermont, was elected President, and J. L. Tennant, Rhode Island State College, Secretary of the New England Institute of Cooperation at the annual meeting, June, 1949.

C. E. Allred, University of Tennessee, has been elected Chairman of the Marketing Section, Association of Southern Agricultural Workers.

George H. Aull, Clemson College, L. P. Gabbard, Texas A. & M. College and J. F. Timmons, Iowa State College were U. S. Delegates to the recent United Nations Scientific Conference on the Conservation and Utilization of Resources, Lake Success.

R. C. Ashby, who has completed 23 years of service at the University of Illinois, has retired. He has accepted a position in the livestock marketing field at Morningside College, Sioux City, Iowa.

Kenneth L. Bachman, Division of Farm Management and Costs, BAE, was made chairman of a Commission of specialists organized by the Army to visit the Ryukyu Islands and report on their potential production. The party left September 14 and expected to work for about two months.

Merton B. Badenhop returned to the Agricultural Economics staff at the University of Tennessee, July 1, after having spent a year in graduate study at Purdue.

Ralph L. Baker, who recently received his Ph.D. in poultry marketing, has been promoted to Associate Professor in economics at Iowa State College.

W. L. Barr has completed his Ph.D. at Cornell and returned to his position as Associate Professor of farm management at Pennsylvania State College.

Russell L. Berry has been appointed Assistant Professor, Agricultural Economics, South Dakota State College. He will do farm management research and teaching.

Warren Bilkey has been appointed Assistant Professor at the University of Connecticut.

Robert Branson, on leave from BAE is making a study of food marketing problems in Puerto Rico.

Ronald Bird joined the staff of the Department of Agricultural Economics, West Virginia, as a joint employee with the Bureau of Agricultural Economics and is engaged in egg marketing research.

Ayres Brinser, recently Economist with the Federal Reserve Bank of Boston, has been appointed Research Associate on a study of wartime rationing under the direction of Dr. Galbraith, Harvard.

Lauren H. Brown has returned to Michigan State College after a year of work with the Halderman Farm Management Service.

Daniel W. Burch has joined the Division of Agricultural Finance of BAE to work in the field of farm taxation and local government.

Glenn L. Burrows, who has been working under Hotelling at the University of North Carolina on research in multi-variant analysis, has been appointed statistical consultant for BAE to work on special problems of mathematical statistics.

Alvin G. Carpenter, Utah State Agricultural College, has been granted a leave of absence for a year for graduate study at Cornell.

Albert Conley has accepted an appointment as Associate Professor of Agricultural Economics, University of Missouri. He fills the vacancy created when Dr. E. H. Matzen accepted an appointment with the Farm Credit Administration, Washington.

Samuel L. Crockett has transferred from the Division of Land Economics, BAE, to the Loan and Purchase Division, PMA.

Samuel A. Dum joined the Agricultural Economics staff at the University of Delaware July 1, 1949 after completing his doctorate at Purdue.

Worley S. Earp and Ocie Coston have transferred from the Division of Statistical and Historical Research, BAE, to the Cotton Branch of the PMA.

Harold H. Ellis has joined the Washington staff of the Division of Land Economics, BAE. He will work on the legal aspects of land tenure.

Ernest Feder has been appointed Assistant Economist and Assistant Professor, Agricultural Economics, South Dakota State College.

V. B. Fielder, Associate Professor, University of Arkansas, taught a graduate course in Land Economics during summer school at the Agricultural Mechanical and Normal College, Pine Bluff, Arkansas.

G. W. Forster, Head of the Department of Agricultural Economics at North Carolina State College since September, 1923 will devote full time to research and teaching, effective April 1, 1950. Professor H. Brooks James, a member of the staff, has been selected as his successor. At present Professor James has been granted a six months' leave of absence to study work in agricultural economics now under way at leading institutions of the nation.

Lowell N. George, formerly at the University of Illinois, has been made head of the Department of Economics and Business Administration at Muskingum College, New Concord, Ohio.

James R. Gray has joined the Division of Farm Management and Costs, BAE, after a year of graduate work at Utah State Agricultural College, to carry on the study of family operated cattle and sheep ranches in the Northern Great Plains. Arthur Roth, who has been engaged in that study for more than a year resigned to enter private employment October 1.

Among those doing graduate work at Harvard University this year are: William Drummond, Head of the Department of Agricultural Economics at Ontario Agricultural College; Director R. B. Tootell, State Agricultural Extension Service of Montana; Miss Maurine Hearn, Director of Women's Extension Work, Texas; W. N. Williamson, District Extension Supervisor, Lubbock, Texas; W. A. Henry, University of Connecticut; Glen Barton, Maxwell Klayman and J. W. Birkhead, on leave from BAE; John Blackmore, on leave from TVA; Dorris Brown, University of Missouri; John Sharp, University of Tennessee, and M. N. Williamson, Texas A. & M.

Earl O. Heady has been promoted to full professor at Iowa State College.

William F. Henry of the University of Connecticut has been granted a leave of absence for advanced study at Harvard.

T. A. Hieronymus has been promoted to Assistant Professor in Agricultural Economics, University of Illinois.

E. B. Hill, Michigan State College, will spend the fall term working with the North Central Land Tenure Committee and the Farm Foundation. He and Marshall Harris will be preparing a regional manuscript on father-son farm partnerships and succession in farming.

Leo M. Hoover is on leave of absence from Kansas State College working at Harvard University on the Ferguson Foundation research project in farm labor.

R. R. Hudelson, Associate Dean, College of Agriculture, University of Illinois, accepted a summer assignment in an agricultural advisory capacity in the British zone in Germany.

Charles D. Hyson has accepted a post as Economist for the ECA and will be stationed at Oslo, Norway.

H. B. James, North Carolina State College, taught a course in Farm management as a visiting professor at the University of Arkansas during summer school.

Hugh A. Johnson left the BAE Division of Farm Management and Costs in June to head up economic research work in Alaska and is now stationed at Palmer.

Lloyd E. Jones has transferred from the Division of Farm Management and Costs, BAE, to the Underwriting Division, Federal Crop Insurance Corporation, Washington, D. C.

W. E. Koepper returned to his duties as Professor of Agricultural Economics, Pennsylvania State College July 1. During the last year he has worked on coffee farm management research in Costa Rica and Colombia.

Karl S. Landstrom, formerly Agricultural Economist, BAE, Portland, Oregon, is now Chief of the Division of Land Planning, Region I, Bureau of Land Management, with headquarters at Portland.

Donald Larimore, a graduate student at Harvard University during the past three years, has accepted an appointment as Economist with the ECA and will be stationed at the Paris office.

Adrian H. Lindsey was granted a leave of absence from the University of Massachusetts for the Spring semester of 1949 and spent it in study at the Giannini Foundation of Agricultural Economics, University of California.

Milton L. Manuel has been appointed Associate Professor of Cooperative Marketing, Kansas State College. He has been doing graduate work at the University of Minnesota.

H. J. Meenen has accepted a position as Assistant Professor, Department of Rural Economics, University of Arkansas.

Frank Miller of the University of Nebraska has joined the staff of the Agricultural Economics Department at the University of Missouri as Professor of Agricultural Economics to work in the field of Land Economics. Dr. Miller is taking the vacancy created when Dr. C. H. Hammar resigned to work in the Food and Agriculture section of the Army of Occupation in Germany.

Alexander J. Morin has accepted a position as Chairman of the Department of Economics and Business Administration at Fisk University, Nashville.

William Morgan, formerly of Texas A & M, recently in the Paris office of ECA, became President of Colorado A & M on Oct. 1.

M. L. Mosher, University of Illinois, was given special recognition by the U.S.D.A. for his long service and contributions to the field of farm management.

Mardy Myers has transferred from the PMA to the Division of Statistical and Historical Research of BAE. He will conduct research on dairy marketing.

Samuel Myers has been appointed to the post of Research Associate at Harvard to carry on research under the RMA contract.

W. D. Nicholls, University of Kentucky, recently spent four weeks in England making an intensive study of the English farming setup and management. These studies were made possible by arrangements with the English National Farmers Union of which 95 percent of all farm operators are members.

L. J. Norton, University of Illinois, is on sabbatical leave the first semester and will spend most of his time in Europe. He will make a study of fat and oil demand in cooperation with the Office of Foreign Agricultural Relations.

Russell O. Olson, South Dakota State College, is on leave of absence to pursue graduate study at Iowa State College.

A. L. Owens, Rhode Island State College, returned to his duties September 1, following a year's leave for study at the University of Illinois.

Walter W. Pawson has transferred from the Bureau of Reclamation, Department of the Interior, to work on the economics of conservation in the Northwest as a member of the Division of Farm Management and Costs, BAE, with headquarters at Portland, Ore.

Weber H. Peterson, Clemson College, was a visiting professor at the University of Arkansas during the second session of summer school.

C. W. Pierce while on sabbatical leave from Pennsylvania State College will serve as regional coordinator for the southern regional dairy marketing research project, State College, Mississippi. During the summer Dr. Pierce taught at Cornell after which he attended the Conference of Agricultural Economists at Rome.

Homer J. Preston, who will complete his Ph.D. at Pennsylvania State College in February, has accepted a position with the Cooperative Research and Service Division, FCA.

Mrs. Barbara Reagan, Research Associate, Harvard, has been appointed to the Bureau of Nutrition and Home Economics to assume responsibility for research in levels of living.

Sidney Reagan, at Harvard University on leave from his post as Economist for FHA for the past two years, has been appointed Economist for the PMA to make analyses of fats and oils problems.

Rex Rehnberg joined the Agricultural Economics staff at the University of Arizona September, 1949, after completing his Ph.D. at Purdue.

Thomas C. M. Robinson, who has headed the Farm Employment Section, BAE, for the past three years, has transferred to the State Department as Agricultural Attache in the American Embassy in Canberra, Australia.

George Rockwell has joined the Division of Statistical and Historical Research, BAE, to conduct research on tobacco marketing.

George B. Rogers of the Division of Statistical and Historical Research BAE, has returned from France where he was a member of the United States delegation to Third Session of Contracting Parties General Agreement on Tariffs and Trade.

Anthony Rojko has joined the Division of Statistical and Historical Research. Mr. Rojko was formerly a Marketing Research Agent with the New England Research Council.

Charles F. Sarle, U.S.D.A., is in Turkey making a study of that country's statistical needs. The project, sponsored by the Economic Cooperation Administration, was requested by the Turkish government.

Richard G. Schmitt, Jr., formerly with BAE, Division of Agricultural Finance, has joined the staff of the Rural Electrification Administration in the program analysis section.

O. J. Scoville, BAE, Kansas State College, has been designated regional technical assistant to the sub-committee on soil conservation of the North Central Farm Management Research Committee.

Stanley K. Seaver has returned to the University of Connecticut after a year's sabbatic leave spent at the University of Chicago.

Roy E. Speck, formerly with the Texsun Citrus Exchange and graduate of the University of Texas, has recently joined the staff of the Dried Fruit Division, Fruit and Vegetable Branch, Production and Marketing Administration, U.S.D.A.

Leland Spencer sailed for Europe July 12 to attend the International Dairy Congress in Stockholm, Sweden, and International Conference of Agricultural Economists at Stresa, Italy. Professor Spencer will visit several countries in western Europe where he will study economic conditions in the dairy industry and recent developments in the marketing of fluid milk.

Don Stark returned to the staff of Agricultural Economics at Michigan State College as Extension Specialist in Livestock Marketing on July 1. He has been on leave of absence for one year working with the Detroit Packing Company, a farmers' cooperative company.

Delwin M. Stevens has been appointed Associate Professor of Agricultural Economics, Colorado A & M. He has been doing graduate work on his Ph.D. at the University of Minnesota.

Hugh L. Stewart is now Assistant Head of the Division of Farm Management and Costs, Bureau of Agricultural Economics. He succeeds Neil W. Johnson who became Special Assistant to the Administrator, Agricultural Research Administration, in March 1948.

H. R. Stucky, Extension Specialist in agricultural economics for the Montana Agricultural Extension Service, has just completed a quarter's leave of absence, during which time he has been at the University of Minnesota for advanced study.

Alonzo E. Taylor, director emeritus of the Food Research Institute of Stanford University, died on May 20, 1949, at the age of 78 after a brief illness. Dr. Taylor was one of the founders of the Food Research Institute

and a director from 1921 to 1936. After his retirement he was associated with General Mills, Inc., first as director of research, then as consultant, until 1945. Dr. Taylor was a member of the American War Trade Board in 1917-1919, professor of pathology and physiological chemistry at the University of California from 1899 to 1910, and was Rush professor of physiological chemistry at the University of Pennsylvania from 1910 to 1921. He was the author of several books on food chemistry and human nutrition, papers in research and popular science, and *Corn and Hog Surplus of the Corn Belt* (1932), and *The New Deal and Foreign Trade* (1935).

The Tennessee Agricultural Experiment Station is cooperating with the Mississippi Station on a study of milk marketing in the Memphis milkshed. The Tennessee Station is also cooperating with the Federal Bureau of Agricultural Economics on a study of costs and margins of milk distributors in the Memphis area.

Tennessee and Kentucky Experiment Stations are making a joint study of both the Eastern and Western dark tobacco growers associations.

The Tennessee Agricultural Experiment Station is cooperating with the Production and Marketing Administration, U.S.D.A., in making a study of hedging practices of feed mills in the Southeast.

Tennessee University students majoring in Agricultural Economics have formed a club and will apply for a charter as a student subsidiary of the American Farm Economic Association.

Phil J. Thair has accepted an appointment with the Bureau of Agricultural Economics. He is stationed at the North Dakota Agricultural College, and is in charge of a comprehensive research project on risk, uncertainty and problems of income stabilization in the Great Plains farm economy. This project is carried on jointly by the North Dakota Agricultural Experiment Station and the Bureau of Agricultural Economics.

Gerhard Tintner has returned to Iowa State College after a year's leave of absence in Europe, during which he spent one year in research at the Department of Applied Economics, Cambridge, England. He also taught econometrics at the University of Cambridge and gave lectures at the universities of Dublin, Uppsala, Paris, Bristol, Oxford, Manchester and Hague.

Durward B. Varner joined the staff in Agricultural Economics at Michigan State College on May 10. Mr. Varner has spent the last three years as a student at the University of Chicago and is a pre-war graduate of Texas A and M. At Michigan State College he will participate in the Extension project in market price analysis and public policy in agriculture.

Warren H. Vincent, formerly instructor in Farm Management at Michigan State College, was transferred on May 1 to the position of Extension Specialist in Farm Management (Assistant Professor). Mr. Vincent obtained his Master's degree in Farm Management at Michigan State College in June 1949.

Stanley W. Voelker, Land Economics Division, BAE, has transferred from Fort Collins, Colorado, to North Dakota Agricultural College, Fargo, where he will be working on problems in land and irrigation economics in connection with the Missouri Basin Development research program.

Malcolm E. Wallace, formerly of North Carolina State College, has joined the Agricultural Finance Division of BAE to work in the field of short-term credit.

Arthur J. Walrath has returned to the Division of Land Economics, BAE, after two years with the Department of Agricultural Economics at New Mexico A & M. He will be stationed at Portland, Ore.

Thomas J. Whatley is on leave of absence from the University of Tennessee, studying for his doctorate in Agricultural Economics at Purdue.

Norman V. Whitehair has been appointed Assistant Professor at Kansas State College. He will do extension work in grain marketing.

C. P. Wilson has been granted a leave of absence from Kansas State College to do graduate work at the University of California. Harold Riley will assume Professor Wilson's work in livestock marketing.

Harry S. Wilt has recently been appointed as Assistant Professor in research in Farm Management at Michigan State College. Mr. Wilt has been on the Short Course staff at Michigan State for ten years and has assisted in teaching farm management to students enrolled in the short courses.

Karl T. Wright of Michigan State College has just returned from two months in Europe. He visited ten countries collecting information on the economic aspects of forage production and attended the International Conference of Agricultural Economists at Stresa, Italy.

H. J. Wyngarden, Head of the Economics Department, Michigan State College, since 1943, became Dean of the School of Business and Public Service, July 1, 1949, replacing Dean D. R. Rodney, who has reached retirement age. Charles C. Killingworth will replace Dr. Wyngarden as Head of the Department of Economics.

The American Institute of Cooperation has available an outline for a graduate course in agricultural cooperation which was developed at a workshop this summer preceding the Institute session at the University of Wisconsin, Madison. Also available is the report of the workshop for Extension workers.

No. 4, Part 2

OUR AMAZING POPULATION UPSURGE

JOSEPH S. DAVIS

Food Research Institute, Stanford University

THERE is real truth in de Tocqueville's old footnote: "The population of a country assuredly constitutes the first element of its wealth."¹ Though I am skeptical of all forms of fundamentalism, I hold that our most basic national resource is our people.

This week the Census Bureau released its population estimates for July 1, 1949, unadjusted for underenumeration of children in 1940. If we add to this figure, 149,215,000, the official estimate of the required adjustment, 863,000, our "true population" slightly exceeds 150 million, which some textbooks now in use still mention as our probable peak for all time. We may confidently expect the true population on July 1, 1950 to be around 152 million, roughly double that of July 1, 1900.

If the latest official postcensal *estimates* can be fairly trusted, the population of the continental United States (including armed forces overseas) increased in the decade ending July 1, 1949 by 18.3 million, or 14.0 percent.² The corresponding increase in the decade ending July 1, 1950 will surely be larger, in round figures probably at least 19 million, or 14.4 percent.³ This is more than double the absolute increase in the decade ending July 1, 1940 (now estimated at 8,893,000), and double the rate of increase in that

¹ Alexis de Tocqueville, *Democracy in America* (Aldine ed., Appleton, New York, 1899), II, 465. The Second Part, in which this footnote appears, was originally published in 1840.

² Recent monthly figures are given in Bur. Census, *Current Population Reports: Population Estimates*, Series P-25, No. 27, Aug. 19, 1949.

Such figures are based on the best data available on births and deaths, with skilled allowances for under-registration, and on carefully scanned data on in- and out-migration. Though subject to revision after the next census enumeration, as of Apr. 1, 1950, the revisions can hardly be so drastic as to affect the substance of this paper.

³ A UP release of July 31, 1949 on the Census Bureau gave this figure as the officially "expected" increase. *New York Times*, Aug. 1, 1949, p. 20.

prewar decade (7.2 percent). Contrary to confident expectations of a sharp decline in the population increase after the anticipated postwar upsurge of births, the latest reported 12-months net increase (to July 1, 1949), officially estimated at 2,644,000, is only seven percent below the all-time record figure of 2,845,000 in the 12 months ending August 1, 1947.⁴ As of July 1, 1949, the currently estimated population is 1.05 million higher than indicated for that date in the comparable Census Bureau forecast released in mid-February, 1949.⁵

Why is the population upsurge in the 1940's "amazing"?

First, the absolute increase is the largest of any decade in our history. The rate of increase is close to those of 1910-20 and 1920-30, and the rate of natural increase (i.e., excluding the influence of net in-migration) will prove to be of the same order of magnitude as in the two decades centered on 1900.

Second, 1940-50 was a war decade par excellence. In three earlier war decades—1810-20, 1860-70, 1910-20—the rate of population increase declined sharply. Warren Thompson, one of our most respected students of population problems, argued in two books published during the late war "that even under the most favorable conditions . . . war does have a very depressing effect on population growth. . . ." Philip Hauser, now acting director of the Census Bureau, argued this even more strongly and specifically in 1942.⁷

Third, the population developments of 1940-50 were totally unexpected. If, ten or twelve years ago, anyone had dared to predict for 1950 the figures that now seem sure to be reached, with or without the assumption of our involvement in a second world war, he would have been almost universally regarded as irresponsible if not insane. The events have falsified numerous and successive forecasts by those who were widely regarded as dependable

⁴ Registered births in 1948 were only 141,000 below the huge figure of 3,700,000 in 1947, and the birth rate in 1948 was apparently higher than in any year except 1947 since 1918. Through June 1949 there was little decline, and the estimated number of births in January-June 1949 was slightly higher than in the same period of 1948. Federal Security Agency, *Monthly Vital Statistics Bulletin*, Aug. 15, 1949.

⁵ Bur. Census, *Current Population Reports: Population Estimates*, Series P-25, No. 18 Feb 14, 1949, p. 12.

⁶ W. S. Thompson, *Population Problems* (8d ed., McGraw-Hill, New York and London, 1942), pp. 44-49; W. S. Thompson, *Plenty of People* (Cattell, Lancaster, Pa., 1944), p. 79. In the postwar edition of the latter book (rev. ed., Ronald, New York, 1948), chap. v, Thompson expressed a modified view.

⁷ P. M. Hauser, "The Impact of War on Population and Vital Phenomena," *Am. Jour. Sociol.*, November 1942, XLVIII, 309-322.

experts, after "a vast amount of population study and research." A continuation of the downtrends in rate of population increase, and in fertility rates, had been confidently expected. The events have upset, or at least called seriously in question, a whole series of convictions which social scientists generally had come to hold firmly. I must shortly say more on this third point.

Additional features of the population experience of the 1940's deserve passing mention. The married state has become more common, "single blessedness" much less so. The median age at marriage has declined. The number of families has risen much faster than the population.⁸ The infant-mortality rate has gone on declining, uninterrupted by the war. The maternal death rate, after long showing no clear trend, has declined markedly since the mid-1930's. Life expectancy has continued to increase, with no slackening of pace yet visible; and upper limits formerly suggested have been exceeded or are being approached well in advance of the dates forecast. The death rate in the upper age groups, which earlier was resistant to change, has been falling and bids fair to continue to fall. The increase in children under five in 1940-50 will probably be around 50 percent, and that of people over 65 well above 25 percent. The median age of the population, which rose sharply in the 1930's, has risen very little in the 1940's, and has actually fallen since 1945—if my guesstimates are not disproved by eventually detailed calculations. The crude death rate has continued to decline, despite the rise in the median age ever since 1810. Eventually, as the elderly and aged increase further in proportion to the total, this rate will rise; but no one can safely say how soon. The number of elderly and aged (say 60 and over) has risen rather more than forecast, but the proportion has recently risen much less and may be lower in 1950 than in 1940. The lengthening of life has been accompanied by extension of the period of vigor and potential productivity, altering the significance of the upper age groups.

The upsurge of population in the 1940's, moreover, has been accompanied by important net gains in the level of living. These gains, much greater than in the preceding decade, are beyond question, even though none of the common measures or indicators are trustworthy as to the extent of the improvement, and we have

⁸ Bur Census, *Current Population Reports: Population Characteristics*, Series P-20, No. 25, Aug. 19, 1949

yet no reliable over-all index. Indicative but not definitive are the decline in infant-mortality rates, the increase in per capita consumption expenditures deflated by the Consumer Price Index (35 percent between 1929 and 1948), the expansion of services provided at public expense, and a variety of others. If we could use medians instead of arithmetic averages, and make suitable adjustments for the altered age distribution of the population, the gains would show up as even more striking. The phenomenon is the more impressive because 1940-50 was a war decade.

Some Forecasts in Retrospect

Let us see how a few forecasts have stood the test to date. Bear in mind the figures I have already suggested: a true population July 1, 1950 of around 152 million; a 1940-50 increase of at least 19 million; and a 1940-50 rate of increase of about 14.4 percent.

The best forecast of the 1950 population that I have found is P. K. Whelpton's first published in 1928 (*Am. Jour. Sociol.*, Sept. 1928, XXXIV, 253-70). It will be remarkably close to the true figure, though the implied rate of increase in 1940-50 (9.7 percent) will be far below the true one. Ironically, however, Thompson and Whelpton soon abandoned this forecast. The one that they made for the President's Research Committee on Social Trends, published in 1933, and all of their subsequent ones, have been too low, both absolutely and relatively.

Pearl and Reed's 1920 forecast for 1950, with their logistic curve derived from data for 1790-1910, will also be respectably close to the true figure, though probably 3-5 million too low. It has not been disavowed, though their confidence in it was weakened when the 1940 census showed their forecast for that year to be considerably too high.⁹ Here also the implied rate of increase in 1940-50 (9.1 percent) is much too low.

The most influential series of "projections" were made in 1935-36 by Thompson and Whelpton for the highly impressive Committee on Population Problems, and published in its reports to the National Resources Committee, October 1937 and May 1938.¹⁰ The authors gave me the impression that they preferred the projection based on their assumptions of medium mortality, medium fertility,

⁹ *Science*, Nov. 22, 1940, pp. 468-488.

¹⁰ *The Problems of a Changing Population* (Washington, 1938).

and no net in-migration, which we may abbreviate as "*mm0*."¹¹ This pointed to a 1950 population of 140.6 million, a 1940-50 increase of 8,568,000, and a rate of increase of 6.49 percent. These, of course, were far too low. What I took to be their second preference, assuming low fertility instead of medium (*ml0*), indicated a 1950 population of 137.1 million, a 1940-50 increase of 5,776,000, and a rate of increase of 4.4 percent. In retrospect, this appears absurdly too low, but it won more endorsement than criticism at the time.¹² I have recently learned that Whelpton then preferred the *mm100* or *mm200* projection.

The highest projection in this 1937-38 series of six—assuming medium mortality, high fertility, and an average of 100,000 net in-migrants per year (*mh100*)—pointed to a 1950 population of 144.2 million, a 1940-50 increase of 11,751,000, and a rate of increase of 8.87 percent. A still higher projection on the assumptions of low mortality, high fertility, and 200,000 net in-migrants per year (*lh200*), published in the October, 1947 document pointed to 146.8 million in 1950—slightly nearer the truth but still much too low. *In fact, despite war losses, mortality has been below the "low" assumption, in-migrants have averaged over 100,000 per year since 1940, and fertility has been far above the "high" assumption.*

The revised projections which Thompson and Whelpton made in 1941-42 for the National Resources Planning Board, published in August 1943, were little nearer the eventual truth.¹³ They still appeared to lean toward the *mm0* projection, indicating a 1950 population of 143.9 million, a 1940-50 increase of 11,364,000, and a rate of increase of 8.57 percent.¹⁴ The slightly higher projection, which the Twentieth Century Fund chose to use in its magnum opus, *America's Needs and Resources* (1947)*—*mh0*, implying "high" fertility instead of "medium"—pointed to a 1950 population of 144.7 million, a 1940-50 increase of 12,174,000, and a rate of increase of 9.19 percent. The highest of the twelve projections given

¹¹ The precise meanings attached to these various assumptions have been changed from time to time, but for the purpose in hand the changes are of minor importance. I prefer the clumsier but more precise term "in-migration" to the commoner but looser one "immigration."

¹² This was evidently the projection on which Hansen relied in his presidential address of December 1938. Alvin H. Hansen, "Economic Progress and Declining Population Growth," *Am. Econ. Rev.*, March 1939, XXIX, 1-15.

¹³ W. S. Thompson and P. K. Whelpton, *Estimates of Future Population in the United States, 1940-2000* (Washington, 1943).

¹⁴ The Bureau of Agricultural Economics evidently relied upon this forecast in its postwar studies published in 1945.

in this 1943 document, on *mh100* assumptions, pointed to a 1950 population of 145.2 million, a 1940-50 increase of 12,674,000, and a rate of increase of 9.56 percent. All of these, moreover, were on the additional assumption of no war losses.

In 1945-46 Whelpton made another series of projections with the aid of the Census Bureau, which the Bureau published in 1947.¹⁵ Though over half of the decade had elapsed, and war losses were approximately known, the apparently preferred *mm0* projection, pointed to a 1950 population of 145.5 million (or 146.3, if adjusted for underenumeration of children in 1940), a decennial increase of 13,791,000, and a rate of increase of 10.47 percent.¹⁶ The Census Bureau adopted this projection as its own forecast, and it still stands as the official forecast for years beyond 1960. The highest of the eight projections then given, made on the assumptions of low mortality, very high fertility (averaging 3 million births a year in 1946-50), and an average of 200,000 in-migrants per year after 1945, pointed to a 1950 population of 148.0 million (148.8 if adjusted . . .), a 1940-50 increase of 16,317,000, and a rate of increase of 12.39 percent. Even this extreme projection was too low.

Finally, early in 1949, well toward the end of the decade, the Census Bureau released new forecasts, for the first time giving preference to an assumption involving appreciable net in-migration—*mm125*, implying one million in-migrants in the eight years ending July 1, 1955. This led to forecasts of the 1950 population as 149.9 or 150.7 million, according to whether the basis was unadjusted or adjusted for underenumeration of children in 1940. Both are now sure to be exceeded. The implied rate of increase in 1945-50 was 7.4 percent; actually it will approach if not exceed 9 percent.

Ten months ago the standing official forecast for 1970 was, in round figures, 160 million, and this was the figure commonly used by economists.¹⁷ Six months ago the revised official forecast indi-

¹⁵ P. K. Whelpton, *Forecasts of the Population of the United States, 1945-1975* (Bur. Census, 1947).

¹⁶ This was first published in Bur. Census, *Population—Special Reports*, Series P-46, No. 7, Sept. 14, 1946. Black and Kiefer relied on this forecast in their 1948 discussion of "The Food Needs of the United States," under the sponsorship of the National Planning Association. J. D. Black and Maxine Kiefer, *Future Food and Agriculture Policy: A Program for the Next Ten Years* (McGraw-Hill, New York and London, 1948), chap. xiii, esp. p. 119.

¹⁷ See sources cited in the preceding footnote, and P. A. Samuelson, *Economics: An Introductory Analysis* (McGraw-Hill, New York, etc., 1948), p. 30.

cated that this figure would be reached in 1960. Evidence now available strongly suggests that our true population will reach 160 million during 1955, if not earlier. Is this not startling?

While successive forecasts from 1937 to 1949 improved in approaches to the true population of 1950, all were too small by roughly one million for every year between the date of forecast and the publication of the target date. This suggests a conservative bias. Most influential and persistent has been the reiterated conviction that the fertility rate (a refined version of the birth rate) would soon fall from its supposedly abnormal peak to resume its interrupted decline. On this crucial point the evidence is still running contrary to the assumption.

In October 1945 Whelpton forecast 13.5 million births in the five years ending July 1, 1950. In March 1947, as his document was about to go to press, he raised this to 15 million.¹⁸ If he were revising again in August 1949, on the basis of births reported through June 1949, he might well put his medium estimate at 17.5 million. Here is at once an extraordinary indication of the lack of basis for a reliable forecast, and an indication of the continuation of a high rate of increase well beyond the time when it was supposed to have dropped.

Lynn Smith wrote not long ago: "To our human reservoir of 140 million people, each new year adds about two and one-half million units, draws off about one and one-half million. But the net change in any one year is far less than one percent, and anything greater would be phenomenal."¹⁹ Actually the figure of 140 million was passed in 1945, and in each of the eight years since 1941-42 the net increase of population has "phenomenally" exceeded one percent. Even the latest forecasts of the Census Bureau, already proved too conservative in 1947-48 and 1948-49, imply continuance of a rate above one percent through 1950-51, if not through 1951-52. In retrospect, Smith must have been unduly impressed by the 1930's, for our annual rate of increase has been below one percent *only* in 1918-19 and in the eleven years from 1930-31 to 1940-41.

We should not expect an indefinite continuance of the high crude birth rate, the huge number of births, and the high over-all rate of population increase that have characterized the past three years.

¹⁸ Whelpton, *Forecasts . . .* (1947), p. 33

¹⁹ T. Lynn Smith, *Population Analysis* (McGraw-Hill, New York, etc., 1948), p. 389.

Declines in these figures are likely within a decade, if merely because of the small number of American babies born in the 1930's. We need not be surprised if in some years of the 1950's the rate of population increase should fall well below one percent, even if we avoid a repetition of the major depression of the 1930's. But it is already clear that the huge number of births in the 1940's has laid the basis for another population upsurge in the 1960's and 1970's, unless fertility should fall far below the levels of the 1930's.

As to long-term forecasts, say for 1980, 2000, and beyond, I merely warn that none of them can be trusted. In the light of the productive potential the 1940's have proved that we possess, even the ultimate limits of our population are assuredly much higher than Pearl and Reed calculated and reasoned when they wrote their 1920 paper.²⁰ Moulton's recent question, whether our population might conceivably double to 300 million in the next 100 years (with an eight-fold increase in the per capita consumption level),²¹ no longer seems preposterous, though it is more than 50 percent above what Pearl and Reed computed (197.3 million) as our maximum for all time.

Some will regard the change in population prospects as the end of a bright vision of shrinkage to some "economic optimum population" at least several million below that of 1945, perhaps as low as 100 million.²² Others will view it as a welcome relief from a nightmare that has seemed all too realistic. Others will see in it a mere change in our complex of problems. It is certainly that, if nothing more.

Sobering Reflections

Let me not be understood as criticizing, blaming, or attacking the population specialists and forecasters for having been wrong in their reasoned guesses. Most of those whom I quote or cite are my friends, or at least friendly acquaintances, and I could make out a pretty good case in their behalf. If they are the scholars and gentlemen I believe them to be, they will welcome my candid

²⁰ See Lowell J. Reed, "Population Growth and Forecasts," *Annals Am. Acad. Pol. Soc. Sci.*, November 1936, CLXXXVIII, 162-166, and papers cited therein.

²¹ H. G. Moulton, *Controlling Factors in Economic Development* (Brookings Inst., Washington, 1949), chap. vii, "The Potentials of the Next Century." Moulton did not forecast 300 million population in 2049; and this figure is otherwise not properly comparable with Pearl and Reed's, since they did not assume a rapid rise in per capita consumption.

²² See an amazing passage in P. K. Whelpton, *Forecasts. . .* (1947), pp. 64-65. Cf. T. Lynn Smith's observations in his *Population Analysis*, pp. 3-4, 388-389.

exposition, and not resent it, though perhaps regretting that they had not beaten me to something better. Surely we are all devoted to the search for truth, and have to learn by our own mistakes.²³ If confessions were in order, I have many sins to confess, and I take no pride in my own forecasting record.

Though we all know that forecasting is inherently hazardous, we have tended to believe what Baker told the International Conference of Agricultural Economists in August 1930: "The population of the United States ten, twenty, even fifty years hence, can be predicted with a greater degree of assurance than any other economic or social fact, provided the immigration laws are unchanged."²⁴ Conceivably this may still be literally true; if so, it reflects most adversely upon the reliability of other forecasts. When in 1939 I publicly dissented from this view as to long-term forecasts, I clearly implied that population forecasts up to 30 years might be accepted with reasonable assurance.²⁵ In this I was gravely in error, as both the 1930's and 1940's have shown. I am ashamed that, like most of my fellow social scientists, I have so long accepted the conclusions of the population specialists with naïve faith. We ignore at our peril this general rule: we can ill afford to accept uncritically, and use as authoritative in our own work, the results of any other group of specialists. There is need of much more joint cultivation of zones in which economics overlaps other fields of specialization.

Heretofore I have been merely a "consumer" of population data and forecasts. I was "stabbed broad awake" last fall, when the Census Bureau raised its forecast for 1950 over five million above what it had predicted two and one-half years earlier. After recent careful study of a great deal of the work of the specialists, I have increased admiration for their technical achievements and assemblies of data, and profound sympathy for them as they have responded to incessant demands that they pick a projection and call it a forecast. But as of mid-1949, I have very limited respect for the judgments and opinions used in making this choice. I am also

²³ Let me quote two sentences from Stuart Chase (*The Proper Study of Mankind* . . . , Harper, New York, 1948, pp. 20, 187): "The whole point of science, says Oppenheimer, is to invite the detection of error and welcome it. . . . Real scientists take pride in their discipline and are concerned when careful forecasts go wrong."

²⁴ O. E. Baker, "Population Trends in Relation to Land Utilization," *Proc. Second Internat. Conf. of Agr. Economists* (Menasha, Wis., 1930), p. 284.

²⁵ J. S. Davis, "The Next 100 Years of the American Statistical Association," *Jour. Am. Stat. Assn.*, March 1940, XXXV, 266.

disturbed that, so far as I can ascertain, the guild of population specialists has minimized the errors of judgment, published no serious investigation into the sources of error, and been slow to warn the rest of us that several basic assumptions which have long been cherished are either unsound or seriously questionable, even if definitive proof is not at hand. There is only slight encouragement in the masterly understatement in *Population Index*, April 1949 (XV, 123): "Until recently the course of population development in Western nations was generally believed to be well charted and understood. This is now a matter of some doubt." But there are doubtless good reasons for this special case of "cultural lag."

As I see it now, it is a duty of interlopers like myself, and of consumers of population data like yourselves, to insist that old ideas be candidly reexamined in the light of evidence now available, that new ideas and evidence be sought, and that the cooperation of other specialists be enlisted in these tasks. Meanwhile, it is disheartening to have to assert that the best population forecasts deserve little credence even for five years ahead, and none at all for 20-50 years ahead. Perhaps better techniques can be found. If not, there will be a gain if we admit that our population cannot be forecast within *any* reasonable margin of error, beyond a year or two.

My samplings of economic literature through mid-1949, and of individual economists personally, indicate that the great majority of our economists, even the ablest ones, are not awake to our radically changed population position and prospects. I forbear to cite examples, including persons in our own circle. But I adjure you—teachers, researchers, and extension personnel—to scrutinize your textbooks, lecture notes, manuscripts, and talking materials to see whether you are purveying false or obsolete ideas.

You have heard the old statement: "It ain't so much what we don't know that hurts us; it's what we know that ain't so." This is better than half true. We have a big job of *unlearning* to do. Population forecasting is *not* a simple matter. Available techniques do *not* permit reliable prediction to be made for five, ten, twenty, or fifty years ahead. The best may be *far* wrong. Our net reproduction rate is *not* near unity, but has been well above it ever since 1940. It is *not* reliable as a basis for prediction.²⁶ There is *no* assurance of

²⁶ See Bur. Census, "Recent Trends in Population Replacement," *Population—Special Reports*, Series P-47, No. 2, Mar. 27, 1947, esp p 5.

any peak population, at *any* future date. The age structure of the population does *not* "inherently" point to cessation of growth and eventual population decline. Our major population problem is *not* prevention of such decline. There is *no* adequate basis for expecting the fertility rate, or the crude birth rate, to drop to or below the level of the early 1930's and to remain at that low level. While the long-term trend of our rate of population growth may still be downward, this does *not* necessarily support extrapolation of the curve from the mid-1930's. We do well to recall Raymond Pearl's observation that in this country the word "extrapolation" is usually mispronounced with the stress on the syllable "trap." Let us be on guard against that subtle disease, "trenditis," and especially its more dangerous variant, "short-term trenditis." Finally, planning for food, agriculture, industry, schools, et cetera, can *not* be safely done on the basis of supposedly expert population forecasts.

Check up on the evidence if you discount or disbelieve what I have said; but beware of relying on those who, however authoritative they appear, are loath to change their opinions until overwhelming evidence is at hand. If we continue to build on the crumbling foundations I have described, we shall have no excuse for consequent errors in our own work.

The lag of years in our understanding of important population developments is unnecessary and inexcusable for the future, if not for the past. After all the painstaking work that has been done in the past 30 years, it is surely possible to bring social scientists roughly up to date on this subject, and to keep them so. For a fair approximation to significant truths we need not wait until the 1950 census data have been collected, tabulated, laboriously analyzed, the results of analyses published, these publications studied, and the results utilized by social scientists in other books published after considerable delay. We ought to cut the period of currency of obsolete ideas to a fraction of what it is.

There are other phases of agricultural economics and rural sociology of which much the same can be said. Our basic research needs to be tied in to our current appraisals, and the usual gap between them more effectively bridged.

Hints as to Significance

You cannot expect me, here and now, to sketch all the economic and social consequences of the population upsurge in the 1940's.

The President's Research Committee on Social Trends, in its studies in 1930-33, had revealed to their eyes a population prospect "radically different from that predicted a generation or even a decade" earlier. Population experts, they said in their report, "have projected their curves into the future and the outlook is startling."²⁷ Twenty years later it will be clear that they fell into the trap of their own extrapolations! For business, private investment, consumption, and many aspects of public policy, the true position and outlook are now radically different, not only from what was pictured in 1930-41, but also from almost everything yet available in print.

One striking change is already upon us: the flood of young children entering school. Experts had led us to believe that the population of school ages had permanently passed its peak by 1940. This peak has already been substantially exceeded. The official forecasts by age groups up to 1955, and of school enrollments by grades up to 1960, point to much higher levels in the 1950's.²⁸ Though published only last February, it is already clear that these will be too low, and no one can make a reliable prediction in this important field, beyond the point at which it is affected by future births.

Four general suggestions I have to make. First, expression of national totals in per capita terms is more than ever important, even for such figures as gross national product, indexes of industrial production, and deflated consumption expenditures.²⁹ Second, several series might well be further refined (when this can be done) to adjust for changes in age distributions; for many purposes young children, and the elderly and aged, deserve less weight than persons in age groups from 15 through 59.

Third, we should be especially alert to evidence of changing *standards* of living, in the best sense of those balanced combinations of goods, leisure, other freedoms, and family life that people desire and are willing to work and save for. The notion that consumption

²⁷ *Recent Social Trends in the United States* . . (McGraw-Hill, New York and London, 1933), I, p. xx.

²⁸ Bur. Census, "Forecasts of Population and School Enrollment in the United States: 1948 to 1960," *Current Population Reports—Population Estimates*, Series P-25, No. 18, Feb. 14, 1949

²⁹ Personal consumption expenditures in 1948, as now officially estimated, were 227 percent of those in 1929. But *per capita* consumption expenditures in 1948, *deflated* by the Consumer Price Index, were 135 percent of the corresponding figure in 1929.

is the only significant component of levels and standards of living is widely prevalent. It needs to be heavily discounted. Beyond some points, I submit, people prefer less work to more goods; more freedom to more goods and shorter hours; and earlier marriage and more than one or two children to more sharply rising consumption levels per capita. This variant of a broader law, of which the so-called laws of diminishing utility and diminishing returns are other variants, merits much more attention than it has received.

Fourth, the demographic consequences of a "full-employment policy" need to be carefully explored. Expansion of so-called social-security measures, adherence to the objective of maintaining high and stable employment, and some degree of success in this direction, may constitute important new influences on attitudes that affect population development.

The special significance for agriculture I must leave to you to explore. The population developments that have already occurred profoundly affect the demand for farm products, and the altered population prospects are important for appraisals of future demand. This applies not merely to population totals but also to age distributions, and to the outlook for the short run and the long run. In this field, as in broader ones, it is useful to look back over various analyses of the consequences of a smaller and prospectively declining population, and then make reverse adjustments for a larger and rising population. Let me give one example.

On October 30, 1936, O. E. Baker addressed the Population Association of America on the "Significance of Population Trends to American Agriculture,"²⁰ to which he had adverted briefly in his 1930 address. He began: "The prospect of the early approach of a stationary and later probably declining population in the United States and in northwestern Europe profoundly alters, in my opinion, the long-time outlook for agriculture in the United States." He then expected the rate of increase in the 1940's to be "not over one-twenty-fourth." "About 1950, perhaps before," he said, "births appear likely to balance deaths; and, unless the restrictions on immigration are relaxed, the crest of the nation's population will be

²⁰ *Milbank Memorial Fund Quarterly*, April 1937, XV, 121-134. The editors began their headnote thus: "The decline of the birth rate to continuously lower levels is no longer of merely academic concern." Another sentence is worth quoting: "Whatever may be the implication of declining fertility in this country, it is generally agreed that fundamental adjustments must be made at least in our commercial structure which has been geared to the expectation of increasing population."

reached"—at some 139 million. "The weight of evidence," it seemed to him, "favors a continued decline in births for at least two decades at a rate not much less than during the past decade."³¹ He went on to discuss some consequences of a declining population: the lowered demand for milk, as the number of children declines;³² a decline in consumption of farm products, a more rapid decline in urban than in rural population; "a less commercial agriculture"; "many of the characteristics of an economic depression, including population pressure on the poorest land", and "increasing concentration of wealth," with a transfer of "poverty to rural areas." What would the converted Baker say today?

My own guesstimate is that the domestic demand for American farm products and farmers' services will be far greater than Schultz reasoned when he wrote his book for the Committee for Economic Development.³³ If so, the outlook for our agriculture is basically much less pessimistic than he then thought. The Bureau of Agricultural Economics report on *Long-Range Agricultural Policy* submitted to the House Committee on Agriculture on March 1, 1948, also needs revision. In conjunction with our higher consumption standards, I believe that our demand for milk, meat, and other animal products will become such as to put pressure upon our ability to expand the output of these products. If so, it will contribute more to the expansion of improved pastures, and to prevention of unmanageable surpluses of grains, than we have previously had a right to expect.

³¹ I am glad to say that last month, in an address at the McGill University Summer School, Baker frankly recognized the population events of the 1940's, acknowledged that he would earlier have considered them impossible, and added: "Never, it would seem, is the future so uncertain as at present."

³² He cited four urban studies indicating that children consume 50-100 percent more milk per capita than adults

³³ T. W. Schultz, *Agriculture in an Unstable Economy* (McGraw-Hill, New York and London, 1945), esp. chap. vi. As to the foreign demand, I reserve judgment.

SIGNIFICANCE OF THE "GENERAL PRICE LEVEL" AND RELATED INFLUENCES TO AMERICAN AGRICULTURE

O. V. WELLS

Bureau of Agricultural Economics

PERHAPS the best way to start is with the statement by J. W. Tapp before the Western Farm Economics Association at Davis last June:

"It is my impression that most economic historians would agree that the more violent misbehaviors of the *general price level* can be traced directly or indirectly, to disturbances which lie largely outside the realm of the so-called 'free enterprise' segment of our economy. Certainly the most disastrous of the violent upswings in the general price level in this century can be traced to repercussions from our two major world wars, and making war is not essentially a 'free enterprise job. . . .'

"It seems to me that the prime essential for a reasonably stable price level is to live in a peaceful world. . . ."

I agree not only that the greater portion of the violent fluctuation in prices, including farm prices, over the last 35 years are attributable to our war experiences but also to the clear fact that these disturbances can hardly be charged against the free enterprise system. But I assume that none of us is interested in attacking the free enterprise system. rather, our chief interest lies in first trying to see that the system does work over the longer stretches between emergencies and, second, in endeavoring even under emergency conditions to so order our economic actions as not to create unnecessary strains during the readjustment which must inevitably lie ahead.

Having said this, I next want to advance some three or four simple propositions which will exhaust the real content of this opening statement, despite the explanatory notes which follow. These are:

Proposition 1: Aside from the extreme cases such as accompany war or all out defense preparations on a grand scale, the concept of a *general price level* is not likely to prove very useful in economic analysis, especially in endeavoring to develop or appraise specific actions in the policy fields. Rather we are more likely to be interested in a series of partial, special purpose or differential price levels and the general trend in employment.

Proposition 2: The central issue in stabilization theory as to whether (a) one or a few simple, indirect fiscal devices can be used to assure a stable American economy, or (b) a series of co-ordinate devices should be developed, the most of which assist in stabilizing some essential sector of the economy instead of serving as general influences, is steadily being resolved in actual practice along the lines of the second alternative.

Proposition 3: So far as price movements are concerned, it appears that our current economic system is such that prices or rates in many fields can be raised much more readily than they can be lowered. That is, we generally define *inflation* as the concurrent upward movement of most prices and rates; *deflation* as the downward movement of production and employment and such prices and rates as are flexible.

Proposition 4: Although the farmer's first line of defense is high level non-farm production and employment, the special circumstances surrounding American agriculture are such that some of the more difficult problems relating to farm prices and the use of farm resources are not likely to be solved, by general—i.e., monetary, tariff and fiscal management—measures either to the satisfaction of farmers themselves or even in terms of the public interest.

The "special circumstances" referred to above include an apparent capacity to produce in excess of the current effective demand originating within the United States itself, an uncertain foreign market and finally a relatively immobile set of resources along with a form of economic organization which clearly indicate that reasonably prosperous conditions in farming are in considerable part dependent upon the success of farm people in maintaining or improving their collective bargaining strength.

When I started work on these notes, I assumed that this would be one session which could move smoothly forward on a noncontroversial level since economists have generally agreed that governmental control, or at least a considerable degree of regulation, had to be exercised in the fiscal-monetary field. However, some reading and a few statistical exercises have convinced me that even this hope is not likely to be realized.

I find that modern monetary theory has become an attenuated affair and that most of the current discussions now center around fiscal theory and fiscal management. That is, "Theoretical analysis has increasingly concentrated on setting forth both the determinants of the flow of spending and the effect of the resulting spending on output and employment."¹

¹ See: Introduction to Henry H. Villard's section on monetary theory in Howard S. Ellis', *A Survey of Contemporary Economics*, published for the American Economic Association by The Blakiston Company, Philadelphia, 1948; as well as the

Some 25 years¹ ago, for example, Holbrook Working started the analytical section of his discussion of factors affecting Minnesota potato prices with the simple statement: "The first factor which must be considered is the value of the dollar" and then proceeded to divide or deflate the seasonal average prices by the B.L.S. wholesale price index as the best available measure of the general price level.

Today, the terms have changed. The Postwar Agricultural Policy Report of the Land Grant Colleges declares, "High-level employment in nonagricultural industry means more to farmers than any 'farm program' the government may attempt," and Congress itself approaches the essential problem of economic stability not by a new monetary or banking route but rather through the "Employment Act of 1946."

Some attribute this shift from older quantity theory to the aggregative income approach to the late Lord Keynes who was reasonably explicit when, in referring in the *General Theory* to certain unsatisfactory economic units or terms, he said:

"The well known, but unavoidable, element of vagueness which admittedly attends the concept of the general price-level makes this term very unsatisfactory for the purposes of causal analysis, which ought to be exact."²

preface in Albert Gailord Hart, *Money, Debt and Economic Activity*, Prentice-Hall, New York, 1948.

¹ The most recent text on agricultural prices goes some distance, but by no means all the way, toward accepting this criticism:

"The general price level is a much used yet elusive term which is subject to widely differing interpretations. While it may be described simply as an average of all prices at a given time, it is difficult to comprehend, not only because of the multitude of prices entering into the average, but also because of the differing relative importance of the component price items. There is a natural tendency on the part of some persons to minimize, if not completely overlook, prices with which they have little contact and to overestimate the importance of those prices which concern them most. . . .

"Inherent in any objective concept of the general price level is the implication of a price system. If one accepts the proposition that there is a general level of prices worthy of consideration, he places emphasis on the average involved. . . . (But) even though (certain) relations between individual prices are recognized, it is hazardous to accept the general assumption that all prices are related to the extent that they move in the same direction over a given period of time. Exceptions to such a rule are easily found.

"In view of the limitations involved, the question might well be raised: Why think of a general price level at all? In the first place, there is a strong element of truth to the proposition that prices tend to move in the same direction over a given period of time, especially if the period is long. Moreover, there is a marked central tendency in a frequency distribution of price changes of individual commodities measured over a similar period."

From Warren C. Waite and Harry C. Trelogan, *Introduction to Agricultural Prices*, Burgess Publishing Company, Minneapolis, 1948, Chapter II.

Earlier still, Keynes had observed in the *Treatise* that statistical comparisons were always difficult at best and that as a general rule, for each special purpose a separate or special index number needed to be calculated.

I am myself inclined to attribute this shift in terms and methods of measurement to other sources, including the analytical hunt for *causes* as well as *effects* and the development of national or aggregative income and expenditure statistics by the statisticians in the U.S. and the U.K. In fact, one of the beloved founders of this Association, Dr. George F. Warren, had himself anticipated the Keynesian view of index numbers in developing Bulletin 999 which the U. S. Department of Agriculture released in August 1921.

Warren's calculations in Bulletin 999 were an explanation of the situation existing in the early summer of 1921, an explanation which indicated that all wholesale prices do not rise and fall proportionately and that resort to special or partial indexes were needful. To quote.

"The index of wholesale prices in June, 1921, was 151 (basis 1909-14=100)."

"The weighted average price of 31 farm products was 106 (basis 1909-14=100). These farm products, therefore, had an exchange value or purchasing power of 70 percent of the five-year average before the war." Warren further indicated that "if farm products were omitted from the wholesale price index" the average would be higher and the farm comparison still further worsened. Warren's concentration on the differential behavior of farm prices was certainly well warranted.

But Dr. Warren and many of his contemporaries were also very directly concerned with the control or stabilization of the purchasing power of the dollar or inversely, the general price level.

To a considerable extent, this concern with respect to the purchasing power of the dollar arose from the rapid increase in the farm debt structure during and immediately following World War I. I recognize the relation between debts and changing price levels but it is not a subject that I intend to further discuss, since it seems to me that the answer lies largely in the field of more prudent management of private debts and an endeavor to see that prices received by farmers generally maintain some reasonable relation to prices paid.

This concern with money or dollar purchasing power is still

current, as witness: (1) the recent statement by Dr. T. W. Schultz that, notwithstanding the peculiar properties of parity prices, "there [still] remains among the rank and file of farm people a belief that it is money, and the value thereof, that should be managed by the Government, and not the price of eggs, cattle, butter, or of any particular farm product,"³ and (2) the efforts of the American Farm Bureau and others, including some leading banking officials and the Committee for Economic Development, to secure the establishment of a National Monetary Commission to determine, in the interests of currency stabilization, "what changes are necessary or desirable in the banking or monetary system of the United States, or in the laws relating to banking or currency, by reason of domestic or international considerations or both."

The proposal for a National Monetary Commission has recently been approved by the U. S. Senate and referred to the House. Should such a Commission be established in the near future it would embark on the first comprehensive official review of the whole U.S. monetary and credit system since the study undertaken 41 years ago under the Commission created by the Act of May 30, 1908.

The approach that such a Commission might take and its final recommendations would surely be of wide interest. However, there is little reason to believe that the work of such a Commission or changes in our currency system are ever likely to yield the simple, indirect means of stabilizing the American economy which some very competent authorities once seemed to have believed were possible. This is not to say that some very useful reforms might not result; I believe they would.

But at the same time, I also believe that the really crucial issue in current economic theory—theory which influences action more

³ This is a view which Schultz does not emphasize or further develop beyond remarking that "It is a view that has much merit, for it recognizes a significant element in the pricing problem." Schultz's accompanying suggestions for a farm policy call for a wide range of positive measures dealing specifically with agriculture in line with his express statement that "what we have experienced in agriculture suggests that vigorous, enterprising farms and equally vigorous, well-designed governmental programs may be highly complementary." So far as direct action affecting average farm prices or incomes is concerned, however, Schultz joins the modern fiscal management school indicating that the first line of defense should be to stabilize the industrial economy at high production and full employment while at the same time recommending as a second line of defense compensatory farm payments in case of business depression and unemployment.

See: T. W. Schultz, *Agriculture in an Unstable Economy*, McGraw-Hill, New York, 1945, pp. 164, 219, 220, 254 and 255.

than we generally admit—turns around the question as to whether a few simple, indirect devices will carry the load or whether a whole series of additional devices must also be developed, each of which will gradually assist in giving some greater degree of stability to a particular sector of the American economy. Certainly, practice is fast trending in this second direction and this is also increasingly true of theory as such.

For example, Oscar Lange in his *Price Flexibility and Employment* indicates that it may be necessary to endeavor to directly stabilize several key items such as wage rates and the prices of certain leading farm commodities as well as using the fiscal-monetary approach. A similar inference can be made from the Journal article which won this Association's Distinguished Publications Award a year ago, Willard Cochrane's *Farm Price gyrations—An Aggregative Hypothesis*. That is, Cochrane starts from the fact that "To an important degree agriculture represents a water-tight compartment within which there is considerable fluidity, but the connective valve between the agricultural compartment and the rest of the economy works poorly and sometimes not at all." The result is that American farmers and their representatives are strongly inclined toward the "action programs" with which we are now so familiar whenever they find themselves faced with excess supplies and falling incomes, whether the cause is due to depression at home, blocked foreign demand, or excess supplies simply as the result of sheer productive ability aided by good weather. The American labor movement has also already moved a long way along this same trail with collective bargaining, a device which tends to either stabilize or gradually increase wage rates, which are our most important single series of prices. But these are only selected examples. There are any number of fields where prices or rates are semi-independent or at best are only loosely related to any central or single dominating general price influence because of immobile resources or special factors affecting the demand for or pricing of the service or product.⁴

⁴ Perhaps attention should be called to the fact that the much used wholesale price index of the B.L.S. is itself a special purpose index, despite its comprehensive commodity coverage. That is, it covers only commodities all priced at the same stage in the marketing process. It does not accurately measure changes in the purchasing power of the dollar for the average American or his family. This is much better done by a cost of living index, nor does it measure the most important single item in business costs, wage rates. That it has been so much used is due it seems to me to three facts: First, the great war-induced swings in this and other economic

It is this general line of reasoning with respect to multiple causes for economic instability and the resultant form which this gives the modern drive for economic security which leads to Propositions 1 and 2. Meanwhile the behavior of administered prices and, equally important, union wage rates of course underlie Proposition 3.

Meanwhile we are told that the current farm movement often tends to *over value* farm products. Why?

Essentially this argument defines the special characteristics of American agriculture which leads to Proposition 4.

The case runs something like this: American agriculture has an excess producing capacity which is likely to continue in use under a free price system and which will be extremely difficult to handle even assuming a strengthening of the current trend toward government regulation. Meanwhile, the demand for farm products is so inelastic, either in terms of the ordinary commodity demand schedules of the agricultural price analyst or the more recent developed income elasticities for food, that the probable supplies of farm products can only "clear" domestic and foreign markets over the next decade or more at considerably lower relative prices than the equilibrium between prices received by farmers and prices paid which has been approximated some two or three times under conditions of satisfactory employment since 1900.

Perhaps this argument is correct, especially if we assume more or less unsatisfactory employment conditions, the failure of farm programs generally, and an increasingly weak and difficult foreign market situation. But I question each of these depressing assumptions: We shall surely endeavor to so shape national policies as to work toward a brighter outcome. Various fiscal and monetary measures will be used in this effort, but I am still skeptical of attaining perpetual prosperity simply through deficit financing or, to use a newer term, financing from non-tax resources. Something more is needed.

series are of course related; second, economists and statisticians have generally been inclined to measure prices in those markets which most clearly approximate the classical definition of a "free market" and which they considered were the more sensitive indicators of economic change; and third, the wholesale price series are easiest to obtain so it is in this field that we have the longest historical series. Carl Snyder of the New York Federal Reserve Board did endeavor to develop an over-all measure of the general price level in the 1920's. So far as I am aware, it was never much used

In conclusion, it seems to me that the four factors which most immediately determine U.S. farm prices or returns are:

(1) Consumer demand within the U.S., of which the *average level of employment* is the most important single determinant,

(2) Foreign demands, of which *the availability* of dollar exchange, or the means of obtaining it, is the most immediate single determinant,

(3) Supplies of agricultural commodities and their distribution between uses or markets, actual or in reasonable prospect, and

(4) The bargaining conditions under which farm supplies are marketed.

Perhaps the first of these factors is by all odds the most important. I think it is. However, this does not mean that the supply and foreign demand factors can be ignored, nor that farm returns are not also significantly affected by the bargaining factor. Farmers can exert a direct influence in this area, and in any event it is clear that farm programs are here to stay. Such programs may well be, probably are still only in the experimental stage, but it seems to me that farmers need some specific stabilizing devices rather than simply relying upon indirect controls of so vague an average as the general price level.

Such an approach does not accept the over-valuation theory but at the same time it does not finally answer it. In general, our studies in the Bureau of Agricultural Economics have given us reason to believe that farm prices and returns may be held at far more satisfactory levels over the next five to 25 years than was the case in the 1930's.⁵ Such an answer assumes (a) that we shall gradually develop a relatively stable peace, and (b) that farmers can count on continuing activities in the farm program field.

I know that this is a prospect which alarms some, especially with the fear that the price of favorable returns to farmers will be increasing central control and regulation. I think that there is very little chance of escaping such a conclusion in case of depression and the development of an underemployed, "static" economy. However, it seems to me that the chances are we will be able to avoid this, chiefly because we are still a young, growing nation, which leads

⁵ See table 1 in the B.A.E. report, *A Study of Selected Trends and Factors Relating to the Long Range Prospects for American Agriculture*, Committee on Agriculture, House of Representatives, Eightieth Congress, Second Session, released March 10, 1948.

me to the final conclusion which may be stated as Proposition 5:

The chances of maintaining a free, "dynamic" economy—that is, of minimizing necessary controls or restrictions and maximizing the free enterprise area—are greatest in an expanding economy, probably under conditions where many of the partial price or wage levels are slowly rising over time. The growth factors in such a system not only tend to offset some of the more undesirable effects of regulation or centralization, but also minimize the need for such measures as well as offering the only acceptable solution to our most difficult farm problem, agricultural underemployment.⁶

⁶ Such a statement with respect to the essentials of economic progress is of course open to question, especially in areas or periods of extremely rapid technological improvement. The Brookings Institution, for example, is inclined toward the argument for increasing technical efficiency, declining commodity prices, and stable wage rates, all of which should lead to an increasing "real" standard of living. Alvin Hansen, I believe, argues for a stable wholesale price level and slowly rising wage rates. There is also considerable current comment about the "money illusion" which is created by rising prices. Nevertheless, it seems to me that the primary producers and small scale businessmen who are essential to a free enterprise economy will be best provided for under the proposition as stated, especially in view of the increasing trend toward rising wage rates and costs of Government.

SIGNIFICANCE OF THE GENERAL PRICE LEVEL AND RELATED INFLUENCES TO AMERICAN AGRICULTURE: FURTHER COMMENT

J. W. TAPP

Bank of America

ONE of the purposes of a meeting such as this is, as I understand it, to enable economists to engage in their favorite pastime, which is "to point out the errors of the economists of yesterday and, of course, to perform a similar service for their contemporaries." It is in this spirit that I am addressing my remarks, first toward some of the statements and "between the lines" implications in the President's address.

While I agree in general terms with Proposition 1 as stated, it seems to me that President Wells has perhaps gone too far in suggesting the limited usefulness of the concept of the general price level. The possible usefulness of the concept in extreme cases, such as war or all out defense preparations, is admitted. But, during the past 35 years, we have been devoting an inordinate portion of our lives to living through just such "war" and "defense preparation" periods. We are still in such a period with no near term prospect that we shall soon see its end. Thus, the "exceptional" war and defense impact on the general price level and the national budget is tending to become the "usual" situation, as witness our present national budget of 35 billions of dollars for past, present and future wars (including foreign rehabilitation and occupation expenditures).

I would also add a word on Proposition 1 about the need for caution in the use of "partial" or "special purpose" price levels. In some respects we have had altogether too much use of such special purpose price indexes as a basis for the development or support of a great variety of frequently altogether inconsistent single purpose policies in the farm economics field. This is true, for example, of the much maligned parity price concept as applied to individual farm products. The single purpose goal of parity prices for farm products generally is one thing. But the application of this same idea to individual farm products as a single purpose objective is sheer economic folly to any who are interested in facilitating the inevitable agricultural adjustment problems of the present post war period.

In Proposition 2 the conclusion is stated that in actual practice a series of coordinate devices are being developed for attempted stabilization of the American Economy as contrasted with the possible attempted use of one or a few simpler indirect devices. Here again I expect that Mr. Wells may be right, but the evidence is somewhat confusing. In the first place, it is not altogether clear which policies or devices are contributing toward stability and which ones are operating in the direction of greater disequilibrium rather than greater stability. Secondly, I think it might be well to give more consideration to the possibility that the use of an extensive series of supposedly coordinate devices may, in effect, make it more difficult, if not impossible, to make effective use of the few simple devices which might form the core of a limited economic stabilization program for the American economy. Between the lines I would comment on the great difficulty being experienced in keeping our myriad economic policy devices in a coordinate pattern.

The really vital question, it seems to me, is whether or not we are making the right choice, as between the use of indirect and direct devices. If we *are* moving in the direction of a series of coordinate devices, where will we be when we finally get where we seem to be going? How long a series of devices will we have? How successful will we be in keeping them "coordinate"?

Another aspect of this problem, of course, is the nature of the goals which are established for "economic stability," whether we think in terms of agriculture or the economy as a whole. The more ambitious the goals, the more rigorous and the more dangerous must be the specific devices which are to be used for their attainment. And if we insist upon quite specific goals for each important sector of the economy and the necessary special devices to quickly attain those goals, is it altogether likely that we shall avoid the type of Authoritarian State that none of us would welcome as an overall objective?

Without attempting to overstate the case, it would be well to point out some of the advantages of using to as large an extent as possible a "few simple devices" which will contribute to economic stability. One of those devices is "money management."¹ In a recent discussion of the future of the Federal Reserve System, W.

¹ See "The Future of the Federal Reserve System," W. Randolph Burgess.

Randolph Burgess stated—"There are great advantages in trying to influence economic fluctuations through the money supply. In the first place, it can be done. The second advantage of using monetary action as a method of influencing business is that this method is consistent with democracy. You don't have to tell the individual borrower or lender what to do, but you create the conditions under which he makes his own decision.

"Admittedly, the huge national debt and responsibility for the government security market have limited the freedom of credit policy since the war But, any skeptic as to the power of money in any economy does well to examine the dramatic illustrations of recent basic changes in money values and credit policies in Belgium, Germany, and Italy. These were extreme cases, but they revealed vividly the improvement that can follow large doses of good old fashioned monetary medicine."

Burgess also makes some cogent but less hopeful comments on the use of fiscal policies or "compensatory spending" as a counter cyclical device. "According to the theory, spending should be reduced when the economic goose hangs high, and increased in depressions. So far, about all we have succeeded in doing since this theory gained official sanction has been to increase the budget in both booms and depressions. Budgets are instruments of politics, and to make them also economic tools is asking much of human nature. . . . One may summarize by saying that while the budget should be an influence for economic stability, and we should do all we can to push it in that direction, we must not be too sanguine of our success."

Without belaboring the point, and with full recognition of the limitations of monetary and fiscal devices, I believe that every consideration should be given to the attainment of maximum results from the most intelligent use of the available simple and indirect devices that contribute to general economic stability. At worst any real accomplishments in this direction will minimize the propensity to experiment with more and more ambitious detailed "controls."

We should not lose sight of the fact that it has not been many months since a great many serious students of the economic scene were acutely concerned about the possibility of further price inflation. There are powerful economic forces at work which could make it possible to maintain a high general level of employment,

production and national income. Holdings of liquid assets by individuals and corporations (*including farmers*) are at a level undreamed of in any previous period on our history. The money supply is high even in relation to recent high levels of production and income. Furthermore, as contrasted with previous postwar periods, the national debt and budget situation is such that we would appear to have for the foreseeable future a depression proof money supply and relatively low interest rates. The private debt structure is not over-extended. The security and commodity markets are not threatened by over-extended speculative commitments.

Against this type of background it should be possible for those segments of the economy, faced with post war adjustment problems, to think primarily in terms of an expanding economy and alternative opportunities rather than in terms of a return to the defensive and restrictive atmosphere of the long pre-war depression years.

In spite of the above comments, I do agree in general with the statement set forth in Proposition 4 that even the most successful use of monetary and fiscal policies will not be adequate for many of the special postwar adjustment problems of agriculture. But, they can help to maintain the high level of production and non-farm employment which is the "farmer's first line of defense." Also, if we can retain reasonable flexibility in agricultural production and price policies this "first line of defense" may become a powerful offensive force for speeding up the adjustment of our agriculture to an expanding domestic market and such uncertain foreign markets as may be salvaged.

In a world which again appears to be moving in the direction of economic nationalism and bi-lateral trading, in spite of our expensive efforts to the contrary, it is of course all-important to our agriculture to maintain the broadest possible domestic outlets and expand them wherever feasible. Obviously, more can be accomplished in this direction if the general economic climate is favorable to expansion in non-farm industrial and related activities and for those branches of agriculture which are especially benefited by a high level of domestic demand.

There are good grounds for believing that the farm adjustment problems ahead may not be as serious for most lines of agriculture as those of the 1920's and 1930's, provided we face them frankly.

The "farm programs" which Wells refers to may help if they are not saddled with impossible goals and other "impedimenta." Basically, the financial position of agriculture is much stronger than that of many other segments of the economy. This is in striking contrast to agriculture in the 'twenties and 'thirties, particularly with respect to the nature and extent of farm debts and the more realistic repayment programs. A very much larger portion of agriculture is now "commercial," including the commercial family farm which purchases its horse power in the form of petroleum products instead of growing it as feed for horses and mules. True, cash expenses represent a larger relative outlay than in earlier years. These characteristics of present day agriculture should serve as a prod to the facing of adjustment problems. Adjustments, where needed, may be less postponable than in the earlier period. But if we are to meet these problems wisely and in the long run interest of agriculture and the nation, we must have some caution about trying to force farmers to fit into the all too rigid patterns which many of the current price support and related proposals would require. And I might say, quite frankly, that this is particularly true of this great Western country which looks too the future with an expansive glint in its eye. There is real concern as to whether the Congress and "The Secretary" can always move with sufficient speed, wisdom and forbearance to indulge these expectations of long term growth.

And now I conclude these rambling remarks with another quote from farmer Thad Snow of Missouri:

"The bad guesses of the dead economists of the slow-going past ought to warn living economists against over-sureness in these swift changing times."

GENERAL PRICE LEVEL AND RELATED FACTORS: FURTHER COMMENT

F. F. HILL
Cornell University

I WOULD like to comment briefly at the outset on one or two of the more obvious problems posed by the concept of a *general price level*.

It is clear, of course, that there is no such thing as a *general price level* in the sense that all prices move in the same direction at the same time and by approximately the same amount. Although a large number and wide variety of price series move in the same direction on the up and down swings associated with wars and business cycles, there are always some which do not conform to the general pattern and even those which conform as to direction show wide dispersion with respect to the extent of their movement in a given period of time. Furthermore, if one attempts to develop an index to reflect changes in the *general price level* he is immediately confronted with the necessity of making decisions on such questions as the price series to be included, the weight to be assigned each series and a host of others that give the finished product a distinctly man-made cast, frequently bearing the unmistakable imprint of its maker.

These difficulties are by no means limited to the price level concept, however. Although it provides cold comfort to the seeker of economic truth, the concepts *full employment*, *high level employment*, and *average level of employment* present much the same difficulties and might well be substituted for general price level in Mr. Wells' quotation from Lord Keynes relating to unsatisfactory economic terms. To paraphrase: "The well known, but unavoidable element of vagueness which admittedly attends the concept of *full employment* makes this term unsatisfactory for the purposes of causal analysis which ought to be exact." Certainly when one tries to reduce the concept of full employment, high-level employment, or average level of employment (the latter term used by Mr. Wells) to quantitative terms, he is confronted by a number of annoying questions such as what groups to include in the labor force, whether to weight employment in all industries equally and a dozen others that yield nothing, it seems to me, to the problems

confronting the price analyst who has the temerity to try to reduce the concept of a *general price level* to quantitative terms.

Here we are up against the practical question of whether it is worth-while to try to reduce such concepts as *general price level*, *level of employment*, and *cost of production* to quantitative terms. It seems to me it is, although I recognize the dangers of oversimplification and the fact that for many purposes it may be more productive to study the behavior of the components of the quantitative "measures" of such concepts rather than the measures themselves. One should add that in the interests of precision, the "measure" should be labeled for what it is and not be confused with the concept. For example, the index of wholesale commodity prices prepared by the Bureau of Labor Statistics should not be referred to as the *general price level*. I doubt, however, whether either agricultural economists or farmers have been led astray by such misuse of terms. Both have wandered down some economic primrose paths but they seem to me to have been of a different character.

I would like to return now to the question of whether the concept of a general price level has or can make a contribution to our understanding of the workings of the United States' economy or whether it has merely added to the confusion and is likely to continue to do so.

In Proposition 1 Mr. Wells states that aside from extreme situations such as accompany wars or all-out defense preparations, the concept of a *general price level* is not likely to prove very useful and that we are more likely to be interested in a series of special purpose or differential price levels and the general trend in employment. Reserving comment for a moment on the two stated exceptions to Mr. Wells' general proposition, which exceptions by the way seem to me to be quite important, I agree with the emphasis placed on studies of differential price behavior. Granted it is important to study the movement of individual and special purpose price series, it does not necessarily follow that a study of "general" price movements as reflected by some such index as the BLS index of wholesale commodity prices is unimportant. History is replete with instances in which the prices of an extremely large number and wide variety of goods and services have moved in the same direction at the same time. It seems to me such movements provide reasonable grounds for the assumption that under such circumstances prices may be moving in response to a common set of economic forces.

The fact that prices are moving in the same direction at the same time does not prove, of course, that the movement is the result of a common causal factor or group of factors. Much less does it indicate the nature of the causal relationships involved. It merely provides grounds for what seems to me to be a plausible hypothesis that, like any other hypothesis, must be carefully checked. If one feels there is no logical ground for the hypothesis that one or more major influences are likely to be at work during the broad up and down sweeps of prices which accompany wars and major business cycles; that there may be grounds for the hypothesis but no possibility of untangling or "measuring" such forces even if they exist; or that such theoretical and quantitative work as has been done constitutes a sufficient test and that the results are negative, then one must conclude that the general price level concept has nothing to offer.

My own view is that concurrent movement in a given direction of a large number of price series such as has repeatedly occurred in the past provides plausible grounds for the view that such movements are likely to be directly or indirectly in response to common causes. It is not necessary, it seems to me, for *all* prices to be moving in the same direction at the same time to make the hypothesis plausible nor for all prices to move by the same amount in a given period of time.

Emphasis on what seems to me to be the importance of continued study and analysis of factors outside agriculture affecting both agricultural and non-agricultural prices and more specifically the effect of monetary, fiscal and tariff policies on price movements does not mean:

- (1) That I think such studies should be carried on to the exclusion of other approaches. In a particular situation other factors, especially in the short run, may be equally or more important in determining the prices of particular commodities. In *all* situations other factors must be taken into account.
- (2) That I think monetary, fiscal and tariff policies exert the same relative influence on prices at all times.
- (3) That I think we are likely to discover or devise a simple mechanism that will enable us to keep the *general price level* "stable" as one might keep a hydraulic lift at a given level under changing loads by varying the pressure in the system. Price stability is a relative term.
- (4) That stabilization of the general price level in the sense of maintaining the BLS index of wholesale commodity prices at a given level

would solve all the problems of agriculture. We might still have too many resources in agriculture at a given time to yield returns at the margin deemed to be satisfactory from a social or political point of view.

You may feel that the foregoing statements in themselves pretty much wash up the general price level concept and the effect of monetary, fiscal and tariff measures upon prices; that like the Cheshire cat in "Alice in Wonderland," there is nothing left but the grin. I believe, however, that monetary, fiscal and tariff policies have had and will continue to have an important bearing on the price outlook in the United States' economy and that this is important to agriculture. It seems to me we have cycles in our economic thinking and that Mr. Wells has reached a new low in de-emphasis of the effect of monetary-fiscal-tariff measures on prices. I do not deny that we have perhaps over-emphasized the importance of these factors in the past. Mr. Wells has gone further than I would go in the other direction. I am not arguing for emphasizing these outside factors to the exclusive of other considerations. I am arguing for continuing to give attention to them.

But perhaps I am over-emphasizing Mr. Well's de-emphasis. His first proposition reads as follows:

"Aside from the extreme cases such as accompany war or all out defense preparations on a grand scale, the concept of a *general price level* (italics his) is not likely to prove very useful in economic analysis, especially in endeavoring to develop or appraise specific actions in the policy fields. Rather we are more likely to be interested in a series of partial, special purpose or differential price levels and the general trend in employment "

During a great deal if not most of my adult lifetime, which goes back further than I would like to admit, we have been either on an economic binge, or trying to get over one, brought on by war. If one agrees that monetary and fiscal factors have an important effect on prices during and following wars, it seems to me that from a practical point of view he is agreeing that they have been important during the greater part of the last 35 years.

I agree with Mr. Wells' second proposition that the issue in stabilization theory as to whether we shall use one or a few simple devices to try to stabilize the United States' economy or a series of co-ordinate devices intended to stabilize individual sectors is steadily being resolved in actual practice along the lines of the second alternative. I would add that I think this creates a problem

of major proportions, namely, the problem of co-ordinating the co-ordinate devices to which Mr. Wells refers. One may feel that our present approach to economic stabilization is the best approach or that it is the only one available from a practical point of view. Regardless of one's views on this question, I think there is no doubt but that the approach we are taking serves to focus attention on the economic problems of individual groups and to foster pressures to get a larger share of the national cake with no one except a few impotent economists worrying about the effect of this procedure on the size of the cake to be divided among various claimants.

I am also in agreement with Proposition 1 which seems to me to be causally related to Proposition 2. I think few would disagree with this proposition which states that our current economic system is such that prices or returns in many fields can be raised much more readily than they can be lowered. I would add that governmental action intended to stabilize essential sectors of the economy (see Mr. Wells' Proposition 2) is tending to steadily increase the list of inflexible prices and rates and that agricultural price support programs bid fare to constitute another major step in this direction. Instead of reducing rigidities in our economy, we are increasing them. Regardless of what one may think of the social desirability or political inevitability of developments in the fields of prices and wages during the past 20 years, it seems to me that the increasing inflexibility which is clearly apparent on all sides is undesirable from an economic point of view. I will go further and say that in my opinion, relatively high and inflexible prices and wages in the United States may well prove to be a major barrier to the successful revival of world trade which in turn has important implications for world peace. I agree with Mr. Wells and Mr. Tapp that a prime essential for a reasonably stable price level is to live in a peaceful world.

I agree with Mr. Wells' fourth proposition that monetary, tariff and fiscal measures, even if they could be and were manipulated in such a way as to "stabilize the general price level" would not automatically solve all of the problems of agriculture. To mention but one, technological changes are steadily reducing the number of persons required in agriculture to produce the nation's food and fiber. If returns in agricultural and non-agricultural enterprises are to be more nearly equal, there is need for a continuing transfer

of manpower out of agriculture into other occupations. For such transfers to take place, a number of conditions must be met including provision of jobs at wages sufficiently attractive to bring about the desired shift. The wage differential between agriculture and industry is ordinarily sufficient to effect the transfer of manpower. The limiting factor is usually jobs. These are affected by the price-cost outlook which in turn is affected by monetary, fiscal and tariff policies as well as other factors. To the extent that monetary, fiscal and tariff policy can be made to contribute to a greater degree of economic stability in the nonfarm sectors of our economy, orderly transfer of excess manpower out of agriculture will be facilitated. Instability in the nonfarm sectors of our economy constitutes a major handicap to agriculture, not only because of the greatly reduced demand for agricultural products on the down swings, which obviously is of major importance, but also because of the handicap which uncertainty adds to maintaining a desirable pattern of resource-use in agriculture.

In conclusion, Mr. Wells lists four factors which he thinks most immediately determine United States farm prices or returns. These are:

- (1) Consumer demand within the United States of which the *average level of employment* is the most important single determinant. (Italics his).
- (2) Foreign demands, of which *the availability* of dollar exchange, or the means of obtaining it, is the most important single determinant. (Italics his).
- (3) Supplies of agricultural commodities and their distribution between uses and markets, actual or in reasonable prospect.
- (4) The bargaining conditions under which farm supplies are marketed.

It seems to me the first so-called conclusion still leaves unanswered the all-important question of what factors affect the level of employment. Under our form of economic organization, employment is largely determined by the prospect for profits. Profit prospects, in turn, are determined by prospective price-cost relationships and prospective volume of sales. Question: Do monetary, fiscal or tariff policies affect profit prospects in any way and thus indirectly affect employment or is the level of employment determined solely by other factors? If the answer is that monetary, fiscal and tariff policies have nothing to do with prospects for profits, and therefore nothing to do with employment, the sooner we forget about them

as factors affecting the level of economic activity the better. It's hard for me to believe this is the case.

With respect to the second conclusion, I should have thought that tariff policy would have had considerable to do with the availability of dollar exchange to other countries which in turn admittedly affects foreign demand for United States' farm products. I gather the British have rather strong views on this question at the present time.

Supplies of agricultural products certainly will have an important bearing on farm prices and returns (conclusion three). Bargaining conditions under which farm products are marketed will also have a bearing on farm prices and returns (conclusion four) although it is easy to over-estimate the possibility of increasing farm prices and returns by strengthening the bargaining position of producers. There are plenty of examples of this in the agricultural history of the United States.

Mr. Wells' final conclusion, also stated as Proposition 5, is that:

"The chances of maintaining a free, 'dynamic' economy—that is, of minimizing necessary controls or restrictions and maximizing the free enterprise area—are greatest in an expanding economy, probably under conditions where many of the partial price or wage levels are slowly rising over time."

I agree with this general view and also with what I take to be Mr. Wells' position that there is no reason to believe our "dynamic" days are over. In other words, there is hope.

CURRENT TRENDS IN AGRICULTURAL POLICY

T. K. COWDEN

Michigan State College

THIS discussion of current trends in agricultural policy will be confined to agricultural price policy. There are other agricultural policies more important in many respects than a price policy. A farm price support program will not solve the problems of the farmer. Agriculture is inter-dependent with the rest of the economy. A high level of business activity and production, world peace, international trade and a more stable general price level are some of the other problems much more important to agriculture. We must remember that in 1939, in spite of a maze of government programs, farm prices were lower than they had been in nearly 30 years, except for the worst years of the great depression.

We are going to have farm price programs. Although we have recently experienced the most prosperous period in American agriculture, we still find almost united support among farmers and law-makers for some kind of an agricultural price program. The differences of opinion today are not in whether there should be a program, but at what levels supports should apply. The basic question is, "Are we going to have a support program to protect agriculture against low prices—with comparatively free markets above these levels—or are we going to have governmentally administered farm prices?" As of today, August 8, 1949, it looks like there is about a 50-50 chance either way. For one who believes that the free market price has a useful function to perform in our society, that 50-50 chance is too close for comfort.

The current trend is toward higher peace-time supports in agriculture, which likely means more government regulation in agriculture. The trend toward more government is not confined only to agriculture, but encompasses other segments of our economy. Regulation, in itself, is not necessarily bad; but regulation which simply defers a problem or fails to accomplish constructive ends is another question.

The politician goes further than the farmer in demanding things of government which will lead to more and more controls in agriculture. Time after time the politician has exceeded the requests of farmers from government. A classic example is the current proposal

of the Secretary of Agriculture for high support prices, which was not requested by any of the major farm organizations.

It is not the purpose of this paper to point out the shortcomings of existing farm price programs. The major weaknesses, as I see them, are that they treat symptoms rather than causes; they will require entirely too many governmental controls; and that insufficient attention is given to programs to increase the demand for farm products. Serious consideration of the demand type of approach will likely have to wait until storage stocks become even larger, or a considerable slackening in demand occurs. This does not mean that economists should cease working on the problem. It is recognized that a price program will not materially aid that large segment of the people now classified as farmers but who produce very little.

All farm price programs have trends in common; whether the Agriculture Act of 1948, the Brannan Plan, a compromise, or any other likely farm price program. If farmers accept these programs, they should be prepared to accept many of the following trends along with them. The higher the price support, the quicker they will have to accept these things. Many of these trends are not to my liking, but they are presented as I see them.

(1) The trend is toward more—not less—government control in agriculture. There may be some exceptions as compared with the peak wartime control, but not when considered in terms of controls as they existed prior to the war. Falling prices will encourage more government controls. These controls may not be confined to production controls, but may extend to other phases of farming. A review of the provisions of sugar legislation may be some indication of what is ahead for other programs. The sugar legislation provides for varying payments according to the size of the producer; a smaller producer receiving a higher rate per hundredweight than the larger producer. Persons employed on the farm have to be paid wages deemed to be fair and reasonable by the Secretary of Agriculture. Deductions from the payments are made if child labor is used. Of course, farmers have to stay within their acreage allotments. It is very doubtful if farmers can accept such programs without also accepting controls.

(2) The program will accumulate large quantities of storage stocks. Personally, I have never worried about the necessity of accumulating reserves as long as we have price fixing programs.

The unsolved problem is not how to accumulate stocks, but how to get rid of them when they are priced above, or even at the prevailing market price, without running into political difficulties. This problem needs a tremendous amount of work.

Farm programs will always be in trouble from the standpoint of the economist. The reason farmers want these programs is that they do not want to accept a free market price. Consequently, when attempts are made to have other than a free market price, we will accumulate stocks and be faced with many of the other problems that arise when market prices are interfered with.

(3) In any agricultural price program that we are likely to have, there will be production controls. Practically every postwar program written for agriculture berated production controls. Where they were given any place at all, it was stated that they are to be used as a last line of defense. Such statements were made not only by the economists, but by high government officials and farm leaders. Yet, as was always evident to some who observed the developments closely, we have seen the last line of defense become the first line of defense.

Production controls are part and parcel of a farm price program. The business man cannot understand why the farmer keeps on producing if he has more than the market demands at a satisfactory price. His reaction is, "If you have too much, do as I do, cut down your production." This type of thinking is deep-seated in the business world. Nearly 80 percent of the Congress of the United States—which has the final say on these programs—is made up of lawyers and business men. The experience of the lawyers has been in serving business clients. When farmers go to Congress for relief, the logical reaction of the Congress is, "If you have too much, reduce production." I do not mean this as an endorsement of production controls or an implication that they are the best solution possible. It is simply a statement of reality.

These production controls will become compulsory with the passing of time. When voluntary controls fail to accomplish their attempted purpose, the next step is compulsory controls. This is already evident in some of the crops grown in the South. The tendency is not to abandon controls when they fail to work, but to add more and more controls. This poses some very interesting questions, such as: What do you do with the acreages taken out of production? Will these controls lead to an overall marketing quota for the entire

farm, rather than quotas for individual products, which permits the farmer to switch to other commodities?

The statement is often made that these programs are democratic because it takes a two-thirds approval by farmers before quotas become effective. This is a slightly different concept of democracy. While democracy is based upon majority rule, it is also based upon protection of the minority. These programs also place farmers in a situation where they will be penalized heavily unless they vote "right."

(4) There will be payments from the Federal treasury direct to farmers. These are called by various names; such as, parity payments, compensatory payments, production payments, or direct payments. It is doubtful if there is any other way to operate a program for some of our perishable commodities. Economists are not being realistic when they think direct payments would eliminate production controls. They may eliminate production controls if support levels are low enough. But with the kind of support levels currently being discussed, direct payments likely will be accompanied by production controls. If this is questioned, all you need to do is try to figure out a program to maintain a high support price on some of our major perishable commodities. Remember there may be a limitation of funds that Congress would be willing to appropriate in order to make up the difference between the market price and the support price. You will find that production controls will be necessary to reduce the cost of the program. You will also find that direct payments tend to make it easier to exercise controls over the non-cooperators than if attempts are made to stabilize prices by government purchases. With direct payments, checks can be withheld from the farmer who goes over his quotas or produces a wrong weight or type of product; while if market prices are maintained, it is more difficult to put the squeeze on the fellow who doesn't go along with the program.

(5) There will be more centralization in the administration of these price programs. Farmers and farm organizations have done a lot of talking about decentralized controls, yet the trend has been in the opposite direction. It is questionable if a control program can be de-centralized! Each area and community wants to get as high an allotment as possible. These allotments have to be determined on a national basis. Farm prices are determined nationally and internationally, not in a local region.

There is also a trend to give the Secretary of Agriculture more discretionary power. This trend has taken place even though many farmers and congressmen have insisted that formulas be set up to be used in administering these price programs. The administrator himself would be very happy to have formulas so he could go ahead and act, then pass the responsibility to Congress for the consequences of the program. Yet as these programs become more complex, it is increasingly difficult to write formulas which will apply to changing conditions; consequently, more discretion is being left to the administering offices.

(6) There is a trend in Government pricing programs to pay more attention to the unimportant crops, or at least those crops which account for a smaller percentage of the total income. Emphasis is often placed on the minor crops, such as peanuts, tobacco, raisins, tung oil, walnuts and honey. It is easier to administer a program on a relatively unimportant crop than it is to tackle some of the more complicated problems. Administrators like problems they can handle.

(7) There will be a trend towards greater use of marketing agreements. At present there are in the neighborhood of thirty milk orders or agreements in fluid milk markets. This number will likely increase if prices decline. It is interesting to observe how some folks bitterly criticize government farm programs in other fields, yet endorse milk orders, which contain as much, or more, price fixing than other farm price programs. The use of marketing agreements for fruits and vegetables, which now contain less price fixing than milk agreements, will likely increase, with more pricing provisions included.

For several years legislation has been introduced in Congress which would permit the operation of marketing agreements on any agricultural product. Legislation, if introduced into Congress year after year, quite often finds its way into law.

(8) The trend will likely be towards use of more export subsidies. This raises some very serious problems in the coordination of our domestic agricultural programs with our foreign policy. We all like to deal in terms of things as they should be, or as we would like to see them—which quite often is not the way they actually are. Perhaps we might give more thought to how to work these subsidies into foreign policy so that they will be of the least possible harm.

(9) The trend has been to start these programs at a comparative-

ly low support level and then increase them with the passing of time. There are indications that this trend may be reversed by starting the programs at a high level, accumulating a lot of controls, then lowering the support price but retaining the controls.

(10) These farm programs are becoming more and more political with the passing of time. The current developments are a prime example. At one time attempts were made to administer these programs on a bi-partisan basis. This is rapidly becoming extinct, even at the local level. This type of politics is confined not only to pricing programs, but extends to some of our other agricultural programs.

(11) The trend is toward a limitation of the size of the producer that may participate fully in the program. Secretary Brannan's plan contained such a limitation. It is not the first time that limitations have been suggested or enacted into law. This type of limitation may not be enacted this year, or for several years, but it is part and parcel of the deal. If the farmers want these programs, sooner or later they can expect differential treatment between the larger and smaller producers. In all likelihood, after such limitations are established, there will be a tendency to reduce the criteria of what constitutes a large farmer. This possibility may pose some interesting questions from the standpoint of efficient farm management.

The trends in current agricultural policy which I have discussed are trends as I see them—not as I would like them to be. As educators in the field of agricultural economics, we have a grave responsibility—responsibility to point out to farmers what is involved in various approaches. We should never cease in our efforts to influence these trends into more constructive channels.

COMMENTS ON AGRICULTURAL POLICY

WALTER W. WILCOX

University of Wisconsin

I QUOTE from the last few paragraphs of Dr. Galbraith's paper, "With the pattern of agricultural policy now being followed there is plenty of room for wisdom and for error. . . . The problems connected with current policy are not ones of kind but of amount. . . . The record amply indicates we can survive the several lines of policy with which farmers have sought to counter differential market power and quite possibly with benefit to the community as a whole."¹ This last statement is particularly reassuring following the detailed historical analysis presented. Two economists never agreed more fully than Dr. Galbraith and I on these points.

I should like to make a few interpretative comments on the current scene. I want to list the six major proposals for change in the administration's controversial proposals for modifying the 1948 Act. They are:

- (1) Drop the outdated 1910-1914 base period and shift to a recent farm income purchasing power goal for determining individual price supports.
- (2) Extend the mandatory price support list to include livestock and livestock products.
- (3) Implement price supports for perishable products with production (compensatory) payments.
- (4) Restrict the price support benefits in so far as possible to keep them from encouraging further concentration of farming operations in larger than family size units.
- (5) Include minimum conservation practices as one of the requirements for eligibility for price support benefits.
- (6) Support prices at roughly 18 to 30 percent above the minimum levels specified in Title II of the 1948 Agricultural Act.

Of Secretary Brannan's six major proposals for change, in the light of my analysis and I believe in the light of recommendations of committees of this Association, the first five are distinct improvements over existing legislation.

In common with almost all agricultural economists with whom I am acquainted, I have doubts about the desirability and feasibility of Secretary Brannan's proposal to support prices at 18 to 30 percent above the minimum levels specified in Title II of the

¹ A paper read before the American Farm Economic Meetings but withheld from publication to permit additional work on it.

1948 Agricultural Act. But I do not view this proposal with alarm. One doesn't need much political experience to conclude that there is little danger that price supports at too high a level will be adopted if direct government payments are used to implement any large part of them. The real danger is that Congress will not provide effective supports at any reasonable level for those products where direct payments are the only effective means of implementation. Congress simply will not appropriate the necessary funds.

But a more serious issue emerges from another sector, one in which there has been little controversy since 1938. I refer to the great reliance placed on production controls carried over from the 1938 Agricultural Act and extended but not improved in the 1948 Act. Now Secretary Brannan proposes to extend these same controls to additional products added to the price support list. The continuation and extension of production controls on the 1938 basis might be overlooked if one could be sure that all other alternatives had been thoroughly explored and found less satisfactory. Experience indicates that used in moderation as in the 1930's our American variety of production controls may have results precisely the opposite of those expected, increasing the output of agricultural products while conserving more of our soil resources.

In judging future performance we should look at the pedigree of these American production controls. They were conceived during the frustrating experiences of the Republican Farm Board days, born under emergency conditions following the Democratic Bank Holidays, and grew to maturity in the miraculously short period of five years between 1933 and 1938 in the most unhealthy environment of continued unemployment in the history of this country. Yet no one raised any objection when both the Republican leaders in 1948 and the Democratic leaders in 1949 proposed marrying price supports designed for periods of normal economic activity to an implementing program of such unhealthy family relations.

When I tell government administrators that these controls never have worked successfully (except perhaps for tobacco) they are inclined to agree with me. But then they begin talking about conservation acres—idle acres—similar to the provisions of the 1934 AAA contracts. Leaving aside the debatable question of whether or not we are likely to get farmer and public acceptance of effective and really restrictive over-all production control programs, I want to question their economic value to farmers. Many members of

this distinguished group have noted that effective farm production controls would have anti-welfare effects. I question even their economic value to the producers they are designed to help.

Short-run monopoly gains can be obtained from production controls when producers control a large proportion of the total supply coming on the market and when the demand for the product is inelastic. This latter requirement in effect means that the possibilities of product substitution are limited. How many agricultural products fall within the above classification? Tobacco, perhaps. Cotton, wheat and rice producers must sell a substantial share of their product in the world market. They do not control a large proportion of the world supplies. They cannot obtain economic gains from restricting production except as necessary to meet the requirements of government programs.

Cotton farmers have in effect said to me, "We are not asking for a government subsidy. Just allow us to set a fair price on cotton (92 percent of parity) and adopt production controls as necessary to maintain that price." Without a government subsidy on exports or some multiple price plan in addition, I am confident their total income from cotton would be smaller as a result of their production restrictions. The same is true for wheat and rice although the problem of product substitution is much greater for cotton than for these two products. In all three cases it is unrealistic and uneconomic for the producers of these products to restrict production in the near future to the amount which would sell in the domestic market at the desired price. Domestic producers of these products do not have the machinery for raising world price levels.

The situation for corn at first appears to be different. The entire crop is domestically consumed and analyses indicate the demand curve to be inelastic. Surely farmers can obtain short-run gains by restricting production under such circumstances, but here again we run into product substitution and even more important, demand for meat animals, the end product of most corn, is only slightly inelastic. On the technical side a little improvement in feed crop production or feeding techniques, would offset any moderate production restrictions.

The point I want to make is that if farmers were given the machinery to operate production controls—and no other machinery for stabilizing and increasing their incomes—while they might stabilize their income somewhat they would almost certainly lower

it, even in the relatively short-run. The evidence is overwhelmingly against the possibility that effective production controls would obtain long-run economic gains for farmers. Why then do we use production controls as our major method of implementing price supports? Before outlining what I believe to be a more promising method of implementing price supports let me make a few background statements.

- (1) Within the foreseeable future farmers will be producing and selling in an environment of high industrial activity. Specifically, high levels of wages, employment, and economic activity by any prewar standards are far more probable than a return to the levels of unemployment and business activity of the decade before World War II.
- (2) Farm price supports are now an accepted part of the American economic scene, and in one form or another may be expected to continue to play an important part in our economy throughout the lifetime of the youngest member of this audience.
- (3) They will be extended to additional farm products as rapidly as is politically and economically feasible.
- (4) They will be maintained at as high a level as permitted by the force of economic events. (Most of the political pressure at the present time is in the direction of higher price supports, with the notable exception of the Farm Bureau and the farm economists.)
- (5) We will continue to separate domestic from world prices for export crops much of the time, at least until some new world trade considerations present their appearance.

These five propositions constitute my frame of reference when considering policies or programs for implementing price supports. Another aspect of my frame of reference is a bias toward agricultural policies which require as little direct government interference as possible with citizen actions—actions of either producers or consumers. Given these propositions and my bias toward minimum government controls I find myself exploring a program of implementing price supports similar to what I believe some people vaguely call the Babcock or livestock program.

Farmers and farm leaders who lived through the depression of the 1930's fear that we cannot maintain over-all favorable farm prices and incomes and utilize our agricultural plant to its full capacity. This of course is the crucial question. Although the big feed crops of 1948 and 1949 have raised some doubts in my own mind I still believe that we can market all we can produce at prices which will permit us to maintain a standard of living for families

on efficient farming units comparable to the standard of living of non-farm families if: (1) our present domestic buying power is maintained and continues to grow as it should in an expanding economy; (2) if we maintain postwar foreign markets at reasonable levels, and (3) if we will devise and maintain appropriate economic incentives (prices and supplementary devices) and shift our surplus resources in our major export crop areas (mainly wheat and cotton) into the production of meat animals and dairy products.

I am not yet ready to subscribe to the theory of total over-production for agriculture.

Let me restate my basic position in simpler terms. I do not believe that the loss of foreign markets and the rapid rate of technological progress is going to give us total over-production in agriculture in an economic sense. I admit the situation looks threatening—and I may be wrong. But we should remember several things—first, we have no assurance that these bumper crops in the Western Cornbelt and the Plains states will continue—second, the domestic market for our farm products in terms of purchasing power in the hands of non-farm people has tripled since the prewar years while farm production had increased around 40 percent—and finally, the shrinkage to a more normal size of the abnormally large foreign markets of recent years, if all the resources released were diverted to livestock production, would only increase livestock output by 5 to 6 percent.²

In the political debate following the announcement of the new proposals many people seem to have overlooked a key element in them. This was the proposal to support livestock prices at favorable levels relative to other farm prices. This is a really new approach in the price support field, one which holds promise of encouraging more rapid progress toward our national nutritional goals, our soil conservation goals and continued full employment at satisfactory prices for our American agricultural resources. But in the heat of the controversy over the non-economic issues, it looks very much as though the baby has been thrown out with the bath water. The compromise bill which Senator Anderson introduced, and which already has gone through many revisions now proposes to:

² An annual surplus of wheat of 375 million bushels if converted into livestock products would increase livestock production 4 percent—See "What Will We Do with Our Wheat Surplus?" by W. W. Wilcox, July 1949, Farm Policy Forum Resources shifted out of cotton and other export crops would be less than half as important as the wheat.

- (1) Raise the minimum support level range for basic commodities to 75 to 90 percent of parity with 90% supports required the first year; acreage allotments are in effect regardless of the supply of the product.
- (2) Include hired labor costs in the prices paid index, thereby raising all parity prices 5 to 6 percent at the present time.
- (3) Include dairy products, potatoes, and perhaps one or two other commodities in the mandatory support list. Specific authorization for the use of production payments on livestock was included in the first draft of the bill but has been omitted in later drafts.

Political forecasters predict that this compromise measure will pass the Senate and form the basis of a compromise with the House of Representatives. When one applies economic criteria he finds that this compromise provides as high or higher price supports on the basic crops (the crops in which market surpluses already exist) as do Secretary Brannan's proposals. This new compromise measure not only fails to include livestock products in the mandatory support list which may not be important, but as a result of the legislative history of this bill, specifically dropping the production payments feature, it is more restrictive on livestock price supports than the 1948 Act. (The 1948 Agricultural Act authorized the use of direct payments as one of the means of implementing supports and permitted price support operations on the non-basic commodities at the same levels as required and permitted on the basic commodities—up to 90 percent of parity.) Thus it seems probable that we will enter 1950 with legislation more likely to intensify and prolong existing maladjustments within our agricultural economy than either the existing legislation or Secretary Brannan's proposals.

If it were politically feasible, from a resource use and national welfare standpoint, the commodity groupings should be reversed. Livestock products should be supported at moderately high levels with a lower support level on the basic crops, but this might not give sufficient income protection to the producers of crops in excess supply. Unquestionably any system of price supports must take into account the price and income situation for individual producer groups. We are apparently committed to maintaining fairly satisfactory incomes for cotton producers, e.g., while using other means of encouraging them to shift into other lines of production. In terms of politically acceptable alternatives, relatively high price supports and acreage allotments for key surplus non-feed crops

may be the best program available. If acreage allotments for each of these surplus crops were set in terms of integrated diversion goals, rather than as at present by independent market supply formulas we would have the beginning of a farm program adapted for the economic times ahead of us rather than our present depression-dated model.

We have lost valuable ground in our current controversy. I would like to see administration and farm organization leaders get together and work out a program of price supports and implementing programs on as wide a basis and at an over-all level as high as *but no higher* than is consistent with full farm production, assuming that we will have the domestic and world purchasing power to take that volume of production at satisfactory prices except for brief cyclical periods.

But as a precautionary measure I would like to have them set up plans for dealing with the situation in case the weather and rapid technological progress do give us more total volume of agricultural products than can be sold at prices which will give farmers satisfactory incomes in relation to the cost of things they buy. Production controls should be considered on their merits, but even under these conditions I am confident that other implementing programs hold much greater promise both for farmers and for the general public. I refer particularly to the extension of multiple and class price plans for our major export and feed grain crops and class prices for some of our key foods. I hope measures of this type can be worked out in such a way as to avoid the need for direct government appropriations to finance them. Farmers will have little confidence in a program that requires large government appropriations each year. And with good reason. Because of this political consideration I place near the bottom of my list of implementing programs the Production Payment Plan we have heard so much about the last few months. But I place even lower the production controls as spelled out in the 1938 Act and as continued in existing legislation.

Parenthetically let me mention that I see no economic basis for the widespread belief that artificially maintained total farm income at above free market levels leads to inefficient national resource use. I am aware that orthodox equilibrium analysis reaches this conclusion, but equilibrium analysis does not take into consideration the dynamics of technological progress and labor mobility.

This point is discussed further in a note in the August issue of the JOURNAL. At this time I merely want to emphasize that the important consideration is relative prices and other economic incentives within agriculture. If these are kept in the right relation to each other and excess resources are channelled into the production of products having the most elastic demand schedules, I have no fear of adverse resource use effects resulting from modest transfers of income from non-farmers to farmers. National resource use in the United States is likely to be more efficient under such a program using either T. W. Schultz' or Bushrod Allin's definition of efficiency.

Returning again to the main theme, I would like to have administration and farm organization leaders work out a program for a third possible situation. They should have a price support and implementing program ready in the event serious unemployment develops. Their first program should be designed to care adequately for the usual business cycle and weather fluctuations, but a program adequate for such circumstances may not be adapted for dealing with a major depression. A separate program or a series of supplements may be needed.

Actually the working out of a program for this third situation should be relatively simple for we have mistakenly devoted almost all our postwar planning efforts to this problem.

But the crying need at the present time is for a system of price supports adapted for functioning in periods of a high level of economic activity. The critical consideration here is facilitating some long-time shifts in resource use, particularly away from current acreages of cotton and wheat toward larger acreages of grasses and feed crops and meat animal and dairy production.

FOREIGN TRADE POLICY—WHICH WAY?*

O. B. JESNESS

University of Minnesota

THE favorite bit of advice offered today on our international affairs is that "we must be realistic and start from where we are." This is inescapable. We cannot move from where we are not. If we like it where we are and if we like what we have, moving elsewhere may have no appeal. If we do not, we ought to be concerned not merely with moving but with finding a road which gives real promise of leading to improvement. Even those who may be satisfied with the status quo will do well to do some appraising. They may find that the present is not as attractive as they may have assumed. They may, in fact, discover that staying where they are may involve some troublesome problems or perhaps be impossible.

Where are we? World trade, like the Traveller among the Lilliputians, finds itself bound hand and foot by tariffs, quotas, exchange controls, state trading, and dollar shortages. Fear of war, political and economic instability and conflict between ideologies cloud the skies. The present situation is to a major extent the inheritance of two world wars and a serious world-wide depression all within the span of a single generation. These occurrences have disrupted production, markets and trade relations.

What have we done and what are we doing to meet this situation? The United States assumed a modest degree of leadership in the direction of freeing trade in the adoption of the reciprocal trade program in 1934 and its continuation since then. While it is impossible to appraise all the results of this program with nicety, there is reason for assuming that it has played a significant part in slowing down and, to some extent, in reversing the world trend towards economic nationalism. The lend-lease program adopted before our entry into the war was a more realistic facing of facts than the war loans of the previous war. While UNRRA fell short of the expectations of many, it did help to continue a flow of goods for a time after the lend-lease program ended. The efforts at international cooperation represented by the United Nations have relied heavily on our leadership. The Marshall plan is a very frank facing of the

* Miscellaneous Journal series 671, Minnesota Agricultural Experiment Station.

fact that we do have a concern with recovery of production elsewhere and the development and maintenance of world trade.

These programs surely point to our interest in international cooperation. Whether that concern is sufficiently strong to withstand pressures of short-run domestic interests which may run counter to it is something still to be demonstrated.

What are the bases of our international interests? The growing realization that the United States is not a self-sufficient nation surely is one of them. Our production in certain lines is expanded beyond the capacity of the domestic market so we have real need for export markets for both agricultural and industrial products. On the other side, we remain dependent on imports of other goods. A feature of our international trade is that to a considerable extent imports consist of raw materials from the South Pacific and Latin America, while exports tend to go more largely to Europe. Bilateral trading does not fit our situation. Multilateral trade is necessary if our exports are to pay for our imports.

There is a healthy skepticism among Americans over state trading. We have seen how states may ignore costs and use trade to help attain political or military ends. Many Americans believe strongly in leaving as much economic activity as possible in private hands. Foreign and domestic trade are not separate fields but different facets of the same thing. Control in one sector leads to control in the other. In view of this, it is unrealistic to expect freedom of operation for private endeavor on the domestic scene if actual carrying on of international trade is assigned to the state. This does not mean that governments have no function to play in international trading. Rules for playing the game are essential. It is one thing, however, to regulate trade through tariffs, exchange rates, monetary measures and the like; it is something else to carry on actual trading itself.

Among those who have any real understanding of the conditions confronting the world after the war, there is extensive agreement that the European Recovery Program has a vital function to perform. Both the production and buying power of war-torn countries were seriously disrupted. There was immediate need for improvement in the food situation and a longer-run need for the reestablishment of production and an improvement in productive capacity. In spite of short supplies of such vital materials as steel in the United States, our supplies of both food and raw materials repre-

sented abundance in comparison with Western Europe. The need was urgent; the available means with which to purchase in our markets were extremely limited.

The Marshall plan represented a realistic recognition of this problem. It saw that the solution called for some direct aid from the United States but that such aid would become primarily relief unless the European nations themselves assumed major responsibility for working out solutions to their difficulties. While the program necessarily has had to include some direct relief its major feature is a recognition of interdependence among nations in the modern world. The program rests on a hard core of reality of self-interest as far as the United States is concerned. We are beneficiaries as well as benefactors. Our well-being is inseparably linked with that of the rest of the world. Prospects for enduring peace are vitally affected by recovery of production and trade the world over.

Our questions with regard to the ERP are not so much over its objectives as over whether it is going to do enough. Production will not be fully restored and problems of dollar shortages will not all be solved by the time the present program runs out. Realistic exchange relationships need to be established. The nations involved will have to be ready to buy as well as to sell if the program is going to achieve success. Production efficiencies need improvement. Plants need rebuilding and modernization. Too much political instability still remains in some of the countries. Nor is it clear that everyone in those countries is ready to face up to the hard, cold facts which confront them. Governments are not too anxious to dwell on such facts because they are not certain of the effect on elections. The division of Europe into East and West and the sparring for power and influence which is under way create additional difficulties. How to fit Germany, particularly handled as two rather than as one economic unit, is not the least of the posers. The pace of recovery in Western Germany creates fear of competition which adds complications.

The International Monetary Fund, the International Bank for Reconstruction and Development and other forms of cooperation under the United Nations promise to be of material aid in trade and other economic relations under more normal conditions. They are not well suited to playing a major role in getting out of present dilemmas. The International Trade Organization, while not fully

established as yet, represents at least a step in the direction of providing machinery for working out better trade relations in the future. The ITO, however, is under fire from some who think that it goes entirely too far and from others who see too many weak spots and loopholes in its present organization and charter.

Naturally, enthusiasm for ITO is not to be expected on the part of those who look with disfavor on efforts to expand trade. How much merit there is to the objections of others who feel that its charter has been unduly and unnecessarily weakened by too many concessions is a matter of opinion. Much depends on how the participating nations will employ the ITO. If they use it in sincere efforts to improve trade relations and seek every means to increase its effectiveness, valuable results should flow from it. On the other hand, if they fall back on its escape clauses and protective devices to avoid making needed adjustments, the ITO might interfere with rather than aid trade expansion and recovery. This is another spot where heavy responsibility rests on the United States to provide effective leadership.

This recital while incomplete shows that the nations of the world face Herculean tasks in adjusting their economies to more effective international trade and cooperation in the years ahead. One very grave danger is that the problems of the moment may loom so large that the temptation to yield to expediency may become well-nigh irresistible. Unfortunately, such yielding will hinder rather than aid the longer-run adjustments. If persisted in, short-run expediency becomes long-run policy.

Because of her importance in world trade and the magnitude of her present-day economic problems, Great Britain exemplifies in marked degree problems which nations face today in living with the world. Great Britain could not have attained a position of prominence in the world without trade.

There may be more than a modicum of truth in the assertion that various British lines of production have not kept pace with competitors in other lands in efficiency of operation. Wars, however, certainly have played a very important part in bringing the problems of Great Britain to the fore. This is especially true of World War II. British production had to be shifted from civilian manufactures for domestic consumption and export to war materials. This shift reduced very decidedly the means for paying for imports. Moreover, available foreign exchange had to be used increasingly

for war materials. Liquidation of foreign investments provided added purchasing means for the time being but that process meant a loss of means of payment for imports later. Before the war, Great Britain lived on current production plus returns on accumulated savings. After the war, it has been limited largely to current production and part of that production necessarily has been directed to healing the wounds of war. The British people have had to deny themselves many things of foreign origin because they have been short of foreign exchange, especially dollars. They also have been forced to get along without some things of domestic manufacture because it has been necessary to push production for export rather than to concentrate on production for home needs. Clothing has remained short because woollens represented a commodity suitable for export. British cars have been going abroad rather than being sold to home buyers. In spite of this, the foreign exchange and domestic production have not been adequate to meet all needs. The limited supply of such important foods as meats and fats is one illustration of this condition. The "austerity" program in vogue in Great Britain rests on some fundamental dislocations rather than being something which has been hatched out in the fertile brain of Sir Stafford Cripps or something which can be laid at the door of the Labour Government. The austerity program, however, is only a way of living with a problem, not a remedy for it. The remedy lies in procuring the means for satisfying wants more fully through greater and more efficient production and its corollary, the recovery and expansion of trade.

The dilemma of Great Britain makes bilateral trading arrangements appeal to her as a way of getting out of difficulty, at least temporarily. One may grant the basis of such an appeal and still be concerned lest expediency be permitted to become the bricks out of which longer-run policy will be built. The employment of such devices may be contagious and the result may be that of fettering trade with so many of these arrangements that a return to anything resembling real multilateral trade may become a forlorn hope. If this should be the outcome, losses in terms of lowered levels of living and doubts over prospects for enduring peace might become staggering.

Americans who object to financial aid to Great Britain on the grounds that nationalization of some industries have taken place in that country need to recognize that the present Labour Govern-

ment did not create the basic conditions now calling for aid, and that from our standpoint what is done and how it is accomplished are much more important than who does the job. But it may be well to point out that on the other side socialization by itself will not automatically produce the changes required. Unless the British people and the British economy accept frankly the fact that lower levels of living will continue until a return to higher levels is earned by greater and more efficient production and trade, difficulties will increase. If the British people expect and demand returns that are not available from production, that nation like any other will soon find itself outdistanced by countries which face economic facts more realistically. The appeal of the "welfare state" lies in part on a concentration of attention on benefits rather than on costs. As a result the margin separating the "welfare state" from the "handout state" may be narrow. While some individuals may find it possible to get something for nothing, that is, at someone else's expense, a nation can hardly hope to do so for any length of time.

Great Britain attained its position of leadership in the world in a considerable measure because of its role in international trade. It is difficult to see how it can regain such a position without extensive restoration of multilateral trade. While the urgency of immediate problems fosters bilateralism, the British must share the concern of Americans over how to restore trade to a multilateral basis at the earliest possible time. To be sure, devaluing the pound and other steps necessary to a freer movement of goods internationally involve risks. This is what led *Fortune* (August, 1949) to ask, "Does Cripps perhaps really prefer bilateralism to risk? That is the key question about British policy and it is asked with growing insistence in Washington, in Britain, and in Europe." Those who view the risks as "intolerable" may do well to ponder the longer run consequences which may be expected to flow from a failure to face the present situation.

It would be unfair to imply that Great Britain is the only nation hesitant about taking the steps necessary to economic and trade recovery. The nations of Europe appear eager to pin their hopes on a future involving sales to their neighbors but less ready to adjust their own operations in accord with the basic principles of comparative advantage. Courageous and far-seeing action on the part of European nations generally is essential. The natural tendency is to

think primarily in terms of domestic and internal problems and solutions. It is difficult to take an optimistic view of European and world prospects unless effective action is taken to integrate economic activities. Perhaps it is too much to ask at this time for the establishment of a "United States of Western Europe" in its full political and economic import. However, it should not be asking too much of Europeans that they bend every effort toward restoring trade as well as production and that they face realistically and courageously such problems as those involved in achieving stable currency exchange relationships. Some Americans who are impatient with reluctance of Europeans to make needed adjustments contend that "he who pays the fiddler may call the tune" and insist that we should make compliance with the specific program we desire a condition of aid. However, if we prescribe the details of action, the program and the responsibility for its success or failure become ours rather than being cooperative.

While recognizing the importance of the attitudes and actions of other nations, Americans will do well to realize that our own actions, programs and policies may play an even more significant role in determining world trade policies of the future. As the world's leading nation, our concern over world peace and order is greater than that of any other nation. We have more to lose. Because of our position, our leadership is extremely influential. Recognition of this fact adds to our sense of responsibility. Self-interest focuses our attention on the need for export outlets in the years ahead and war helped to drive home to us our dependence on certain imports. The question of dollar shortage is prominent in international discussions of the day. The problem of dollar shortage is a consequence rather than a cause of international difficulties. It will not be overcome unless other countries can and will produce goods and services with which to obtain dollar exchange and those dollars cannot be obtained by them unless we stand ready to purchase goods and services from them. Our attitude towards imports, therefore, is a matter of prime importance.

The United States could not have developed as rapidly and effectively as it did if capital had not been available to us from other parts of the world. The shoe is now on the other foot. This country has reached the point where we have capital available for productive investment in other parts of the world. However, inducements for making such investments will be lacking unless there are good

prospects for obtaining and collecting returns on such investments through imports. This is a factor which we must bear in mind in our future trade policies. Our aim should be to do our part in helping develop a world of enduring peace, of stable governments, and of effective living together among nations, if we are to have the levels of living which resources make attainable for ourselves and for the world at large.

A common tendency is to think about our foreign and domestic programs as though they were separate and distinct activities which can be kept apart in water-tight compartments. This, of course, is not true. An important aspect of our policy with respect to foreign trade consequently needs to be a recognition of the fact that we cannot be unmindful of the effects which domestic programs may have on the rest of the world and our relations to it. Too many Americans appear to believe that what we do on the home front is strictly our business and consequently of no concern to anyone else. That view is entirely too narrow.

If we endeavor to maintain an artificially high price or wage structure here at home, it will be necessary to put up barriers to competition from other countries. The cry will go up that we must "protect" the American level of living and the American wage scale. It still is not recognized that levels of living and of real wages depend upon productivity, not tariff protection and trade restriction. We have difficulty in seeing in full measure the competitive problems created for other nations by our comparative skill and efficiency of production in many lines. It is anomalous for the United States under existing circumstances to be so fearful of trade.

There is direct conflict between our farm price support and our international policies. As long as we endeavor to maintain an arbitrary domestic price structure for given farm commodities, part of the program must be that of keeping imports from coming in to break down the scheme and bankrupt the treasury. Agricultural price support leads to production curtailment and Americans will hardly stand by watching imports come in while some of our most productive resources are kept in enforced idleness or devoted to less than their best uses.

The difficulties involved in achieving effective production curtailment result in the accumulation of surpluses of farm products when arbitrarily high price levels are maintained. A common assumption

is that a convenient and easy method of disposal for such surpluses lies in selling them abroad at whatever prices they will bring. This rests on the belief that there is a world market standing ready to absorb anything and everything we may see fit to turn loose on it. Such an assumption is most unrealistic in the present-day world. It overlooks entirely the knotty problem of dollar shortages. It does not face up to the vast array of trade barriers found in the world today.

Selling products abroad at less than their domestic price is a form of dumping. The nations of the world, including the United States, have restrictions against this practice. We have been quick to employ countervailing duties when products were dumped on us to create situations which we viewed as unfair competition for our own producers. Aside from that difficulty, a question also may be raised with respect to the soundness of a policy which aims to provide others with our products at lower prices than those charged our own consumers. This seems to be a doubtful way to safeguard American levels of living.

Moreover, any program involving dumping of American surpluses abroad to maintain an artificial price structure at home is inevitably nationalistic in nature. As previously suggested, barriers will have to be raised to keep foreign products from sharing in those artificially high prices. In addition, barriers will become necessary to keep dumped products from returning to our markets. This includes not only raw materials but products made from them. For example, if we dump cotton, it must be kept from making the return trip and in addition our textile industry will demand protection against foreign competition on the grounds that cotton mills abroad get American cotton at a lower price. Any extensive dumping of food products will lead to widespread demands for higher trade barriers on the grounds that foreign competitors have an advantage in resulting lower living costs for their workers. Americans have not yet faced frankly the inherent conflict between our programs of price supports and our international policies. This observation also applies to some of our officials and legislators who are bringing forth proposals involving price support.

Perhaps it will be suggested at this point that international commodity agreements provide the solution for this dilemma. While there is room for questioning commodity agreements, one is not justified in going so far as to say that there is no opportunity

at all for their employment. For example, if nations with food or other supplies to spare get together on a program of sharing these supplies with backward nations having need but lacking means of satisfying such need, the program may be very much worth while both on humanitarian grounds and as a way to improve productivity. But the possibility of using commodity agreements for such laudable purposes should not silence us in raising questions regarding other types of such agreements. Have we given sufficient consideration to the nature and consequences of these agreements? We apparently dislike and distrust cartel arrangements but are not some of the proposed international commodity arrangements glorified cartels? Markets are to be divided, rights to supply and share are to be assigned, and price limits are to be established. Will not such arrangements tend to encourage further encroachment by the state in the actual handling of trading? Will they require government controls of supplies and production to make them effective? Will they help or hinder desirable adjustments of production and of trade arrangements? Are we not selling commodity agreements to export nations on the argument that they assure a market and to consuming nations on the grounds that they assure them a supply, without sufficient examination of the consequences of such arrangements on the international trade picture and the relations of governments thereto? Surely, these questions are of sufficient merit to have our most careful study and attention before we embark on a program involving extensive reliance on commodity agreements.

Pressures being put on ECA and proposals in Congress relating to the uses of funds made available to it indicate a disturbing trend in our thinking. One of the favorite ways employed by enemies of the European Recovery Program in attempting to discredit it has been to charge that its major purpose is that of bolstering the economy of the United States by creating markets for surpluses. To the extent we yield to these pressures, we will give substance to those criticisms. Any such development is certain to create grave doubt and suspicion in the minds of others regarding the sincerity of our purposes. It will weaken our effectiveness as a leader.

If the ERP is to accomplish its objectives, the funds must be husbanded for use in purchasing goods which are most essential for economic recovery and for reestablishment of more normal

interchange and not be misappropriated to provide outlets for products merely because they happen to be in surplus in an artificially rigged domestic market.

Research in marketing is a center of interest at present. Surely, international trade is of such importance to our future that basic problems relating thereto are deserving of a prominent place among the subjects selected for study. In the work now under way, we are giving more attention to finding immediate markets abroad than to a fundamental study of what is needed for the development of permanent markets. Do we have an adequate picture of what international trade will be like after ECA completes its operations? What kinds and amounts of products may we hope to export? What will our import picture be like? How may we meet and solve problems of dollar shortages, establish stable foreign exchange relationships and restore convertibility of currencies? What are the requirements for and problems involved in a return to a greater volume of multilateral trade? What are the international ramifications of various domestic programs and proposals? Further light on these and a host of other problems is needed as guides for both our foreign and domestic policy.

An observation which a discussion of the preceding type may be expected to evoke from some quarters is that the views here expressed arise from a nostalgic longing for a return to the days of yore. But it is not a case of going back to something but a question of what we are going forward to. If we are to be fatalists and assume that the peoples of the world can do nothing to alter the stream of events, then we might as well fold our hands and wait for the worst to happen. Few of us will subscribe to any such defeatism. We will instead recognize that we can do something about shaping the course of future events and that it behooves us to study problems and consequences carefully in order that we may act intelligently. Only to the extent we do so will the future bring a satisfactory answer to the question "Foreign Trade Policy—Which Way?"

SOME FURTHER WORLD TRADE PROBLEMS—A REVIEW OF PROFESSOR JESNESS' PAPER

LAWRENCE W. WITT
Michigan State College

PROFESSOR Jesness points out that there are two roads ahead of us in foreign trade policy, an easy but purposeless road marked expediency, and a more difficult road which appears to backtrack but, he assures us, will lead to a great plain of multi-lateral trade and stable world relationships. A dozen years ago we were faced with a similar choice, yes, and even two dozen and three dozen years ago. Is it any easier with today's vast proliferation of trade restrictions to choose the high and difficult road of reduced trade barriers? Can we be any more hopeful now that domestic and international prices can be brought together?

It is appropriate to diagnose the illnesses of free multilateral trade. Why did it break down? Professor Jesness has mentioned two wars and a depression, but let us be more specific. First, and of prime importance, is the impact of the international business cycle, with war important in affecting one phase of the cycle. Many, many restrictive measures were adopted in efforts to limit the extent to which deflation affected a particular country—an export-the-depression sort of phenomenon. Second in importance are the secular changes in the conditions of consumption and production frequently becoming most serious in a depression. Examples would be the gradual expansion of synthetic fibers substituting for cotton or a continued rapid increase in rubber production while consumption increased less rapidly. To counteract such effects, interferences with trade such as the Stevenson Plan and the International Wheat Agreement were enacted. Third is the fear of war and food shortages and consequent willingness to accept nationalistic programs of self-sufficiency. Fourth are the efforts of one group or another to improve its price and terms of trade relative to other goods and factors through using tariffs, quotas, and the whole array of other restrictions. We tend to think of the fourth and forget that the other three frequently have set the stage so the fourth could operate. Trade restrictions are not solely the result of the activity of selfish pressure groups.

Is there anything in the present international situation to give us hope that these same forces will not once again draw the curtain

on our efforts to reestablish multilateral trade? Are we even making progress towards developing ideas and institutions attacking these problems? The business cycle is an important key to the whole situation yet none of the specialized international agencies has the cyclical problem as its major obligation. We are operating on an *ad hoc* basis attempting to attain stability primarily through price on a commodity by commodity basis without really facing the main issues. At one stage, the ITO charter gave some consideration to it but in the final version, the wording was watered down to innocuous form, in spite of the protests of Great Britain and other European friends.

I would like to suggest that it is high time we do some exploratory analysis based on the assumption that domestic price support programs will be with us for a long time to come. Therefore, it behooves us to try to chart a better road, and to put some purpose in the general direction of expediency, at least to learn more about the several alternatives along that road. It is possible that such mapping will discover a circuitous but perhaps politically easier route which eventually approaches the plateau of multilateralism.

A major contribution the United States can make to a long time sound world order is to maintain a stable and relatively high level of employment and purchasing power. The analysis of this problem requires a kit of tools and a body of doctrine which has not been well-integrated with the traditional neoclassical theory and hence has little to say about efficient international resource allocation. Many, of course, claim greater realism for this Keynesian analysis. It is easier to develop programs to deal with the business cycle on a national level, and such programs will not necessarily mesh with policies striving to make the international price system function; in fact policy may be developed more easily if the various national price systems are partially insulated from each other. There is much to be gained by focussing on policies which have the maximum international counter-cyclical effects rather than on international allocation of resources. International investment, for example, in many ways has been an upsetting rather than an equilibrating influence. It is questionable whether free international trade, the free flow of investment and full employment are mutually compatible within the framework of our present economic institutions. There is a tremendous waste of resources in a depression, and the world could well afford a little

mal-allocation of resources if a depression were thereby prevented. It would, of course, be better to avoid both.

Let me digress for a moment. In analyzing American agricultural policy at the domestic level, many of us have found it exceedingly useful to separate the two problems of resource allocation and income distribution. Income goals have been used to sell programs to Congress and to the people, programs which gain their objectives through modifying resource allocation. By separating these two problems far more rigorous analysis is possible, which frequently leads to pertinent suggestions for the improvement of programs. The study of resource allocation in agriculture is the heart of our field of work. To make policy conclusions in this area the main assumption is that people prefer an efficient combination of resources to an inefficient combination, a relatively easy assumption. While resource allocation affects income distribution, we have found it desirable to study income distribution separately and later to put the two together. The assumptions necessary for policy conclusions with reference to income distribution are more controversial. Usually we do not come to an agreement, but rather limit our disagreement by attacking only the extreme variations in income which are socially unacceptable.

You are all familiar with the conclusions arrived at by these methods of analysis. Agricultural and other public programs should function in such a way that the price system can operate effectively in its proper role—that of allocating resources in relation to the values of the marginal products. A considerable variation in the personal income distribution may result, but in general, the net social product is maximized. If this resulting income distribution does not fit the pattern that society deems desirable, other measures are suggested to redistribute the social product. Progressive income taxes, public education, and relief measures are well-known examples of such measures, with direct payments a more recent addition.

In the international field we have not really applied this two way analysis rigorously. Attention has been concentrated on the allocation of resources, and on somehow reestablishing the international price system. But in the last two decades, we have seen how all nations have been unwilling to permit the price system to function, primarily because the resultant distribution of income between nations and within nations was unacceptable to them.

Various steps were taken in attempts to improve their income situation, even though many recognized that the net world social product was thereby diminished. Yet, in our analytical work, we have unconsciously said, "Whatever international distribution of income results from efficient international resource allocation is a desirable and proper distribution." If the rubber producers of Malaya find the price of rubber declining from 25 to five or 10 cents per pound, they will be strongly tempted to limit marketings so as to raise prices and maintain incomes. The classical free trade answer opposes this and suggests that other lines of production should be developed. The long-run world social product would be maximized. To the rubber producer this is no answer at all since rubber is his source of income. Farmers, laborers, and others have refused to accept such *dicta* on the national scene; we can hardly blame nations and policy makers for rejecting it internationally.

Studies by Colin Clark¹ suggest that the differences in national income between industrial and primary producing countries are becoming wider. Yet we have not developed any institutions specifically designed to deal with this problem. We have adopted measures which change the international distribution of income, some consciously and others unconsciously. Professor Jesness mentioned Lend-Lease, UNRRA, and the Marshall Plan, which, through exporting food and capital goods divert income from American to foreign recipients. But we have been telling ourselves that these were loans or temporary measures until reconstruction has been largely completed. Affecting income distribution in the reverse direction are the price support programs which we and others have put into practice. Assume for the moment that such a program in the United States supports wheat at 25 cents above the equilibrium price. Within the probable elasticities of supply and demand in the short run, income is transferred from the wheat-consuming to the wheat-producing countries including ourselves. In the long run changes in resource allocation would expand wheat production in most countries, and income would be transferred from wheat importing countries to wheat exporting countries or from wheat consumers to wheat producers in the foreign consuming countries.

It is interesting to discuss the effects of an export subsidy by the

¹ In *Conditions of Economic Progress*. See also T. W. Schultz, *Food, Agriculture, and Trade*, this JOURNAL, February, 1947.

United States of exactly 25 cents per bushel. Under the circumstances above, it would neutralize completely the effects of the domestic price support program on international resource allocation and on international income distribution. An export subsidy such as this would keep the price support program entirely within the United States, except as wheat farmers in the United States might spend their additional income differently for imported goods than those who would otherwise have received the income. Thus if we assume a continued price support program probable, we find a role for the export subsidy. However, foreign nations would still consider the 25 cents to be an export subsidy against which retaliation would be justified. And obviously it would be difficult to determine the exact amount needed to offset domestic price programs, or once in operation, to keep such subsidies from becoming several times the amount needed to neutralize them internationally.

These considerations suggest that we need to face squarely on a multilateral basis the questions, "What sort of international distribution of income is socially desirable? How far and in what way can the United States contribute to this desirable income distribution?" We and other nations have an income tax designed to redistribute income among the people within our national boundaries. Logically, is there any reason why this redistribution should stop there?

We must recognize and deal with programs such as the now discarded Brazilian valorization of coffee, the West African Cacao Marketing Boards, or our own agricultural programs. If we were prepared to consider supplementary world income programs on a permanent basis, it could ease the problem of providing for a more efficient international distribution of resources. In the main, the United States has avoided using its economic strength as an international political weapon. If we were to pass a tariff on coffee, cocoa, and other tropical agricultural products to be applied as other countries discriminate against our goods, this bargaining weapon could be very effective in limiting the efforts of many Latin American countries in subsidizing competitive agricultural and industrial development. But such a weapon is dangerous and if unsuccessful, would end by increasing the price American consumers pay for these imported goods. Furthermore, as Professor Jesness points out, such bilateral trading does not serve us well with our major customers in other areas. A safer weapon though still sub-

ject to considerable dangers of political manipulation and favoritism and to legislative criticism, would be an income supplement between nations recognized as such. Such income supplements might operate through any of the familiar foreign aid programs already in operation but all integrated on an international basis and across commodities to move toward definite specific goals of social action; and made conditional upon positive measures for freeing the international price system of its many restraints and thus leading to better international resource allocation. Under the European Recovery Program it is in precisely this way that much of the progress in reducing European trade barriers has been made.

Clearing a road such as suggested is fraught with danger. Yet if, in spite of our efforts to turn into the high road proposed by Professor Jesness, we do continue in the zone of expediency we need to at least explore the criteria by which a better course can be charted. The existence of surplus supplies and the embarrassment of a government agency is certainly not an adequate basis for determining what to sell. But unless other criteria are developed, these are the ones which will be used. There are difficulties involved in determining what would be socially and internationally accepted as an improved distribution of income (it is not necessary to determine the ideal distribution). Areas where population is at or close to the Malthusian level would need to be handled separately. However, if by using direct payments of some type it would be possible to decrease the desire of most nations to warp international trade to their own advantage, positive gains would occur in total production as world resources were used more efficiently. These will repay part or perhaps all of the subsidy. The expansion in production plus the income supplements could become a powerful impetus leading toward a better world order, leading us by a circuitous route to the plateau of multilateral trade.

In bringing these ideas together, the following items seem worthy of consideration and further discussion.

(1) It is imperative that the cyclical problem be settled before any real progress can be made toward efficient international trading. Otherwise the first sign of a depression will be the signal for the intensification of quota and exchange controls either within or outside the ITO.

(2) Specific attention should be given to the problem of desirable world income goals on a multilateral basis. All existing inter-

national programs and possibly new ones would need to be revamped into an integrated program leading towards definite long time goals and not a series of separate and conflicting ends.

(3) Domestic agricultural programs in the United States should not operate to tip the terms of trade to our advantage. This, of course, assumes that the United States is at the top of the heap as far as income is concerned, and can afford to give up any measures which further increase its differential advantage.

(4) International programs should have a minimum effect in directly influencing resource allocation, but should be made conditional upon moving towards the elimination of existing wholesale interferences with international trade and the international pricing system. A difficult problem in such a program is maintaining international self-respect and continued efforts on the part of individual nations toward solving their own problems. Great Britain is a case in point.

I concur fully in the desirability of the goals and conditions of trade which Professor Jesness discussed as long time resource goals. We have made tremendous progress in the United States in our attitude towards international trade, yet in the world as a whole there is ample evidence of a less than wholehearted acceptance of the ideas of trade. The International Trade Organization has not been fully accepted. Considerable unrest is being generated as one industry after another here and abroad begins to feel the impact of the tariff cuts negotiated at Geneva. It is time to try some different techniques to lift ourselves from the morass of restrictionism into which the world has sunk. The road I suggest exploring leads dangerously close to the swamps of wholesale state interference in trading. If we lose our footing we may be worse off, but if successful, we will find that we have made real progress towards reestablishing a world trading system on a basis which has a larger measure of permanence. If we are to progress towards free trade, it is essential that we attack the problem of income changes over time and the problem of income differences between nations. Lacking this, the next economic crisis is likely to add further to the array of devices used in restricting trade.

FOREIGN TRADE PROBLEMS—FURTHER COMMENT

CHARLES M. ELKINTON
Washington State College

CAN the United States fulfill its avowed determination to establish world conditions conducive to a high level of multilateral trade? The Ægean stable of world trade is still heavily laden with exchange controls, import quotas, export subsidies, bilateral agreements, unbalanced trade, and restrictive internal economic policies. Notwithstanding our notable postwar extensions of foreign aid, the creation of the International Trade Organization and the world bank and monetary fund, the task which we have assumed remains truly Herculean.

In assaying this task and considering the signposts ahead, it appears essential to review a few postwar trends and current factors in the foreign trade picture. The United States has invested heavily in postwar world reconstruction and recovery. Government grants and credit extensions between July 1, 1945 and the end of 1948, totaled more than \$20 billion, approximately half the total being in each category.¹ Leading recipients of this aid included the United Kingdom (\$5.4 billion), France (\$2.8 billion), Germany (\$1.8 billion), Italy (\$1.4 billion), China (\$1.6 billion), and Japan (\$1.2 billion). The goods and services represented by these grants and credits contributed notably to the rapid recovery of production in many countries. However, they were insufficient, when combined with the exports of the recipient countries, to balance the cost of heavy import requirements of these areas. Consequently, foreign gold reserves and short-term dollar balances, other than those of the U.S.S.R., decreased an estimated four and one-third billion dollars during the two years 1947 and 1949 and now are down to an estimated total \$14 billion.² By the close of 1948, several countries, fearful that heavy gold and dollar drains would shortly jeopardize their limited internal financial stability, tightened import restrictions. This action was largely responsible for the reduction of United States exports of goods and services from almost \$20 billion in 1947 to \$15 billion in 1948. United States imports of goods and services, on the other hand continued to rise in 1948 and the net United States balance on goods and services

¹ This aid included \$10,471,000,000 in grants and \$9,668,000,000 in the form of loans and credits. Source: Clearing Office for Foreign Transactions, U. S. Department of Commerce.

² *Federal Reserve Bulletin*, May 1949, p. 485.

account dropped from the \$11.3 billion high point in 1947 to \$6.3 billion in 1948. United States credit advances and donations, governmental and private, accounted for all but \$100 million of the foreign trade balance deficit in 1948. This trend of events has continued on into 1949, as many of our leading customers seek non-dollar requiring sources of supply or bilateral balancing agreements. About one-third of our reduced exports are made possible by credit and donations to our customers.

Several writers at home and abroad have expressed some satisfaction with the strident effort of foreign areas to balance their dollar accounts.³ At best, this is a short-run adjustment to meet the current crisis and in no sense solves the longer-run problem of increasing the volume of world trade and creating conditions approximating international equilibrium.

Looking ahead several important and closely related questions must be raised. Is the world dollar shortage to continue as a chronic brake on world trade? Are United States imports about to level off or will they continue to expand and thus contribute to the solution of the problem of international trade stability? Will United States credit policies meet the needs of the world in the decades ahead or will we increasingly restrict our assistance to military aid and economic advice? Can internationally administered exchange rates be effectively managed so as to stimulate world trade? Can internal economic policies, at home and abroad, accomplish high level employment and production and also be consistent with an expansionist foreign trade policy?

There exists a remarkably close historical relationship between imports and industrial production in the United States.⁴ Although on the increase, our imports of goods and services are probably \$2 billion below the level which could be expected, given a continuation of the United States import-national income ratio of the past, and United States industrial production and national income at their recent level. Limited foreign production of goods and services complementary to the United States economy during the first postwar years, and United States import restrictions have largely shared the honors in holding down United States imports. Assuming that our present economic adjustment does not carry

³ Dembity, L. N., and Hirschman, A. E., "Movement Toward Balance in International Transactions of the United States," *Federal Reserve Bulletin*, May 1949, pp. 480-488.

⁴ *The United States in the World Economy, 1943*, United States Department of Commerce, p. 39.

our real income much below the present level and that it will subsequently rise, and assuming further that we will continue to relax import barriers, especially quota restrictions, the prospect for expanded imports appears reasonably good. To the extent that such a development takes place, the need for future donations to foreign areas will be reduced.

If properly timed and skillfully adjusted, changes in exchange rates may well encourage trade expansion and foster conditions of international equilibrium. The charter of the International Fund makes quite clear the intentions of the member countries to collectively employ exchange rate adjustments in support of foreign trade equilibrium without impairing the level of economic activity in the separate economies. The fact remains, however, that appropriate and mutually acceptable exchange rate adjustments remain a highly complicated task. The United Kingdom resisted devaluation of the pound in the postwar years in spite of pressure to effect the adjustment. While world markets were strong and readily accepted the total of Britain's exportable surplus, she had nothing to gain from deliberately worsening her terms of trade. With expanding output and softening world markets the British Government and officials of the monetary fund must still carefully evaluate the nature and degree of disequilibrium, the elasticity of demand for United Kingdom exports, the elasticity of imports, and the cross effects of prompt devaluation of many other currencies which followed the downward adjustment of the pound. It is more than likely that the demand for United Kingdom exports and the United Kingdom demand for imports are relatively inelastic, at least in the short run. Assuming that a moderate or substantial devaluation of the pound might give some aid to the hard pressed British economy, it would not likely solve her major problems, including high cost of power and raw materials and production inefficiencies.

The time is here when members and staff of the International Fund must demonstrate the ability of that organization to contribute to monetary conditions favorable to full and stable international trade. It must be realized, however, that the Fund is not equipped to solve all or even the major problems barring the path to international equilibrium. The first prerequisite to high level and balanced trade is a high and sustained level of economic activity in the principal trading nations of the world. An important element in achieving expanded production at home and abroad during the

next decade or two will be the foreign lending policy of the United States. The fact that United States loans and credits abroad during the last four years totaled no more than \$10.5 billion must be attributed in part to the fact that our donations were roughly equivalent to that figure. Sharply expanded United States foreign loans during the next decade or two would offer at least the following gains:

1. Remove foreign reliance on United States Government donations by 1952.

2. Alleviate the current and prospective balance of payment crises more or less chronic in a number of important trading countries, and reduce the time until the dollars, pounds, francs, lira, and other currencies of the world can be freely converted. This development would free Canada and many other countries from an extremely serious balance of payments problem which in turn jeopardizes their internal economic stability.

3. Give necessary support to the United States policy of exporting technical know-how. The fourth point in President Truman's inaugural address, the so-called Bold New Program, if thus carried out in truly bold fashion would enable many underdeveloped countries to sharply expand their efficiency and level of output. This in turn would go far toward assuring an unprecedented level of international trade.

4. Create a sustained and high demand for United States industrial and agricultural products which are geared in production for a world market.

5. Stop the strong present trend toward bilateral trade agreements. An adequate supply of dollar exchange would no doubt go far toward removing the incentive for bilateral trade and exchange clearance. Such loans may well come from both governmental and private sources to the extent of \$5 billion to \$10 billion a year. A broadening of the Charter of the International Bank for Reconstruction to enable that institution to manage such increased credit activity may be the most desirable step.

At this point I would like to pay brief respects to United States farm policy and its relation to our expansionist foreign trade policy. Support price and export subsidies are in obvious conflict with our goal of increasingly unrestricted multilateral trade. A shift of United States farm programs away from support prices to farm income support would resolve in large measure this fundamental inconsistency. If, however, the political roots of farm prices sup-

ports are deep, an early and full solution of this problem does not appear in the offing. The implications of price supports as they impinge on foreign trade policy is strikingly exemplified in a recent potato incident. The United States granted Canada a three and one-half million bushel potato quota as a part of our reciprocal trade understanding. As these potatoes came into the United States and benefited pricewise from our support price program, American potato interests lodged strong objections. The political pressure became sufficiently strong to induce the United States government to ask the Canadian Government to release us from our quota commitment. Such procedure must shake the faith of other countries in our ability to carry through on our trade commitments. Export subsidies likewise invite retaliation and bode no good for liberal trade objectives. However, to the extent that international commodity agreements cover basic commodities, to which United States subsidies are commonly applied, the major foreign objection to subsidies may be removed. In fact export subsidies become an essential feature of the program when, as in the case of wheat this year, the United States support price is above the maximum price provided for in the international agreement. Whether or not the wheat and other agreements will serve to expand trade and effect a distribution of the world's production along comparative cost lines remains to be seen. In the event of sharply declining prices and apparent excess world stocks of agreement commodities, there will come a severe test of this technique for avoiding the collapse of prices and, even more important, avoiding the uneconomic policies which were commonly applied to basic commodities in many countries during the 1930's. In light of the basic commodity market experience of recent decades and the uncertain status of international trade at this time, international commodity agreements could well be more hope than menace for future trade and economic peace.

Economic policies designed to encourage a high level of balanced foreign trade can contribute greatly to the material well being of this and other countries as well as economic and political peace in the world. Have we in the United States the collective wisdom and courage to continue and augment the world leadership which we have assumed in the realm of international economic policy in recent years? It appears not altogether unreasonable to assume that we do and in this, there is hope for the future.

IMPLICATIONS OF PARTICULAR ECONOMICS IN AGRICULTURAL ECONOMICS METHODOLOGY*

EARL O. HEADY

Iowa State College

THERE are two kinds of specialists in any field of science. One is the "tool-maker," who develops fundamental principles. The other is the "tool-user," who applies fundamental laws to specific problems. In economics the theorist is the "tool-maker" while the agricultural economist is a "tool-user." Obviously, it is also desirable that "hybrids" exist or that the "tool-user" stop to fashion tools which are needed but are not available.

Agricultural economics is simply economics applied to agriculture. It draws upon economic theory for its basic laws and analytical models. Few if any laws have emerged from empirical research in agricultural economics which were not already explained by or implied in the logic of economic theory. Economic theory, like all the theoretical sciences, is a deductive science. The deductive theorems of pure economics are the hypotheses or models to be subjected to empirical test in the various phases of applied economics.

It should be emphasized, however, that the important relationship of theory to applied economics is not one of simply developing new theorems to be proven or refuted by empirical analysis. While useful and necessary, this step can be one of idle curiosity. Theory should not be looked upon as an end or an art in itself. Conversely, the function of applied research is not solely one of searching out new models and theories in pure economics to be duplicated in or refuted by empirical observation. The important relationship is instead one of selecting an important problem in life and then drawing upon the appropriate model which provides the logic underlying the theoretical solution and suggests the pattern of empirical observation.

The important contribution of theory to empirical study can best be visualized by outlining the five fundamental steps in empirical research and the part that analytical models play in each.

I. *Formulating a problem.* A problem can be defined in either of two related but yet distinct manners. (a) *In terms of the doubt,*

* Journal Paper No. J1715 of the Iowa Agricultural Experiment Station. Ames, Iowa. Project No. 1085.

confusion, or uncertainty that faces individuals or society. Here a problematic situation is ordinarily identified through the expression of felt difficulties by individuals or groups. Problems delineated in this fashion are of the practical sort (although no more important than those outlined under b) and ordinarily call for immediate solution.¹ (b) *In terms of departure from ideal or optimum conditions.* This method of problem formulation might be termed the "normative" approach. The equilibrium conditions of economics serve directly in identifying and outlining problems. Equilibrium explains the conditions under which a given end is maximized or fully attained.² Deviation from this ideal or optimum (relative to a given end) is indicative of a "problem." The solution lies in determining the reason for deviation of the *existing state* from the *theoretical (or empirical) optimum* and explaining the means of moving from the former to the latter.³

Obviously, there is a great deal in common between the *confusion* (a) and *equilibrium* (b) methods of problem formulation. Individuals or groups express doubt or uncertainty about the *existing order* because it departs from a state which they believe is the ideal. In this vein the two methods are identical. Certainly, a great many significant problems are "uncovered" in this fashion. However, under the *confusion* method the problem is present before it is recognized. Identification of problems by means of ideals or optimums more nearly allows their anticipation and solution before the crystallization of a "problematical" situation by the public.

II. *Formulating hypotheses.* Given a problem, the most important

¹ The two concepts of a problematical situation are more nearly identical if the "confusion," "doubt," or "felt difficulty" is in the mind of the research worker rather than conveyed to him by other individuals. Emphasis is on the fact that economic theories or models delineate problems in and of themselves. The body of theory acts both as a stock of (a) calipers for indicating problems and (b) hypotheses for their solution. The important reason that these "convenient tools" relating to real life problem are available is simply because in the past they have been developed to solve real economic problems which faced (and continue to face) individuals and society. In physical sciences some of the more important discoveries grow out of abstract notions of an optimum which is not attained (in contrast to a direct expression of a problem by individuals other than the scientist.)

² The relativity of means and ends should be recognized at this point. Ends in economics are often not ultimate ends but only intermediate ends—ends to be attained only as means to more nearly ultimate ends. In this vein, the ends which we mention here need not be ultimate ends. Too, our use of the term "normative" refers to the ideal expressed by maximization of this end (whether it be intermediate or ultimate). It does not refer to "what ought to be" in an ethical sense.

³ Research is of ultimate social value only as it provides answers for this step. This is the "policy" recommendation. It is equally important for individual firms, individual consumers, and society.

step in research is formulation of hypotheses or theoretical solutions. Herein lies the design of the entire empirical procedure. Again, it is the general or basic laws of any science which function as models and hence provide hypotheses which guide the various empirical phases of investigation. The use and adaptation of theoretical models is one of the most neglected steps in empirical research. Without a theoretical solution the probability is small that one will be found in reality. In a practical vein an analytical model can be looked upon as a mental picture of the relationships (qualitative and quantitative) involved. The model also suggests conditions which must hold for maximization of a given end and thus indicates the kind and quantity of data necessary for its solution. Models are employed in all sciences and may be of either a physical or a mathematical or abstract type.

III. *Designing empirical procedures.* This step includes specification of (1) the evidence needed, (2) the statistical techniques to be employed, (3) the design of the sample or experimental method, and (4) tests of significance (or bases under which the hypotheses will be accepted or rejected). These aspects of empirical procedure should be decided upon before data are collected (in contrast to a common sequence whereby data are assembled and then questions of the appropriate statistical technique are examined). Yet these are given automatically once the analytical model is specified in step II. The appropriate statistical technique is given once the applicable model (hypothesis, theory) is formulated. In turn, the appropriate (a) sample or experimental design and (b) test of significance is given once the appropriate statistical technique is determined.⁴

IV. *Assembling and processing data.* This step is largely routine. It involves implementing the thinking which has taken place in steps I, II, and III through selecting the sample, devising a ques-

⁴ If the model involves functional relationships, as in economics, it specifies (1) use of regression analyses as the appropriate statistical techniques which in turn specifies (2) a sample stratified by the independent variable and (3) tests of significance of (or between) regression coefficients. If the model involves discrete populations and attributes it implies (1) use of means and frequency distributions as appropriate statistical techniques and hence (2) a random sample and (3) analysis of variance or chi square as tests of significance. A model indicating a closed system and a simple relationship between a dependent and independent variable would specify a single-equation, least-square regression analysis. A model indicating a system of interacting economic forces and jointly dependent variables would specify application of simultaneous equations.

tionnaire, enumerating data, etc. Too much research is initiated with step IV (data collection is substituted for thinking).

V. *Interpreting findings.* Interpretation of findings requires both statistical (mathematical) and economic analysis.

The important role of analytical models in applied research is now apparent. They provide imagination at every turn and function to systematize problems, express hypotheses, and outline empirical procedures. These elements of investigation are not distinct but flow simultaneously from single models. Greater recognition of (1) the fact that economics is the basic science underlying agricultural economics, and (2) the role of the appropriate analytical tools in empirical procedure would do much to systematize empirical research methods and findings. There is evidence that economic studies are made in agriculture without recognition of the relevant economic relationships.

Scientific Objectivity

The role of theory can hardly be restricted to use as a guide in empirical research. There are numerous economic problems where little foundation exists for empirical analysis. In some instances appropriate models have not been developed. In others, the complexity of the models is too great for currently available statistical techniques. The impossibility of quantitative observation or control of phenomena also is one of the more important conditions which excludes their application to empirical material. Then, too, there are areas in which the logic of economic postulates is obviously valid and needs no empirical verification even though it be possible.

Finally, perhaps the most important problems in life must be "solved" without empirical data. We cannot wait to "let the facts speak for themselves" simply because all the facts will never be available. Quantitative data are not available for telling farmers how to combine each infinite unit of resources. Nor are they available for fashioning a "perfect" national policy. Economic logic rather than empirical analysis must provide the guide in the *greatest number* of individual and national economic problems. Economic principle provides the vehicle whereby scientific objectivity can be attained even though the analysis must be in terms of systematic logic.

To be certain, empirical research is not always free from bias, personal evaluations and distorted inference. "Facts" are frequently

more open to bias than mental deduction. However, disagreement between "facts" can always be resolved by further observation and refined statistical treatment. Resolving conflicts is not so simple where analysis is possible largely or only in the form of scientific deduction. Yet scientific objectivity is possible even here; findings can have interpersonal validity in the sense that (1) two or more individuals analyzing a given problem can arrive at mutually consistent solutions, and (2) the *analysis* of any one individual is apart from his own personal beliefs, judgments, and values. The role of economic principle in guaranteeing scientific objectivity can best be visualized by reviewing the major conditions which give rise to conflicting solutions: (1) *The investigator does not employ systematic logic or deduction in his analysis but instead generalizes from isolated personal experience and judgment.* The difficulty here is not that the individual attempts to incorporate his own system of values into the analysis but that he fails to employ scientific thinking or the rules of logic. Personal experiences are valuable in formulating hypotheses. However, "hunches," "beliefs," or "judgments" based on a "restricted sample" seldom provide the basis for broad generalizations. The underlying assumption here is always that the "conditions" surrounding the "experience" are identical with the "postulates" of the problem in hand. (2) *Problems are defined in respect to different (levels of) ends.* Disagreement in solution may arise because investigators do not define their problem relative to a given end in the means-end scale. For example, in the economics of the individual, one research worker relating his problem to the end of *profit maximization* (an intermediate end) may rightly suggest that the farmer work more hours, use his labor "more efficiently," and hence increase income. A second investigator, relating his problem to *utility maximization* (a more nearly ultimate end), might correctly recommend that the farmer do less work and utilize labor "less efficiently" if the utility sacrificed through a decrement in money income is less than the increment in utility gained from working fewer hours. Disagreement in findings arises here not because the investigators (a) fail to employ scientific logic or (b) introduce personal value or bias, but rather because the problem is defined relative to different ends. (3) *Analysis is in terms of the individual's valuations or vested interests.* Research workers, like other individuals, are members of specific social and economic groups; they are Democrats or Republicans, farm owners

or salaried workers, investors in sheep ranching or stockholders in synthetic textiles. Further, vested interests also grow up and are perpetuated in universities and other educational or scientific organizations. These various conditions expose investigators to influences other than pure scientific objectivity. Economic policy analyzed and evaluated by individuals in terms of their own interests and norms necessarily leads to varied conclusions. Lack of agreement here grows largely out of conflict in ends at the same level in the means-end hierarchy.

Economic theory provides a common logic whereby scientific objectivity and interpersonal validity of conclusions can be guaranteed even in the absence of empirical analysis. The laws or theorems of economics are deductive set of propositions derived by the rules of logic from basic propositions called assumptions or postulates. It is these laws which fashion patterns of uniformity into a coherent system. However, since alternative hypotheses or theorems are possible, depending on the underlying postulates and the end which serves as a frame of reference, mere application of economic theory is not a sufficient condition for attainment of mutually consistent solutions. It is also necessary that (1) the problem be defined relative to a given end and (2) the underlying assumption and postulates be stated and reconciled.⁵ Accepted economic principle provides this framework for interpersonal validity of findings.

Branches of Economics

Two main branches of modern economics are "microeconomics" and "macroeconomics." Microeconomics deals with particular firms, particular households, particular industries; the price, demand, or supply of specific commodities; the productivity of or returns to specific resources and other individual relationships and quantities. It includes an important portion of marginal analysis and also considers interrelationships of particular units in describing the economic system and outlining optimum economic organizations. Macroeconomics is a study of composite economic quantities.

⁵ The "end" need not be consistent with all investigators' personal values or beliefs. It is also irrelevant whether the "end" is an "intermediate end" (means) or a more nearly "ultimate end." It is only necessary that the problem be defined relative to a *given end*. Science is concerned only with this definition of a problem (irrespective of whether the problem is important as measured by other criteria). Science is unconcerned with the end *per se* but rather, given the end, is concerned with deductions relative to the end.

It is concerned not with individual prices, commodities, industries, or households, but with such aggregates as the general level of prices, the level of employment, or the national income. Macroeconomics is especially important for certain crucial economic and policy problems given, not in individual, but in mass phenomena. It is also claimed that in aggregation the maze of individual facts and relationships can be reduced to a few variables and relationships with a greater adaptation to statistical treatment. Conversely, there is much to be claimed for the application of microeconomics. Often the particular relationships between phenomena have greater significance than the composite aggregates of which they are part.

Microeconomics has a wide range of application, especially in agricultural economics, where it is often the particular relationship, quantity, or organization which is the focus of investigation. A greater quantity of research in agricultural economics has been based upon micro than on aggregative models. However, the demarcation between particular and aggregative relationships is not as distinct as supposed when certain conventional empirical procedures are employed. *First*, while the objective often is to predict intra-unit relationships, these relationships are based on inter-unit observations. In a farm management study the analysis may be one of the relation of returns to scale. However, the empirical data is obtained not by varying the scale of one firm and observing returns within it but by observing returns for firms of different scale. Similarly, in estimating a demand curve, observations are obtained not by varying prices in a *given market* (wherein national income and other aggregative economic quantities are constant) and observation of the quantity purchased under each but by obtaining observations from *many markets* over time. The relationships derived from inter-unit data are often of an aggregative character and may not be duplicated within a unit. Given cross-sectional observations, joint relationships between variables and the aggregative character of the quantities, alternative theoretical models and empirical techniques often should be employed. One alternative is to substitute more complex models and simultaneous equations for simple models and less efficient least square regression or simpler techniques. *Second*, inferences based on particular analysis may often prove erroneous if macro relationships are disregarded. Inference from a sample may be that one farm can increase re-

turns by shifting resources from hay to grain. Yet, should all farmers shift, an opposite outcome is possible. This complex is also important in outlook work where recommendations framed in micro perspective may have an opposite aggregative outcome.

Systematic Specialization

Historically, a large number of specializations have emerged in agricultural economics. These include credit, appraisal, farm management, production economics, tenure, land economics, cooperation, prices, policy, egg marketing, milk marketing and others. These specializations grew up largely around individuals who initiated specific studies. They do not parallel systematic economic problems and analytical tools. Development of these specific strata took place before the full role of economic analysis was recognized. Specializations have been perpetuated over time through graduate training and reverence for fields *per se*. Since historical specializations make little sense in terms of systematic economic problems and analytical tools it is impossible to designate "specific theories" which fit "specific fields." Agricultural economics research will be more productive in the long run if specialization is in terms of systematic economic problems and models. For example, it is impossible to study the economics of land, capital or labor use alone and distinct from the other factors. These can be studies in proper perspective only as part of the more general production economics (resource efficiency, farm management).

Alternative specializations might be possible in terms of systematic economic analysis. The major problems of an economy are, of course, efficiency in production (including progress), equity in income distribution, and stability of the system. More specifically the basic relationships (both micro and macro) are (1) production relationships, (2) consumption relationships, and (3) market or exchange relationships for (a) resources and (b) commodities. In terms of economic analysis (systematic problems and analytical tools) the following appear to be relevant areas of specialization in agricultural economics. Reference is to particular equilibrium and basic analytical tools: (1) *Production economics as a study of resource combination and allocation*, (2) *Consumption economics as a study of household welfare and income allocation*, (3) *Market economics as a study of price, supply, demand, and other market*

relationships, (4) Resource prices as a step in analysis of functional and personal income distribution.

Perhaps additional specializations are needed. Even the fields delineated above on the basis of major economic relationships are too specialized for many problems. One area of importance is that of instability and the forces underlying economic fluctuations. The models appropriate for analysis of major phenomena (national income and employment) lie in the field of aggregative economics. However, certain micro tools are also applicable and fundamental in the study or prediction of the behavior of particular units. These might better be handled in specializations which treat the static phases of production, consumption, and market relationships in order that realism be retained.

Policy is another area which must be mentioned. However, there are no unique relationships or analytical tools (the criteria here for delineating specialization) underlying policy. It simply relates the specific quantities of several particular relationships. All economists should be concerned with "policy." There can be "policy" in terms of individual as well as of national scale. The same mathematical criteria and necessary conditions for *maximization* exist in case of any unit. The point is this, there is nothing unique about economic analysis at any level or scale. Agricultural economists should be *economic analysts* rather than extreme specialists who do not follow out a problem to its roots.

Economics of Primary Production

The most highly developed set of analytical tools in economics is that of microeconomics. Yet a great void exists in their use, even in areas where they are clearly applicable. Two centuries of economists have developed a highly refined and in some respects a time-established theory of production, economics of the firm and marginal productivity analysis. Farm management, an historic and applied counterpart, is variously defined as a study of intra-firm, inter-firm, and inter-regional resource efficiency. Perhaps no other specialization in agricultural economics is so richly tooled in principles and theory. Even then, some workers fail to recognize simple, time-established, and extremely obvious models and relationships. Note the empirical findings from many surveys and record analyses showing that "the higher the crop yield per acre the greater the

profits." These imply constant or increasing returns. Even farmers recognize this fallacy. Otherwise, the entire product for one farm or the nation would be grown on a single acre.

The theory of the firm and marginal productivity analysis define optimums for the combination of resources for a given output, the allocation of given resources between alternative products, the level of intensity for specialized resources, the relationship of returns to scale, the location of production, the timing of production in terms of seasonality and conservation, the form of resource acquisition, and other questions of resource allocation and productivity both within firms (farms), between particular farms, between particular regions, and so forth. They provide the skeleton upon which empirical analysis should be built in terms of sample design, statistical technique, and forms and sources of information.

An important portion of farm management research is in terms of static analysis. Its findings are for given prices and transformation coefficients since studies are made for one year of established price and yields (or a period of years with a given mean of these) with implication that these will continue into the future with certainty. These analyses are unrealistic. The dynamic theory of production, the analytical counterpart of farm management is often of infinitely greater value in explaining or providing the rationale of economic behavior than current static empirical analyses. Study of risk and uncertainty and the dynamics of the firm is one of the most neglected areas in farm management. Straight testing of the hypotheses which now exist in pure theory stands to be of value in itself. Studies should provide basic information not only for guidance of individuals but also as a foundation upon which policy (storage, credit, price) designed for greater stability might be based. Research should indicate the manner and degree to which resources are adapted in terms of cost structure and flexibility and adaptability; selection of enterprise, scale of operations, and capital rationing. Another neglected area of analysis is that of returns to scale in agriculture. Although the greatest proportion of farm management studies over the past three decades have examined the efficiency of farm size, there are no systematic studies which indicate the nature of economics to scale. Investigations built around existing theoretical models would be of value in removing the multitude of public myths, beliefs, and conflicts which now revolve around farm size. Studies are also needed of the interrelationship of the firm and the household in agriculture.

However, the tools of static analysis are by no means obsolete and useless. On the one hand the production economist should take the initiative and cooperate with the technical scientist in establishing the physical transformation coefficients, marginal rates of substitution and production functions such that cost and prices can be applied to suggest the most efficient combination of resources. On the other hand application should be made of the static models of marginal analysis in estimating the (value) productivity of land, labor and capital resources in particular firms, in particular farming regions, for particular products, etc. Productivity analysis of this sort should indicate the degree to which disequilibrium exists in the allocation of farm resources and hence serve as a guide to (1) individuals in adapting their resources within the business, between farming regions and between industries and (2) government policy designed to promote resource efficiency.

It is at this very point that an important distinction should be made between the findings of micro and macro analysis. Aggregative analysis of the last several years suggests that the value productivity of capital is relatively high as compared to labor under the existing structure of agriculture. Hence the interpretation that a greater total quantity of the former and a smaller quantity of the latter should be employed. Yet it is in instances such as this that aggregative analysis may break down. It does not recognize particular relationships which are all-important. A distinct and likely possibility is that should less labor be employed in agriculture, less total capital would be "required." The value productivity of a given total quantity of capital might also be less. The hypothesis is this: A smaller number of people and farms in agriculture would necessitate fewer buildings, fences, tractors and machines. The decreased investment in these specific forms of capital could, of course be invested in other specific forms, such as fertilizer, improved seed, etc. Because of the inelasticity of demand for most farm commodities, however, the value productivity of an equal total capital might well be less in the second than under the original organization of agriculture. Only particular analysis can segregate these potentialities.

Market Relationships

Specialists in price analysis have been generally aware of tools which underly their investigations. They have been concerned in estimating demand curves, supply curves, and price elasticity of

demand for specific commodities. Perhaps not enough attention has been focused on income elasticity of demand. Analysis of specific market relationships will continue to play an important role. Knowledge of composite demand curves, supply curves, and price and income elasticities for agricultural products is basic to policy. However, knowledge of these quantities for specific commodities is equally important. The composite analysis tells nothing about the outcome for individual commodities under a given price policy. If the elasticity of aggregate demand is less than unity, for example, the elasticity for a particular commodity may still be greater than one or even less than for all commodities (as an average). Obviously, particular analysis is important both as a basis in advising individuals (outlook work) and in predicting income and other consequences of price storage and similar programs.

However, particular relationships perhaps can be isolated only if the investigator is aware of the important aggregative relationships. It is now widely recognized that many of the empirical demand curves derived by least squares regression for individual commodities in the past have been only hybrid expressions of different demand and supply curves for the particular commodity and certain composite variables of the economy. Current econometric procedures suggest means whereby the aggregative forces can be treated in a system of simultaneous equations which allows isolation and more efficient estimation of a particular market's relationships and quantities.

Secondary Production or Agricultural Processing

A large portion of the analysis labeled "marketing" is not "marketing" at all in terms of basic economic relationships (supply, demand, price, elasticity). In terms of analytical models the nearest kin of the study which relates costs and volume in creamery operation, resource productivity in the packing plant or the location of soybean processing is farm management or production economics research. All are studies in the economics of the firm or the theory of production. The only distinction is this: One deals with primary while the other deals with secondary production.

A large number of important studies are possible within the area of secondary production and the applicable analytical framework. These parallel the relationships of production studied in farm management and need not be repeated in detail here. Market

relationships need have little bearing on such studies. However, there is an important area in secondary production where the analytical framework is both one of production and one of market relationships. This situation holds true for monopoly, oligopoly, or other forms of imperfect competition. Here demand or supply curves are not only relationships of a particular market but are also those of a particular firm. Although Nicholls pioneered important and original work in this field, the field has not yet been fully exploited.⁶ Extended research is still needed in specific products and for specific firms. Microanalysis in the several areas of specialization should eventually aim at a general equilibrium analysis.

Income Distribution and Consumer Economics

Recent and current agricultural policies have been built largely upon distorted inferences surrounding aggregative quantities. The basic claim upon which agriculture has sought and obtained income transfers (under the guise of various storage, price, conservation, and other policies) has been the "aggregative" comparison of income per farm person with income per non-farm person. These broad averages are meaningless. There are many people on farms with incomes greater than those in other industries. The income of the wealthy farmer is supported, bolstered, and increased in magnitudes entirely out of line with welfare criteria and the public subsidy to the low income farmer or non-farm family. This comes about evidently because the public looks at composite farm and non-farm income ratios and therefore concludes that all farm people are "poor" and all non-farm people are "rich." For this and other reasons, research in income distribution and the pricing of factors is important. Here the crucial analysis should be in terms of particular individuals and groups and of the interrelationships of resource productivity, resource price and resource ownership. Analytical guides are not so clear cut here as in other important problem areas. However, the concepts of markets for factors and the marginal productivity of resources are steps toward formulating systematic analyses of personal income distribution.

A marriage which stands to be productive is that of studies in personal income distribution and consumer economics. The import

⁶ Nicholls, W. N., *Imperfect Competition in Agricultural Processing Industries*, Iowa State College Press.

of this joint relationship ranges from obvious individual problems to far-reaching public policies. The welfare justification of a price policy in agriculture depends partly, for example, on fashioning means whereby the consumption and diet of low income persons can be improved. Similarly, a storage program alone which stabilized production or the flow of product to the market may or may not increase total welfare, depending on how it affects individuals. One possibility is that the increment to total utility is greater under fluctuating supplies whereby low income groups can occasionally buy a quantity of the product than under schemes which stabilize prices and supplies out of reach of their incomes.

Welfare

All economic reorganization aimed at maximum social welfare must be couched ultimately in terms of particular economic units. The reasoning is obvious. Reorganizations are either one of two sorts: (1) those which make some individuals or groups better off only at a sacrifice of utility by other individuals, and (2) those that make some individuals better off without impairing the utility of others. An increase in total welfare is always guaranteed under the second. This is not true, however, in the first. The increment in utility to benefiting individuals may be greater than the decrement in utility to sacrificing persons. Policy could be based entirely on aggregative quantities only were it true that all individuals gain and none sacrifice as a result of public actions. This notion is entirely apart from reality, most economic reorganizations result in transfers between individuals. Occasionally, it is clear that transfers augment total welfare, but in most cases this is not true. Since inter-personal utility comparisons are impossible, an increase in total welfare can then be guaranteed only if compensation can be directed between the two groups so that the position of those with impaired incomes is no "worse off" than previously. Accordingly, policy can guarantee greater welfare only as it recognizes particular relationships and so gauges its course of action. Microeconomics will thus continue to be important and perhaps a crucial area of specialization and concentration.

IMPLICATIONS OF AGGREGATIVE THEORIES FOR AGRICULTURAL ECONOMISTS

SIDNEY HOOS
University of California

WAVES of fashion are not uncommon in economics. Each generation of economists seems to have its own "Holy Grail." The graduate student of today is exposed to and becomes saturated with concepts and relations unknown to his teachers in their days of graduate study. Nevertheless, there does exist a continuity in the development of economic thought. The historian of economic ideas can usually point to some earlier writer who at least had the "germ" of the so-called new approach. Today, a forefront of economics is immersed in that area which some call aggregative theories and others refer to as macroeconomics.

I

An early point to clarify concerns the essential differences between aggregative and particular equilibrium theories. A main difference is that particular equilibrium theories are concerned with the economic characteristics of individual consuming units, individual producing units or a particular industry. In contrast, aggregative theories deal with the economic system as a whole. Their object of analysis is the functioning of the economic system in totality, and the variables are values or functions of national totals or national averages.

Aggregative theories are a means of approaching, in a simplified but manageable way, some of the goals of the Walrasian general equilibrium. That system, as is well known, incorporates individual households and firms, as well as interrelations within the entire economy. Each separate economic unit is explicitly reflected, and each product has its own supply and demand functions which include also the prices of all other products. Conceptually, such a general equilibrium structure, if specified in adequate detail, can provide a means of determining equilibrium prices and quantities for the system as a whole as well as for the separate economic units within the system. To construct such a system, however, requires an extremely large number of equations to be solved in order to determine an equally large number of unknown values. Why Walrasian general equilibrium analysis has not proven useful

for practical purposes can well be appreciated.¹ To have a method of analysis which is manageable and provides a basis for making usable economic decisions concerning the economy as a whole, it is necessary to deal with aggregates and use aggregative theories. Such methods of economic analysis are often referred to as macroeconomics, in contrast with microeconomics which pertains to the behavior of individual economic units and for which particular equilibrium analysis is widely used.

It is quite clear that the current emphasis on macroeconomics stems from the profound impact of Keynes' *General Theory*.² Many earlier writers did think, analyze and write in terms of aggregates, but the analysis by Keynes of national employment and its determinants set the stage for the current emphasis (more than a fashion, I believe) in analyzing problems of employment, income and wages. Aggregative theories, however, are not limited to Keynesian or neo-Keynesian economics. Anti-Keynesians or "neutrals" have and do operate in an aggregative framework.

The recent and current emphasis on macroeconomics is, in part, a return to the general analytical methods of the classical economists and even their predecessors. The Physiocrats, Mercantilists, Smith, Ricardo, Malthus and their contemporaries were primarily interested in and worked with national economic aggregates.³ In their frame of reference, the individual firm and the individual consumer did not receive the analytical attention afforded them by later writers. Only beginning with the neoclassicists did the analysis of the individual consumer receive priority, and it was even later that

¹ A simplification of the Walrasian general equilibrium system in terms of industry aggregates has been developed theoretically and statistically by Leontief. See: Wassily Leontief, *The Structure of American Economy, 1919-1929* (Cambridge 1941); the following papers in the *Quarterly Journal of Economics*, Vol. 58 (February 1944), Vol. 60 (February 1946), Vol. 61 (November 1946); and "Recent Developments in the Study of Interindustrial Relations," *American Economic Review, Papers and Proceedings*, Vol. 39, May 1949, pp. 211-225.

² John Maynard Keynes, *The General Theory of Employment, Interest and Money*, (Harcourt, Brace and Co., New York, 1936).

³ Joseph A. Schumpeter, in "Keynes, the Economist (2)" (*The New Economics*, edited by Seymour Harris, Knopf, New York, 1947, Chap. IX) writes: "Richard Cantillon was the first, I think, to indicate a full-fledged schema of aggregative, monetary, and income analysis, the one worked out by Francois Quesnay in his *Tableau Economique*. Quesnay, then, is the true predecessor of Keynes."

The progress of aggregative analysis, before Keynes' *General Theory* but in recent years, is indicated in J. Tinbergen, "Annual Survey: Suggestions on Quantitative Business Cycle Theory," *Econometrica*, Vol. 3, No. 3, July 1935, pp. 241-308. On this point, also see; H. S. Ellis, "The State of the New Economics," *American Economic Review*, Vol. 39, No. 2, March 1949, pp. 465-477.

the individual firm became the object of intensive analysis. But beginning with Marshall, partial equilibrium theory became so entrenched that the recent emphasis on macroeconomics seemed to some an innovation rather than a resumption of an established method of analysis.

II

Those who have specialized in farm management or production economics of the individual farm have most clearly confined their interests to what is now termed microeconomics. But even there, interest developed in questions of aggregative behavior. In fact, some of the early notable work by agricultural economists grew out of the recognition by some farm management students that full appreciation of the adjustments faced by the individual farm required more knowledge about industry or group adjustments, and of the behavior of the economic system at large.

The study of supply-response in agricultural production broke away from the confines of the individual farm and became concerned with group adjustments. Interest had shifted from the individual producer to an aggregate of producers of similar products. The preoccupation of agricultural economists with statistical demand curves, beginning in the early 1920's and not yet abated, also may be cited as an example of our concern with national or aggregative economic relations, although limited usually to specific commodities.

The situation and outlook program, which had already been highly developed before World War II, was pitched at the level of particular agricultural industries. Although the Marshallian partial equilibrium apparently was the theoretical structure underlying the studies for the various farm products, some aggregative features were recognized since the outlook was framed with reference to the particular industry at large. But here an element of macroeconomics also appeared. A major factor affecting outlook was the level of national income which influenced the outlook for all industries. But national income or the general price level pertained to the economy as a whole. Thus, the situation and outlook analyses incorporated some macroeconomic variables within a particular equilibrium framework.

The preceding examples have been briefly cited only to recognize that agricultural economists have been aware of and have used

aggregates. But they have been primarily aggregates for particular industries, and thus the economic analysis used retained largely the features of particular equilibrium. The situation and outlook program, for instance, treated macrovariables as exogenous. Questions of economic relations between agricultural industries or between agriculture and the nonagricultural segment of the economy, or between macroeconomic variables for the economy at large, were not dealt with explicitly.

In the middle and the late 1920's, agricultural economists began to pay considerable attention to national agricultural policy. However, the theoretical treatment of policy questions was based largely on a microeconomic analysis. For example, the economic analyses of "two-price" plans, such as McNary-Haugen and Export-Debenture, incorporated the theory of price discrimination. The theory of price discrimination, however, is not in the real sense an aggregative theory; it grew out of and is logically still limited to the pure-monopoly individual firm. Only by imposing extra-economic (e.g., legal or administrative) constraints upon individual firms to give the group a semblance of an economic entity can price-discrimination theory be used as a rational explanation of multiple-price plans applied to agricultural industries composed of a large number of separate firms. A similar conclusion may be reached with respect to marketing agreements, the economic rationale of which is basically price-discrimination theory.

The use of microeconomics in analysis of multiple-price plans and marketing agreements assumes that the commodity or industry under consideration can be isolated, in terms of impact and interaction, from other commodities, industries or the rest of the economy. The validity of such an assumption is questionable, especially for major commodities. Even if the assumption is not too unrealistic for individual minor commodities, such programs for a substantial number of minor crops, operating at the same time, may have an aggregative effect different from that expected on the basis of a single crop program. One may wonder whether the instability of multiple-price programs or the meager success in evaluating their effects stems at least partly from the fact that they are based on a theoretical framework of microeconomic analysis rather than some type of aggregative theory which reflects relations of the particular industry to other industries and the economic system as a whole.

The development of the AAA parity-price and parity-income

program brought with it an emphasis on national aggregates. The agricultural sector of the economy, aggregated by some means into a single economic entity, was contrasted with the nonagricultural sector, which was also aggregated by some heroic procedure. The interrelation and interaction between the two sectors or aggregates and the impact on the total economy was presumably explainable in terms of some aggregative theory which, although implied, was not clearly formulated.⁴ One may wonder what specific economic theories underlie parity-price or parity-income programs. But one cannot deny that some type of an aggregative theory is appropriate; a theory which would include aggregate variables for the agricultural and nonagricultural sectors, and whose purpose would be to bring out clearly the effects of parity programs on income and employment in the nation as a whole as well as in the agricultural and nonagricultural spheres. It should be noted, of course, that serious problems exist in connection with the process of aggregation.

It is widely accepted that for an industry which is purely competitive in the purchase of productive services and the sale of product, the industry's short-run supply function is equivalent to the simple horizontal summation of the short-run marginal cost functions of all of the firms comprising the industry. This is a simple example of the process of aggregation. But that is not an aggregative theory; rather, it is only an aggregative process which yields one type of function from other functions. In order to have theoretical relations between aggregate variables similar to the relations which exist between the microeconomic variables, the aggregates must be constructed in an appropriate manner. Simple totals, averages or usual types of index numbers need not yield aggregates whose interrelations can validly be used as in a microeconomic theory. For example, on a given farm using a specified production function, the equilibrium utilization of the productive services is based on the proposition that the marginal value product of each service equals the marginal cost of the service. To make an analogous statement for a group of farms, the aggregate variables reflecting the group must be constructed and measured appropriately.

⁴ See Mordecai Ezekiel, and Louis H. Bean, "Economic Bases for the Agricultural Adjustment Act," U.S. Dept. of Agriculture (Washington, D.C., December 1933) for a widely distributed official statement; but in that publication the particular aggregative theory on which the argument is based is not sharply drawn.

Let us now return to the question of what bearing the aggregation process has on our use of economic theory. The conventional static marginal productivity theory of distribution may be considered as another example. Although such a theory may be questioned as to its realism in depicting individual firm behavior, its logical validity—as an internally consistent set of relations within the static framework—still stands. But what can we say about applying the marginal productivity theory to an industry or to the economy at large? Is the theory which is logically valid for the individual firm also valid for a sector of the economy without affecting some of the pertinent relations incorporated in the theory?

The outcome of several papers on this question indicates that the usual marginal productivity theory based on the individual firm cannot simply and at the same time validly be carried over in application to aggregates, and such procedure is even more invalid if the productive services are not homogeneous.⁵ Unless the analogies from microeconomics do occur among the aggregates, it would appear that basing our study of resource allocation in production or marketing, for agriculture as a whole, on marginal productivity analysis of aggregates (or simple averages) is of questionable validity.

The current emphasis on marketing research is spread over a wide range of marketing activities. In some quarters, interest is centered on the apparent temporal rigidity in marketing margins, their magnitude, and their relations to prices. These are questions the study of which cannot be successfully carried forward only by hypotheses drawn from the economic theory or behavior of the individual firm, since marketing margins also reflect group behavior

⁵ Some of the major references on this question are: F. W. Dresch, "Index Numbers and the General Economic Equilibrium," *Bulletin of the American Mathematical Society*, Vol. 44, February 1938, pp. 134-141; M. W. Reder, "An Alternative Interpretation of the Cobb-Douglas Function," *Econometrica*, July-October 1943; M. Bronfenbrenner, "Production Functions, Cobb-Douglas, Interfirm, Intrafirm," *Econometrica*, January 1944; J. Marschak and W. Andrews, "Random Simultaneous Equations and the Theory of Production," *Econometrica*, July-October 1944; L. R. Klein, "Macroeconomics and the Theory of Rational Behavior," *Econometrica*, April 1946; *idem*, "Remarks on the Theory of Aggregation," *Econometrica*, October 1946; Kenneth May, "The Aggregation Problem for a One-Industry Model," *Econometrica*, October 1946; Shou Shan Pu, "A Note on Macroeconomics," *Econometrica*, October 1946; Kenneth May, "Technological Change and Aggregation," *Econometrica*, January 1947; W. which affects the individual firms.⁶ Aggregative analyses are also called for, and dynamic rather than static theories are necessary.

III

Let us now turn to some general implications of aggregative theories for agricultural economists. Current discussions of employment and cycle theory are saturated with macroeconomic concepts such as savings, investment, multipliers and propensities. Regardless of what attitude one may take towards Keynes' formulation in his *General Theory* or the revisions and modifications by neo-Keynesians, it appears that aggregative analysis, which preceded Keynes, will also remain with the economic profession for some time to come after Keynes. This is likely not only because macroeconomic concepts and theories have a strong affinity to national policy problems, but also because microeconomics (e.g., Marshallian particular equilibrium) or Walrasian general equilibrium have not succeeded in providing concepts, tools, and theories which adequately deal in a usable manner with the type of problems handled by a simplified macroeconomic theory.

It would seem to me that it is important for agricultural economists to be at least familiar with methods of analysis and types of theory which in practice have and are very likely to continue to have an impact on national economic policy. Lack of sympathy with results of certain macroeconomic analyses, or disapproval of policy interpretations of certain macroeconomic theories, does not justify one's neglect of such theories. Contemporary developments in general economic thought are of significance to us as economists. We possibly could profit by seeking out from general macroeconomic studies those tools and elements that would be helpful in our own work.

It may be worth while to consider the development of aggregative

⁶ In this connection, the following statement is pertinent: "However, my main purpose is to identify a source of frustration in present marketing work. Most marketing research is concerned with efficiency. The frustration is the result of a problem in unit and interunit relationships in the field of distribution. Stated dogmatically, whatever inefficiency exists in marketing is rarely found in correctible form in the individual unit. The research worker thus comes, as he must, to the inefficiency of the complex of units that compose the market." This statement is from J. K. Galbraith, "Appraisal of Marketing Research," *American Economic Review, Papers and Proceedings*, Vol. 39, No. 3, May 1949, pp. 415-416. If "the inefficiency of the complex of units that compose the market" cannot be corrected at the individual unit level, an alternative is the evaluation of correctives applied to the aggregate; such evaluation would involve aggregative theories.

theories applicable to agriculture and which fit into macroeconomic theories concerning the economy at large. With the use of aggregates, and in terms of macroeconomics, Keynes claimed to have developed a logical explanation of the existence of macroequilibrium at less than full employment. This is a result at variance with neoclassical doctrine, but a result which had a marked stimulus on current thought. Hence, if there exists chronic unemployment in the agricultural sector of our economy, might it not be explained by some aggregative theory applicable to agriculture and which is consistent with a national macroeconomic theory? Usually, explanations of the existence of unemployment in agriculture are presented in terms of rigidities, frictions, and institutional influences, which undoubtedly are relevant, but they certainly do not comprise a theory.

The advantages of working with an appropriately constructed aggregative or macroeconomic framework should not be slighted. One advantage we have already touched upon. Relations or attributes of individual firms or consumers, or even of small groups of firms or consumers, need not be valid for the economy or large groups. The possibility of interaction within the group may give it a character different from that of each of its many components. Also, at the same time, we can often say more about the characteristics and behavior of an aggregate and predict more reliably its behavior than we can for the individual firms or consumers composing the group. The behavior of the aggregate is more stable than the behavior of the separate individuals. Hence, we have a better basis for the study of empirical relations and derivation of statistical uniformities. With respect to agricultural production-adjustments, marketing, and consumption, there may be group-behavior characteristics waiting to be discovered, the knowledge of which would contribute to our understanding of the agricultural economy and its interrelations with the nonagricultural sectors.

Some introductory work along this line has been done in sketches of behavior characteristics of the aggregate agricultural sector contrasted with the nonagricultural sector of the economy.⁷ Such

Schultz, "How Efficient is American Agriculture?" this *Journal*, Vol. 29, No. 3, August 1947, pp. 644-658, *idem* "The Economic Stability of American Agriculture," this *Journal*, Vol. 29, No. 4, Pt. 1, November 1947, pp. 809-826; Walter W. Wilcox, "The Efficiency and Stability of American Agriculture," this *Journal*, Vol. 30, No. 3, August 1948, pp. 411-421. Also, see: Trygve Haavelmo, "Quantitative Research in Agricultural Economics: The Interdependence between Agriculture and the National Economy," this *Journal*, Vol. 29, No. 4, Pt. 1, November 1947, pp. 910-924.

sketches, and inferences drawn from them, may be viewed as elements in a macroeconomic model which explicitly includes as variables functional relations within as well as between the agricultural and nonagricultural sectors. In this type of analysis, we approach macroeconomic theories which may adequately account for, in a useful way, the working of the national economy and agriculture's position in it.

The use of aggregative concepts has been criticized on the grounds that such procedure neglects the more important economic entities such as the individual consumer or individual firms. Some economists, for example, have attacked the Keynesian system for not explicitly recognizing the influence of the distribution of income. The criticism, I believe, is valid. But although the Keynesian structure does not directly incorporate income distribution as a variable, it does not follow that all macroeconomic theories need to exhibit a similar neglect. As macrotheories develop and as more variables are included, significant elements such as income distribution can be introduced. It may be noted, however, that burdening macroeconomic theories with too many variables will dissipate a major advantage of macroeconomics, mainly simplicity and manageability.

The simplicity of macroeconomic theories has been the subject of frequent criticism; it has been asserted that the models are so simple that they lose all semblance to reality. But such simplicity, if it is fully recognized, may well aid rather than handicap the analysis of economic relationships. Here, as in microeconomics, the danger lies not in the simplicity itself, but in the mistaken identification of the simple model with the complicated structure in which we are basically interested. The over-simple characteristics of a macroeconomic model are relatively easy to recognize and to bear in mind; whereas in the usual microeconomic analysis of the individual firm, for example, there has been a strong tendency to substitute the elementary model and its assumptions for the complexities of economic reality. A case in point is the marginal cost-marginal revenue explanation of short-run price and output determination by the individual firm.⁸

⁸ Of the substantial number of papers participating in the marginal-pricing controversy, the following may be cited. R. L. Hall and C. J. Hitch, "Price Theory and Business Behavior," *Oxford Economic Papers*, No. 2 (1939). R. A. Lester, "Shortcomings of Marginal Analyses for Wage-Employment Problems," *American Economic Review*, Vol. 36 (March 1946), *idem* "Marginalism, Minimum Wages, and Labor Markets," *American Economic Review*, Vol. 37 (March 1947); "Equilibrium of

An essential question is whether we can deduce useful generalizations from aggregative theories which cannot be learned from microeconomics. The answer appears definitely to be in the affirmative. This has long been recognized in business cycle theory. Regardless of the detail to which the theory of the individual firm or household is carried, whether it be a dynamic or static theory, it cannot explain, in a manner useful for making practical decisions, the levels and movement of employment, income, savings, investment for the economy as a whole nor variables such as "the" rate of interest. To study such important problems, and in our society they are of prime significance, our practical recourse is to the use of aggregates and analyses in terms of macroeconomics.

In connection with agricultural policy, the importance of national income and employment levels to agricultural prosperity is now widely recognized. The notion that national income can be advanced, in a permanent way, by special farm programs, no longer has the acceptance it received a few years ago. Now, most students lean toward the idea that, "High-level employment in non-agricultural industry means very much more to farmers than any 'farm-program' the government may attempt."⁹ This view leads us to the thought that macroeconomics is the appropriate framework in which to deal with some important aspects of the so-called "farm problem."

The "farm problem" might well in large part, though not entirely, disappear in the face of an over-all national economic policy which provides a relatively stable and high level of aggregate employment and income. Some farm programs involve the flow of government funds directly to particular agricultural producers or industries. But such programs are difficult to justify, from the national viewpoint, unless it can be demonstrated that injections of purchasing

power into agriculture have a greater multiplier effect and a more desirable distribution effect on aggregate income, than money injections into other groups in our economy.¹⁰ To my knowledge, such a demonstration has not been provided.

Since the macroeconomic theories proposed in recent years were developed to deal with the level of aggregates as employment, income, or investment, such theories throw little light upon the question of resource allocation. But that is a question which has attracted the attention of agricultural economists, especially in connection with the formulation and appraisal of agricultural programs. The distribution of employment between agricultural and nonagricultural pursuits, for instance, or relative wage rates in the two spheres, or relative prices of farm and other products, or relative costs and returns in the agricultural and nonagricultural sectors are relations pertinent to agricultural policy. Such questions and others related to the problem of resource allocation receive little aid from presently available macroeconomic theories. It would therefore appear that there is need for macroeconomic theories for analyzing questions of resource allocation. Such macroeconomic theories might prove more enlightening than a marginal productivity framework now usually used in the analysis of resource allocation.

IV

The preceding comments are not meant to imply that microeconomic analysis is obsolete and can serve no useful purpose in agricultural economics research or program-policy formation. On the contrary, it seems to me that as macroeconomics matures, and as we advance from a skeleton of macroanalysis to full-bodied macrotheories, it becomes equally pertinent that our tools of microanalysis and particular equilibrium be improved.

Economic problems in agriculture are so vast, complicated and varied in character that no one single approach will induce a complete understanding. For certain problems and questions, the knowledge of microbehavior is necessary, and in the study of such problems microeconomics remains the appropriate approach. Macroeconomics and microeconomics are not competitive approaches to

¹⁰ A somewhat similar point is made in Report of a Committee, "On the Redefinition of Parity Price and Parity Income," *This Journal*, Vol 29 (No. 4, Part II) November 1947, pp 1353-77.

the analysis of economic phenomena; rather, they are complementary and consistent with each other. Microeconomics and macroeconomics supplement each other in a manner as firm analyses and industry analysis or as the short run and long run are complementary.

But many significant economic problems are not wholly within a macroframework nor wholly within a microframework. Many problems lie largely within a penumbra which is bordered by both the micro and macrotechniques. Hence, a bridge is required so that we can easily transfer from one approach to the other. To accomplish such an objective, a really general theory, of which both macroeconomics and microeconomics are special cases, is required. But it should be sufficiently simple and so constructed that usable decision-making hypotheses can be stated and accepted or rejected by empirical tests. Such a general theory would not only bridge the present gap between micro and macroeconomics, but might also suggest paths of action from national policy to programs in particular industries and adjustments by particular firms.

USE OF ECONOMICS IN FARMING

TRUE D. MORSE

Doane Agricultural Service, Inc.

THIS is a joint meeting of Farm Economists and Farm Managers to discuss "Farm Management as an Art." The title implies a degree of management ability applied to farming that is above the ordinary—ability that goes beyond the mere application of rules and standard methods. Certainly, farm management cannot be lifted to the level of an art without unlimited use of economics.

This fact stands out with increasing vividness as farming becomes more commercialized and as the government takes an increasing part in managing farms and agriculture.

Production methods and techniques are successfully applied to individual farms by increasing numbers of farmers and farm managers. The response of the different soils to various treatments can be determined from published experimental data and verified by use on the farm. Methods of plowing, planting and cultivating are well known, and with modern machinery, can be repeated with an increasing degree of precision. Seed of known quality can be purchased. Chicks and poults are purchased according to standard specifications, brooded under precision machines and grown with feed of known quality. Livestock breeding and feeding is done with more and more knowledge that certain practices produce specific results—the range of variability is being constantly narrowed.

This increasing control of production has been greatly moved forward by the commercialization of agriculture. Many of the most difficult jobs are now done by specialists working for large companies that standardize their products. The production of hybrid seed corn, chicks and poults are examples. The mixing of feeds, fertilizers and pest control materials are commercial operations. Commercialization has certainly made a major contribution in stepping up production control on farms by providing efficient machines and equipment.

Dr. O. R. Johnson, head of the Economics Department of the Missouri College of Agriculture, in addressing Farm Managers last fall, told them—"...land itself resembles more and more an empty factory building like Willow Run before Kaiser-Frazer moved in. What the farm operator does in the space provided is

becoming much more significant than any inherent qualities which that space may possess."

The production side of farming deals largely with tangibles. In contrast to this, the economics end of the business deals with intangibles that cannot be nailed down into definite formulas or carried through with precision machines and equipment. Economic forces controlling prices may be cut across any day or any hour by local, national or world events. All calculations of a farm manager may be changed by a new law or an administrative decision of a governmental official or board. As compared with the production part of his job, farmers and farm managers continue to swim in a sea of economic uncertainty.

This does not mean that progress in the field of economics has been less than in production. These facts are set forth to show the great need of farmers and farm managers for economics. This need extends far beyond their own abilities and the resources available to them on the farms or through their organizations.

It is in recognition of this fact that state universities and the U.S. Department of Agriculture have developed agricultural economics departments. Farm organizations have their economists. Financial and commercial firms supplying farmers with services and supplies are more and more attempting to provide economic guidance to farmers and farm managers. They need all the help they can get—much more specific and timely advice than they are now receiving.

Note in that last sentence, I used two words of importance—"specific" and "timely." This entire paper could well be used to discuss either. Too many economists are either so uncertain of their judgment and information or so unwilling to risk their professional standing that they fail to be sufficiently specific to be of great help to farmers and farm managers.

Farm operations must be projected long months ahead. Too much economic information is both "too little and too late." Farmers are making their decisions now on buying feeder cattle and lambs to be sold in 1950. Last April and May, they were breeding the sows to get pigs to sell in 1950. The outlook conferences and publications for 1950 will be issued after many of these decisions have been made. This fall, farmers, ranchmen and dairy farmers will be saving back or buying cows and heifers for beef or milk, based on returns they expect to get during the next three years or

more. How much specific advice do they have now to help them make these vital decisions?

With these broad statements as a background, let's look briefly at some of the economic developments that indicate how farmers and farm managers will be using economics in farming.

Industrial production and business trends outside the field of agriculture are known by every competent farm manager to be of vital importance to his success. Demand for various farm products goes far in determining whether prices of the products he is producing will be profitable or not. Farm managers and the most alert farmers are therefore hungry for those expressions of judgments regarding longer time industrial and employment trends that some economists are now issuing. Right or wrong, they want to know what the most competent economists see ahead. The individual farmer and farm manager has little basis for forming a judgment of his own.

Too much that is being said for the press or on the radio is unfortunately tinged with propaganda. For example, some high officials treat citizens like children, "for fear of talking the country into a depression," and put out half-truths and only part of the facts. Farmers and small businessmen go forward half blind to the true situation. That can lead to disastrous management mistakes.

The population is rapidly growing. We are 10 years ahead of schedule on population growth and we are adding over one million people per year. Farm managers are watching not only the total population numbers, but the relative proportions of youth and old people in trying to gear their production to the diets of the people.

The productive capacity of our farmers has moved ahead at a rapid rate. With normal weather, they can feed all the people, regardless of the rapid population growth. Production is running over 30 percent above pre-war, and it will continue at a high level. A new all-time high in crop production was set last year. This will be another record or near-record crop production year.

You know the effect of mechanization, improved seeds and more efficient feeding. Now the use of chemicals holds the possibility of greatly expanding farm production. The growing use of fertilizers is also a major factor. Farmers have been given a liberal education in the use of fertilizers as they have profitably used them during and following the war period.

Alert farm managers know they are in an efficiency race. They

must drive down costs and increase quality. Only the most capable farmers will survive with a decent standard of living.

It now takes cash to farm. Self sufficient farming is gone from commercial farms. For almost every operation cash costs are involved. Will farmers continue to produce when prices drop? Or will they let tractors stay in the shed and land lay idle? Will we shut down farms like factories shut down when the selling price of crops goes below costs?

Farmers never have closed down—will they in the future? I expect to see that happen—idle land and idle equipment.

The impact of the foregoing facts will be most acute in cash crop production areas like the wheat lands of the Great Plains. When either drouth or price prospects indicate that cash production costs will not be returned, farmers and farm managers will shut down their farming or cut production until more favorable conditions return.

The break-even point in farming is higher, much higher than before the war. Even the drops in prices that have already taken place will put many farmers in the red.

Dr. Sherman E. Johnson, when Head of Farm Management in B.A.E. in Washington, was concerned over this development. 1948, "... was the first year in a decade that gross income failed to rise more than costs. Consequently, farmers can't reduce their cash outlays during a price squeeze in the same way that they did formerly. Today, fuel and oil and repairs for the farm tractor are out-of-pocket expenses. A larger share of family living costs also are cash expenses. Most farms now have electricity, and fuel for the farm furnace is delivered by the oil man or the coal dealer rather than being cut from the farm woodlot. Farm real estate taxes . . . have been rising for four consecutive years.

"... the young man who is getting started in farming will have to invest two or three times as much for land, equipment, livestock and supplies as before the war . . . heavy debt on such an investment could be an unbearable burden."

In the present declining phase of the economy, every alert farmer and farm manager should be refiguring his individual farm enterprises as well as his total farm business to establish in advance the probable break-even points. All the specific help that economists can give regarding future prices and costs will be useful farm management tools.

Flexible farming is being advocated. Iowa State College says, "The puzzle of uncertain prices is still with us. . . . Today, more than ever, it is smart farming to keep your business flexible—flexibility and short-term production methods can be combined even in construction of farm buildings."

We are saying to farmers—Keep your operations pliable. Avoid being caught in a profit squeeze due to a rigid pattern of operation that cannot be varied sufficiently to meet shifting conditions. Changes in crop production and carry-over; increases or decreases in the number of hogs, poultry, cattle and sheep; shifts in consumer demand and exports; AND changing government laws, rules and regulations are just some of the reasons why there should be flexibility in your farm program.

Have a basic plan of operation adapted to your farm, ranch or plantation. But, be sure flexibility is provided for in the plan. One very important reason for flexible farming is that governmental regulations lag behind the need for action six months or more. There will be these periods of serious maladjustment in prices and regulations regardless of the political party in power.

Increasing specialization in farming enables farmers and farm managers to become more keen students of economics for the products which they produce. As a result, they will cut back and expand production much more freely than in the past.

As I have already pointed out—the old days of production, regardless of price, may be over for some commercial farmers. Cash costs of farming—with the use of economic facts and forecasts—may cause specialized farms to expand or contract production like industrialists have always done in factory operations.

Price and production controls by the government, of course, will become increasingly dominant. In many cases in the future, price "floors" will become top prices. Floors will become ceilings. Too many small producers will find themselves subject to discounts or prices below those set by the government, as enforcement breaks down or price regulations are avoided.

Profits or losses in the years ahead will be strongly controlled by forces operating beyond the control of farmers and outside the boundaries of the farm. Washington legislators and officials will continue to conceive "Bold New Programs" and move closer to a welfare state. Farmers and farm managers must go beyond economics and try to out-guess political strategy and maneuvers. Re-

ardless of the political party in control, there will continue to be a high degree of uncertainty about what the government will do, and when.

For example, who would have expected turkey growers to be bailed out with good profits with a 31-cent price support after they disregarded all government forecasts and warnings showing the over-expansion in turkeys that was taking place this year?

An example of price discounts was seen in the excessive cuts made in the price of wheat for moisture and such impurities as garlic.

For several years, alert farm managers have been jockeying for a favorable acreage allotment when controls return to high profit crops. They have, of course, been kept almost completely in the dark about what would probably be the basis of allotments.

Rules of thumb are sorely needed by farmers to guide them in management decisions. They should be brief and to the point. Farmers use a lot of them now, but they need to be brought up-to-date and extended by economists, who are in a better position to make them than anyone else.

The old 10 to 1 for corn and hog prices is still in use. Few farmers know, in such simple terms, what efficient producers can expect.

Dr. Stanley Warren of Cornell University has a rough guide, which he gives his appraisal classes, of \$400 to cover the farm investment per dairy cow.

There is evidence in some ranch areas that the real estate investment must be held to about \$150 per cow for practical operations.

We say that animals can afford buildings that cost about as much as the annual gross income per producing female. There are variations such as \$250 buildings for \$200 annual income dairy cows.

How much price increase must you get before you can afford to store wheat, corn, oats, soybeans or cotton?

Such economic guides, quick and easy to use, even though often crude, are invaluable tools that more farmers need to be using in the management of their business.

Farm management must be lifted to the level of an "Art" by those farmers and professional managers who will be successful in the difficult days ahead. Only those who use dependable economic guidance can be assured of profits.

Most farmers and farm managers have neither the background nor the time to master and keep up with the economic information which they need. They must increasingly look to economists who regularly get farm dirt and manure on their shoes to understand the management needs of farmers, and who get the economic advice to them in simple, easy-to-understand terms. The advice must be in their hands when needed, and be specific.

With such aid from economists, able managers of farms will then decide what action to take. Able managers know that economists cannot always be right when they draw conclusions regarding the future—but they want their best judgments. Otherwise, they are blindly managing insofar as much of the economics applying to their farms are concerned.

THE MISSOURI PLAN (BALANCED FARMING)

J. W. BURCH

University of Missouri

THE Missouri Extension Service taught individual farm practices, as did all state colleges, until 15 years ago when the need became apparent for a system of farming that would tie together all of the good practices recommended by the college for a farm in a way to give the greatest net income consistent with continuing improvement of the soil. Throughout the years certain farmers have specialized in beef cattle production and perhaps failed to improve their pastures, and others specializing in crop production failed to receive high net income because of poor feeding practices. The college, with its traditional 12 to 14 departments and Extension specialists for each, undertook to save the farmer by teaching the individual practices, leaving it to the county agent or the farmer to tie these practices together, if any attempt along that line was made.

This idea of developing a system of farming, called in many states Farm and Home Planning, is called Balanced Farming in Missouri. The objective has been to achieve a balance between input and outgo of soil fertility; between type of soil and crops; between pasture and crops and the livestock system; between the livestock system and the desires and abilities of the operator and his labor supply; between net income and the needs of the farm family; between good planning, hard work and a comfortable, attractive home.

The Balanced Farming program has been handled largely by a committee of specialists and supervisors, with a soils specialist as chairman. The program does not belong to the farm management or any other department. Each specialist has an opportunity to push his line of work to the limit but does so in cooperation with other specialists in developing systems of farming. The dairy specialist has come to recognize that the dairy farmer will not succeed unless the soil is improved to enable an abundance of good feed to be grown for low cost production. Crops and soils specialists recognize that improving the soil and growing an abundance of feed is of no avail unless there is good livestock management to get the most dollars out of the increased feed production.

Back in 1936, 22 specialists and supervisors spent four days in

teams of four men, each planning farms and arguing over the plans. Since practically every specialist had been a successful county agent, it was not long until the poultry specialist knew how to lay out a good water management system; not that he expected to do that, but in order that when he talked to county agents and farmers about new poultry practices his recommendations would fit into an over-all plan that took care of erosion as well as raising healthy pullets. The swine specialist quickly recognized that preaching hog sanitation is a futile gesture unless there is a system developed on the farm whereby there will be at least three fields as a minor rotation of corn, small grain, and clover. This provides good pasture and clean ground. Each field must be fenced hog tight and provision must be made at the outset for water in each. Whereas our service preached hog sanitation for years prior to Balanced Farming, our results were very scanty; but now with Balanced Farming we help the farmer plan for hog sanitation so that it is the easy and natural thing for him to do with his hogs.

Naturally, in the early days of Balanced Farming, we started by means of demonstrations, schools, and all the traditional Extension methods. One concept has been held to throughout the years. It must be the farmer's own plan. Even though it takes much longer for the county agent or associate agent to stay with that farm family until they think through what they want to do and why, than it would for the agent to plan the farm, it's the only way to do it if we expect the farmer to do anything about the plan that is made. Changing economic conditions mean that plans must be changed. Therefore if the farmer does not help make his plan he does not know how to change it when he should. He will simply lay up his paper plan on the mantle by the clock and let it gather dust.

I do not think it necessary to go into detail with this group as to how a county agent and the farmer work out the plan. It must be remembered that in our state we have freezing and thawing throughout the winter, with torrential rains through the spring and fall, and are subject to drought in late summer. In addition, most of our state is quite rolling, all of which means we have a terrific erosion problem. No farm plan is complete without a water management system that will provide terraces for at least all fields that are to be used for row crops. We have four Extension agricultural engineers whose job it is to see to it that all county agents, associates, and assistants, have the latest information and

skills on water management with which to assist their farmers. This means of course that it is more difficult in our state to develop farm plans than it is in the states north, east, and west of us which do not have this tremendous erosion problem. What I mean to say is that if Missouri can develop farm and home plans, as it has, there is no reason why other states, with the possible exception of our neighbors to the South, could not do so more easily. While water management is fundamental, our agents start a farmer wherever his interest is greatest. If he is a dairyman, they get him started in the cow test association, in the artificial insemination set-up, with a real dairy feeding, breeding, and selection plan, then lead him on to the needs for better pastures and more feed, showing how soil fertility must be improved to get the extra feed, and how foolish it would be to lime and fertilize soil and then let it wash off.

I trust I have made it clear that Balanced Farming is much more than a soil conservation plan. Balanced Farming gets soil conservation but it gets the highest net income possible first and gets soil conservation as a by-product. There is not necessarily any direct connection between a plan that will give soil conservation and one that will give high income. A farm could be seeded down to timothy and it would save the soil, but the family would starve to death. On the other hand, you cannot have a successful long time Balanced Farming plan, unless the soil productivity balance is increasing. We have simple formulas in our workbook so that each farmer can test this for himself.

To be specific, Waldo Woolf of Warren County, Missouri, had a thin 160 acres that would produce feed enough to carry 10 dairy cows. With his county agent he developed his Balanced Farm plan and by the use of lime and fertilizer, clover, better pasture systems, and a water management plan, six years later the same farm fed 22 dairy cows much better. At the outset of the plan the 10 cows produced slightly over 200 pounds of butterfat per cow. Careful planning and selection of the best heifers, culling out of the poor producers along with a real feeding program, meant that at the end of the six year period the 22 cows had moved from slightly over 200 pounds of butterfat per cow to 419 pounds. That, in a word, is Balanced Farming—moving from 10 cows producing 200 pounds of butterfat per cow to 22 cows producing 419 pounds of butterfat per cow. I need not tell you that quadrupling the gross income means much more than that in terms of net income.

Then there was the Robert Jennings family of Lawrence County, whose 120 acres in 1943 supported 14 mature cows when they started their Balanced Farming plan. By 1947 this farm carried 21 mature cows with 12 heifers. They went from 50,800 pounds of milk in 1943 to 109,000 pounds in 1947. By soil and crop improvement they raised the carrying capacity of the farm 50 percent but at the same time by good herd management they raised the milk per cow from 4200 pounds to 7200. In 1943 they used 2500 pounds of fertilizer, in 1947 they used 9400 pounds; in 1943 they used 12 tons of lime, and in 1947 they used 43 tons. In 1943 they had no terraces, by 1947 they had practically two miles of terraces built or in the process of being built, with three quarters of a mile of terrace outlets ready to receive water from additional terraces. Using 1947 prices, their gross farm income in 1943 would have been \$3386 and by 1947 this was increased to \$7380. Their net farm income rose from \$2390 to \$4632.

Bob Maledy of Dent County, one of our Ozark counties, with his Balanced Farming plan through better pastures and better herd management increased the weight at weaning time, on beef calves, 90 pounds per head. His neighbor, Henry Meyer, with 21 beef cows produced 21 calves which at an average age of 262 days had an average weight of 604.2 pounds. When 8½ month old calves weigh better than 600 pounds on the average, you are getting beef produced and that is what Balanced Farming will do. Back in the late '30's before war prices, Charlie Schaefer of Lafayette County, with his Balanced Farming plan moved in 5 years from a 15 cow beef herd to a 40 cow beef herd and his net income from \$1150 to \$2266.

Tom Ream of Pettis County, with his Balanced Farming plan, was able to save one more pig per litter with his pigs on clean ground and to market them weighing 225 lbs. each a month sooner than he had prior to using the plan. His neighbor with a secondary rotation of three 10 acre fields, one with clean clover pasture for his hogs, was able to make each 100 pounds gain with four bushels of corn and 15 pounds of tankage, in addition to the clover. That means net profit in anybody's language. The alternate poultry yard and farm garden has meant much to our farmers. The ½-acre field that was the poultry run last year is the garden this year. Last year's garden is clean ground for this year's pullets.

We have made lots of mistakes in the development of our pro-

gram and one of them was to assume that it would be better to start the agricultural part of Balanced Farming first and bring in the home side later. We are now making every attempt to rectify that mistake. The object of Balanced Farm planning is better farm family living. Therefore, we start today figuring what the family needs in the way of income to buy the things they need. If the old plan doesn't produce this necessary income then a different plan obviously must be worked out. Small farms naturally must go into intensive systems of farming. If the operator doesn't like intensive systems then it is now clear to him that if he is to have a decent living, he must have more land or change to intensive farming.

I spent last Thursday in Osage County, Missouri, where 10,000 farm people gathered at a Balanced Farming Action Day in what is known as Deer Creek Valley, where five adjacent farms have complete Balanced Farming plans in operation. It was a wonderful sight to see the farm homes with all the labor saving devices that had been developed since they started Balanced Farming. Of the 300 farm families now doing Balanced Farming in this little border Ozark county, over one-third have built new homes or remodeled the old ones. Their plan provides the family a high plane of living, electricity, water under pressure in the home, a kitchen sink, bathroom, and plans for health and educational needs. I mention this since we recognize now that farmers must necessarily move slowly as funds will permit in making the home improvements. It is therefore absolutely essential that a plan be developed as to when these things will be done. Otherwise, less important things will take the funds, the farm woman will become prematurely old, and the youngsters lose their interest in the farm. I wish again to point out that, important as improving the soil may be, more important is the health, happiness, and well-being of the farm family. And I have no hesitation in saying to this group that those of you who believe that income alone will bring satisfactory farm living are terribly wrong. It takes careful planning that must be tied in with the over-all plans for the farm. We have tried it both ways. It works when the two are tied together; it doesn't work when they are not. We want the farm woman in Missouri to help with every step in the farm plan and her husband to help with every step in the home plan. This also goes for the older children. It must be a family approach. This calls for real teamwork if it is going to succeed, at least in a state with the type of restricted resources that Missouri has.

This was well illustrated in two Balanced Farm planning schools that were held for county agents and home agents in South Missouri some years back. At the first school the county agents worked together on developing a practice farm plan on an actual farm while home agents worked on the home plan for the farm. Then each group presented their plan for the other's consideration. When the home agents presented the cost of home improvements needed, the county agents whistled. They had not seen the need and they had not anticipated such expenditures in their plan for farm operations.

Two years later a similar school was held with many of the same agents attending, but this time county agents and home agents worked together in groups to obtain an understanding of all phases of this farm and home planning job. This time when various groups of agents presented the plans they had developed there was no whistling, even though costs for home improvements were larger than before. The men agents knew the needs of that farm home and the women agents knew the income producing possibilities of the farm, and since both had worked together a very important balance has been reached—a balance between the farm and the home. And of course the importance of this family approach is not lessened when it is the farmer and his wife and older children working together on the plan.

We know that we can move production up on the average of 25 to 75 percent by Balanced Farm planning. Our problem is, how can we move more rapidly—how can we interest more farmers? We have 114 counties in our state and we have Balanced Farming work going in every county. However, in 1946 we started in one county with what we call a Balanced Farming Association. Fifty farm families banded together, paid in \$50 each, the businessmen of the community put in \$1250 and the Extension Service put in \$1250 to provide a \$5000 fund with which to hire an associate agent to help these 50 farm families set up Balanced Farming plans. This has been the most helpful device we have found to move sound farm and home planning. In 1947 we had 17 of these associations, in 1948 we had 29, this year we have 37, next year we will have 46. This would represent 45 different counties—one county has two associations. This growth testifies to the effectiveness of this method.

When a farm family puts in their own money to help employ an associate agent who in turn helps them develop a farm and home

plan they are ready to move. People value things that they pay for with money or in work. The things that are given them are not valued so highly. This, I think, accounts for the fact that it is in these associations that we have made real progress in Balanced Farming. Take for example, Lafayette County. They had two Balanced Farming associations in 1948. The county built 269 miles of terraces. The 20 county soil districts in our state built a total of 520 miles of terraces in 1948 according to the SCS reports. Among the 114 counties in the state using nine measures of soil conservation, Lafayette County ranked first in three of them. It was first in miles of terraces built, first in acres contoured, first in terrace outlets built, 6th in tons of limestone used, 7th in number of farms contoured, 10th in number of ponds built, 11th in total acres of sweet clover, 12th in acres of green manure turned under and 15th in tons of fertilizer used. I simply use this as an example to indicate that there is correlation in our state between the progress in conservation, in soil improvement, and in the number of these associations a county has. It is also interesting that in 1946, the same county that first started a Balanced Farming Association started our first soil testing laboratory. Today we have 60 county soil testing labs where a farmer can learn from his own county agent the kind and amounts of fertilizer needed for each of his fields. This is a tremendously significant development and is another by-product of our Balanced Farming program—to help people to help themselves. In the four years since we have started these labs we have increased fertilizer use 50 percent. Missouri is today using 10 times as much fertilizer as it did 10 years ago.

Certainly we have had our ups and downs with these associations. Some have failed, principally because we did not have men available of the type essential to make a success of one of these associations. It takes the very highest type of a county agent. He must be able physically, as well as knowing farming from the ground up, to handle this job. We have 38 of them on the job today and as I said a minute ago, expect to have 46 on the job next year. As the years go by, however, we are going to have the best trained bunch of county agents anybody has ever seen, since it takes real men to do this job. This associate county agent turns first to his county agent and home agent when he hits a hard problem. He is not a superman. If they still have trouble, they have first call on our specialist group for we believe that we have men who, in their

respective fields, know the answers better for the state of Missouri, in water management, farm management, soils, field crops, dairying, animal husbandry, etc., than can be found anyplace else. It is their job to keep these county workers sound. It has been a tremendous challenge to our specialists. They have responded in a magnificent way. As our soils specialist, the chairman of our Balanced Farming committee puts it, "Let's quit fooling with these darn meetings and get out on the farm and get something done."

The essential philosophy in this Balanced Farming approach is that the welfare of the farm family comes first, that you will never improve and conserve the soil unless farmers determine to do it themselves largely with their own resources; that it is just as essential to have a blueprint for the improvement of the farm and home as it is to have one with which to build a barn or a house.

There is one thing of which we are certain and that is that we do not have the final answer. We are convinced that our present methods are effective, but we wonder whether there are not still better ways of getting the job done. We are experimenting right now with a number of different ways of doing farm and home planning. In one county, for example, we are trying out a somewhat less intensive method of planning. The agents in a single year have 85 farms well under way. These are in separate school districts and we expect to try within another year an experiment to see how much we can do in using these 85 men as local leaders who would be willing to help a half-dozen neighbors in setting up their Balanced Farming plans. We are experimenting with this in the hopes that some day the government might recognize that you could put on a great voluntary program of farm planning where you could really get soil conservation and get it paid for at the same time; where you could get real crop adjustment through mass farm planning. It is perhaps wishful thinking that a thing so inexpensive and so simple could ever be incorporated in an over-all farm program. But we know we could make it work in Missouri, so we go on working and hoping that we might have this chance, because with it or without it, we know we are doing one hundred times better Extension work today, getting more practices adopted every year than we ever dreamed of getting before we started with the Balanced Farming approach.

Among the things that we have learned is that to have progress in a venture of this kind facilities must be available. Among those

facilities, I would include farm management companies who will work with the larger farms, the non-resident owner farms, and the farms that would require the close farm management attention that our county agents cannot, or at least should not, give. In our state we have 325 soil moving contractors. They have their own contractors' association, many of which men are former county agents. They have put their money in machinery to build terraces, soil saving dams, ponds, drainage ditches, and that sort of thing. They have the know-how, they can do the work much better than the farmer can do it for himself, and in general we believe it will pay a farmer to hire one of these men and use his own time in developing his livestock enterprise or other things on the farm that will bring in the money with which to pay his contractor. Fertilizer dealers have been a great help in our whole program. In turn we are asking them to stock the kind of fertilizer farmers should have and they are doing it. We must include businessmen in a program of this kind. Our businessmen, particularly our State Bankers Association, help support the Balanced Farming associations. Again, when a man puts his own money into a thing he is proud of it. He talks about it. He boosts it, and all of this helps carry the program. We believe the development of Balanced Farming around any agricultural town helps more than the bringing in of any type of factory or anything of that sort that they could possibly find. Why not allow them the privilege of investing in a really sound development program? Incidentally, we have more difficulty in selling our farmers on this idea of allowing the businessmen to help finance an association than we do the businessmen.

All in all, we believe that the development of the Balanced Farming program has been one of the great things that has happened in our state. We were barely started when the war years took away our younger county agents and pretty well stopped our program. Since the war we are getting under way again and have more than 20,000 farm families in some stage of a Balanced Farming program. It takes years of hard work for a farm family to get a really good program under way. It takes the constant encouragement of the county agents to keep them working at the plan once it is made.

We look forward to the day when a couple of hundred of what we call "graduates" of our Balanced Farming associations may form a more extensive type of association in a county and pay all of the salary of their associate county agent, a man with particular train-

ing in Agricultural Economics, who will not only help keep them on their plan but help them really use outlook information. Such an association would work in groups more than is possible or necessary with the small associations when the individual plan is being developed and started.

As I stated before, we do not know all the answers or any considerable number of them about getting farm and home planning done; but we do think it is the soundest and most fundamental approach, both from the standpoint of the farm family and from the standpoint of the Extensive Service, that we have ever had. With the advice of our farm people we expect to keep on improving our techniques until some day you can ride down *any* of our roads and see good farming and good homes—Balanced Farming—on every hand.

ECONOMICS FOR THE FARMER

LAUREN SOTH

The Des Moines Register and Tribune

MOST of us who are members of this Association are engaged, one way or another, in trying to inform farmers about the economic factors affecting their businesses. It is surprising, therefore, how little time we devote to studying the best methods of doing this job. If we are to raise the general level of understanding of economic facts and principles, we cannot be satisfied merely with increasing the supply of information. We must also be concerned with our responsibilities of exposing the public to the information and of increasing its rate of absorption.

The reasons why it is important that we do a more effective job of transmitting economic information to farmers are self-evident: first, to help them adjust their individual business operations more rationally to a changing economic situation; and second, to help them make sounder judgments about governmental activities in agriculture.

I

When agricultural prices and land values flopped badly after the first World War, the demand for economic information grew enormously. The commercialization of the farming industry had long since reached a point where farmers were conscious of their relationship to the business cycle. There had been agitation for monetary inflation and other kinds of farm relief during the last half of the nineteenth century. But no previous price-cost squeeze had quite the impact on farm thinking of the 1920-21 affair. Farm people began to wonder about the factors which determined their prices. This was the period of heaviest assaults on the packing companies, the grain exchanges, the banks and other institutions which farmers believed were responsible for their difficulties. It led to the flurry of farm co-operative organization, to the McNary-Haugen episode and all sorts of plans for raising farm prices.

It also led to the first systematic effort to educate farmers about economic conditions which affected them. The Wallaces, Henry C. and Henry A., were prime movers in the effort to provide agriculture with more and better economic information. They began to publish charts of "hog profits and losses" in their farm paper, and later added similar diagrams on beef cattle and butter. Later

Henry A. Wallace added statistical information about general wholesale prices, industrial production, employment, carloadings, and other indices of business activity. He also began to publish his own forecasts of prices.

In 1923, Henry C. Wallace, as Secretary of Agriculture, called the first national farm outlook conference. The first outlook report covered only demand conditions and price prospects for wheat, cotton, tobacco, corn and hogs. Little effort was made to give it widespread circulation among farmers.

At the time this outlook work was getting started it was felt by many farm leaders that farmers would make the proper adjustments in crop acreages and livestock programs if they had the facts before them. They thought adequate economic information would prevent surpluses and help stabilize agricultural prices by making the market a more effective instrument for balancing supply and demand. There was even a "forward price" proposal advanced at this time to make the outlook work more meaningful and effective—and to reduce uncertainty in the farm business.

Of course a more perfect market was not the answer to the farm depression of the 'twenties. But because outlook work had been advocated as a panacea, it was discredited when farm conditions didn't get any better and then went from bad to very much worse in the Great Depression of the 'thirties.

Agricultural leaders turned their eyes toward federal government action to adjust production, along with purchases and loans to support prices of farm products. The theory behind these programs was that the free market couldn't be made to balance supply and demand. The idea, in contrast to that embodied in outlook work, was to substitute central direction and management for the automatic regulation of the market.

Although it may be true that the free market system is inadequate to direct the necessary adjustments in agricultural production and marketing in a time of violent economic change, it is fair to say, I think, that we have never done our utmost to try to make it work more efficiently. We haven't given the free market a really fair trial, for it is implicit that a smoothly functioning free market must have as its basis complete, accurate, understandable, and timely economic information to producers.

Neither our national government, our educational institutions, nor the press have been able to achieve anything like a satisfactory

dissemination of such information to farmers. Strangely enough, some of the groups and institutions which argue most vehemently for the free enterprise economy are least willing to spend money in a genuine effort to make it work in agriculture.

II

Paradoxically, the AAA programs have accomplished many times as much in acquainting farmers with economic information as the Extension Service has in all its 26 years of organized outlook programs. Whatever the AAA programs did or did not accomplish in the way of production control, they certainly did provide many farmers who never before had been reached by any educational agency with basic knowledge about the American economy and agriculture's place in it.

Each year in order to get compliance with its programs, the AAA brought to farmers in simple terms the supply and demand situation affecting the crop in question. The interpretation was slanted, of course, to induce farmers to go along with the adjustment. But still farmers were made aware of relationships and magnitudes—the impact of the foreign market, for instance, which they had not previously thought about. You who have worked with farmers during the last 20 years will bear me out on this.

This achievement in the field of economic education by the national farm adjustment programs is something which it seems to me deserves study. What are the reasons why AAA could interest farmers in the foreign market for wheat, when Extension couldn't? You cannot dismiss this question merely by saying AAA had the money, and farmers were interested in their pocketbooks. There is more to it than that.

One reason why AAA was more successful in economic education than the Extension Service was that it used local farmers to do the job. Local people know best what their neighbors are interested in and how to approach them with new information. Extension has always prided itself on its local leader system, and apparently this system has worked well in spreading information about farm production practices. But for some reason, the Extension people were never able to get this job done on *economic* information.

Why was the AAA able to get local leaders to do this job which Extension had been unable to do? Well, the committee-men were paid, for one thing, and Extension's local leaders were volunteers.

But aside from this, AAA had a definite sales argument to put over. It was shooting at a definite goal. The AAA workers were not troubled with doubts about the correctness of their program. They didn't try to bring out the "other side" of the question. Instead, they did their best to sway farmers to their way of thinking. Theirs was a dynamic, crusading movement, and it had a highly interested audience during those depression days. It attracted workers just because it was new and dynamic. Alongside it, the Extension outlook story was drab and dull.

Opinion researchers have found that no matter how skillfully an information campaign is waged, it will fail unless it is geared to the public's interests. All of us know from experience, also, that people learn more in discussion of "hot" or controversial issues than they do when they aren't emotionally worked up about them. We know from the mail which comes into our newspaper that controversy results in a much higher degree of knowledge. The recent outburst of Cardinal Spellman against Mrs. Eleanor Roosevelt unquestionably stimulated thousands of people to become better informed on the issue of public aid to schools, as well as upon the questions of religious freedom and separation of church and state.

The heated arguments over crop acreage control and other aspects of agricultural policy contributed to the wider spread of economic information through the AAA system—both among friends and enemies of the program.

When public interest is high, when controversy is alive, that seems to be the most favorable climate for getting across information. But there is one danger in trying to reach people on the basis of their interests alone. People nearly always seek information congenial with their prior attitudes. They select material to read which fits in with their own biases, and they go to meetings or listen to radio programs which strengthen their own convictions. Thus it is easy for educators, or others in charge of information campaigns, to be misled as to the number of people they are reaching and as to the amount of information they are getting across. The AAA has fallen for this to some extent, I believe. It has done a good job of educating the loyal followers of its programs, but it may not have reached out as far into the byways as it believes. The older AAA becomes the more it falls into the same rut as Extension or any other agency. It clings to its permanent "clientele" and to the methods and techniques it has used in the past.

There is supposed to be a high pitch of interest among farmers in agricultural price programs right now. The last election, according to the experts, was swung to the Democratic side primarily because Midwest farmers didn't like the Republican performance on farm legislation. The Democrats held a big shindig in Des Moines to sell the Brannan Plan and capitalize on this feeling among farmers.

Yet a Gallup poll just over two weeks ago showed anything but a burning interest among farmers in price support programs. A sample of Midwest farmers were asked whether they had been following the discussion of the Brannan Plan and what their opinions of it were. Less than half of them, 43 percent, said they had been following the discussion. Fifty-seven percent had little idea of what the plan was all about.

This should not be so surprising to us when we realize how slow the spread of even simple production information is among farmers. A large number of Iowa farmers still don't feed balanced rations to livestock. It took many years for Iowa farmers to adopt hybrid seed corn, even after it had been proved. We should not expect farmers to follow and grasp complicated economic ideas like the Brannan Plan within a few months. Yet many of our information programs are handled as though *every* farmer were deeply interested, able to start at the same point, and equipped with all the background that the best informed farmers have.

III

The National Opinion Research Center concluded, in the study referred to earlier, that there exists in our population a hard core of chronic "know nothings." Surveys consistently find a certain proportion of the public which is not familiar with any particular event or idea. This group of "know nothings" is the group which we do not reach with the newspapers, the radio, in meetings, or any other way. There is something about these uninformed people which makes them harder to reach, no matter what the level or nature of the information.

Considering the amount of space which the newspapers give to the national debt, the federal budget and related information, I was shocked recently to see a Gallup Poll report which indicated that nearly two-thirds of the people surveyed (64 percent) would make no estimate of the federal budget for the last year. Only six percent were able to place the budget correctly within a range of 35 to 45 billion dollars. Another 30 percent guessed the budget out-

side this very wide range. About the same percentages of ignorance were shown on information about the national debt. Only seven percent of the people were able to place the debt in the range of 225 to 275 billion dollars.

Lack of knowledge of the figures does not mean, of course, that many of these people do not have some concept of the issues in fiscal policy, but it surely is an indication that this kind of information is not widespread.

The size of this bloc of "know nothings," added to the still larger bloc of those who know *little* about economic information is something that newspapermen, educators, and politicians need to give more attention to. The farmers who have inadequate economic information still make decisions about production and marketing on the bases of prejudice, hunch, and guesswork. They make political decisions on the same inadequate grounds—decisions about farm programs, about international trade policy, and about industrial and labor policy.

The problem is both a matter of making democracy work better and of making the free market system in agriculture work better.

IV

Unfortunately, we know very little about how to go ahead with this challenging assignment. We need first of all research on how farmers get information about markets, prices, general business conditions, and so on. Then we need research on how they use this information to form their judgments.

In the absence of better and more scientific groundwork, it seems to me that state college Extension Services and other agencies dealing with farmers could learn something from the experience of the last 15 years.

For one thing, it appears to me that the Extension Services will never do an adequate job of economic education until they become bold enough to deal with controversial issues. I am not advocating that they try to promote a particular point of view, as institutions, in the manner of the AAA. But I do think they ought to give individual staff economists complete freedom to express their views as they see fit on questions of economic policy—insisting only that the *basis* for these views be accurate and unprejudiced facts. Too many of our economic research and Extension programs are circumscribed by the political forces in the states, working through the college administrations. I have seen a good many economic

education programs bog down because they were so insipid. They lacked drive and carry-through because staff members did not feel free to take a position and argue it if it happened to be unpopular with politically-powerful groups. I believe more could be accomplished in economic education among farmers if more economists were free to stand up and be counted on the hot issues.

I have used the AAA as an illustration of this more vigorous and more effective educational approach. I could also cite some of the work done by some labor unions during recent years, and increasingly by farm organizations.

College administrators spend too much time worrying about the effect of their educational programs in the social sciences. They credit discussion leaders who express their own opinions with more influence than they actually have.

Remember, I am talking about *ways and means* of making more farmers acquainted with factual information about economic conditions and issues of the day—not about persuading them to a certain point of view. Strongly opinionated presentation of economic information does not necessarily change the attitudes of the audience. There is ample evidence to show that while some attitudes change, though usually very slowly, information of this kind does not affect attitudes of different people equally, and many not at all.

For example, the AAA fell a long way short of convincing all farmers of the correctness of its approach to agricultural adjustment. The Democrats may gloat about the last election “proving” farmers don’t like flexible price support and want rigid crop controls, but they should not forget the previous two elections when the Midwest farm vote was Republican. One could make just as good a case that farmers were *opposed* to crop acreage restrictions.

The point is that the AAA’s slanted and opinionated presentation of economic information nevertheless got the facts across to many more farmers than a more objective, and duller, method would have.

The CIO does not convince all its members on its numerous policy positions, but its vigorous manner of presentation does increase the absorption rate of a great many facts about prices, wages, industrial production, and other economic indicators. I would recommend to Extension economists, editors, and administrators that they look over some of the publications of both the CIO and AFL for examples of effective economic education. What

these educators should be worried about is not the great effect of their opinions but the *lack of effect* of their dissemination techniques.

This same principle of taking sides and being *for* or *against* something can be applied to outlook information. Many writers of outlook reports are scared to death that they might be wrong in a forecast. I wouldn't be so worried about being wrong as about not being listened to. If an economist who spends all his time studying the economic situation is afraid to form a judgment, how does he expect his readers to form one, or to pay attention to him? In this connection, let me point to the Doane Agricultural Service as an example of effective outlook information. It is not satisfied to present the facts alone. It gives the facts color and meaning by going the next step and forming a judgment. It probably gets across a good deal more outlook information to farmers than many of our state colleges do.

It isn't necessary to go out looking for a fight in order to bring economic information to farmers. But avoiding controversy can be a way of *not* accomplishing much in this field.

While it is important that educational institutions, as institutions, remain objective, this does not mean individual staff members must never commit themselves.

In fairness to the agricultural colleges, we should recognize that it is not easy for them to conduct economic information work about hot political issues. With loyalty investigations rampant in both state and national governments, it takes some courage to try to do an educational job in social science. It is much easier to just pass by anything that looks like it might create trouble. Still, shying away from these issues by the educational agencies, who are best equipped to discuss them and bring out the relevant facts and information, leaves the field to the charlatans and interest groups.

Getting economic information to farmers is at least as important as any other agricultural program being carried on today. It deserves a great deal more study and imagination on the part of educational institutions, government agencies, and the press.

DISCUSSION

GEORGE A. POND
University of Minnesota

Mr. Morse and Mr. Soth are inclined to accuse farm economists in general and extension economists in particular with being unduly cautious

and conservative in their interpretation of the economic outlook to farmers. It might be an interesting study for some enterprising and imaginative graduate student to analyze the "batting averages" of farm economic prognosticators and their appraisal by farmers.

Director Burch develops one point that the other two speakers fail to mention—namely the importance of having the farmer understand the reasoning behind any economic program or planning to which he is a party.

One can hardly believe that either Mr. Morse or Mr. Soth thinks the farmer will be satisfied or most effectively served by the "dope sheet" type of economic outlook, although that could easily be inferred from their papers. I agree with them that farmers would like to have a definite specific statement of the economist's opinion on prospective prices.

Even if the economist has the right advice for the occasion it may have no bearing on the next economic problem that confronts the farm operator. If he has been taught the process of solution, he can apply it to the new problem and get the answer that does fit.

We should be indebted to Mr. Morse for his emphasis on the increasing proportion of farm inputs that involve cash outlay. This is significant from the standpoint of the vulnerability of farmers in depression periods. However there is still a large proportion of fixed costs in farming that cannot be escaped by curtailing production. I question whether any large number of farmers will cease or severely curtail operation voluntarily in the next depression.

The heavy stress Mr. Morse lays on the part government programs play in determining the price outlook for farmers rather negates the emphasis he places on accurate and specific economic forecasts.

Mr. Soth's major emphasis, as one might logically expect of a journalist, is on publicity methods. His comparison of extension methods in the education field with the sales efforts of AAA workers seems hardly an altogether valid one. I also question the significance of his comparisons between the educational methods of economic extension workers and the success of union labor leaders in rallying workers to their program. Here again monetary rewards and various types of coercion make this distinctly a "horse of a different color." To develop successful pressure groups which sponsor programs that may be distinctly uneconomic or to sell them on the basis of misinformation, even if distinctly successful is hardly comparable with extension teaching.

I am sure Mr. Soth does not mean what he seems to imply in lauding the "spell-binder" and the "rabble rouser" because they are able to influence people to action regardless of whether that action is good, bad, or indifferent. Extension and research economists may at times be colorless and prosaic but that is no reason for them to court popular acclaim by pressing a cause just because it can be made to appeal to certain special interest groups. It is better to sell a little sound economics than, by much sound and fury to stimulate a lot of phony thinking.

DISCUSSION

A. SHULTIS

Extension Service, California

Mr. Morse in his closing paragraph states that able farm managers realize that economists cannot always be right in their forecasts but that their best judgment is wanted. This would imply the willingness and ability of the able farm manager to consider the evidence and draw his own conclusions as to the most profitable farming plan for a particular farm. But there are many people managing farms that are not able and might need help. Mr. Morse tells them through the Doane-Agricultural Digest and according to Mr. Soth more effectively than do we in the Extension Service. We should take some lessons. Certainly farmers need more specific and timely information for planning their operations and their buying and selling. Public agencies such as the U.S.D.A. and Federal-State Crop and Livestock Reporting Services and Market News services are doing a bigger and better job all the time. But more and better distribution should be possible even with existing knowledge, funds and personnel.

Mr. Soth makes a case that merely increasing the supply of this economic information won't get it in the hands of farmers. We need to time it as to interest, put it in understandable, useful form and then use all available methods and channels to get it in the hands of farmers in such a way that they will act on it. He feels we must not avoid controversial issues or taking sides. We gain a hearing only on something of intense interest and even then only with an argument and not a dispassionate exposition of both sides.

Managing a farm for highest total profit or smallest loss over the next few years of uncertain prices, production allotments, continuing high costs and additional new scientific and mechanical developments will require high professional competence in the art of farm management. There are many able farm managers but there are far more that need some training and help. Here is a big job with plenty of room for all agencies—public and private.

There is still plenty of room for private professional assistance to many farmers able and willing to pay for service beyond that which can be obtained free. The Doane Agricultural Service of which Mr. Morse is president, is certainly making a large and important contribution to better farming along with many similar agencies and private consultants. It is surprising there is not more of such service available in the far west.

Perhaps one of the most promising methods of applying the art of farm management to the average family farm is through the Balanced Farming Associations in Missouri and the Farm Management Associations in some of the other middlewestern states. The essence of these plans is the payment by the farmer of part of the cost of a farm planning service beyond that obtainable in free educational programs.

The farm family paying part of the cost of assistance was cited by Director Burch as favoring the full development and use of the farm and home plan. Apparently this cost has not been a deterrent to the growth of the Balanced Farming Associations. Lack of trained personnel has been the main deterrent.

Director Burch raises a significant question about tying in the Agricultural Conservation Program with Balanced Farming Plans. We have doubtless heard the suggestion that A.C.P. payments be made only where there is a sound land use plan. Our first reaction is to shudder at a shotgun wedding of such payments to the art of farm management. Farm plans poorly prepared to qualify for an A.C.P. payment might discredit the whole idea of farm planning. On the other hand A.C.P. practice payment to share the cost of a developed farm plan might be merited. Here is a real opportunity as Director Burch says for a great voluntary program to obtain and pay for soil conservation and obtain crop adjustment through mass farm planning. It will need some help from the farm management field.

As a representative of the far west, I should present an alibi regarding our small progress in individual farm planning. It looks good, but we can't seem to make much headway. In California our commercial farms are fairly large and highly specialized with a rather narrow range of adapted and profitable enterprises. But we see many shifts and readjustments coming which will require intelligent reorganization of many individual farm businesses. We must improve our abilities, material and methods in farm planning.

These three papers all present a convincing case for a larger number of workers better trained in the art of farm management.

INTEGRATING ECONOMIC AND LEGAL THOUGHT ON AGRICULTURAL COOPERATIVES

A. LADRU JENSEN

University of Utah

la
v
THE shift to more government in economic life arises primarily because law in a democracy is not merely a system of authoritative legal materials; it is also a specialized form of social control resulting from organized pressure of economic and political groups in the social order. Probably no better example of political pressure for better bargaining power can be found anywhere than the pressure of American laborers and farmers to gain the legal right to organize for group welfare.

Time permits only a limited consideration of details. What I shall chiefly endeavor to present to you is an outline of the persistent, powerful, and slow moving group forces in their economic and legal aspects, from which is now emerging the modern cooperative corporate associations of farmers in this country.

Common Law and Free Competition

History is replete with the struggles of men to find freedom and economic justice within the legal framework of different social orders.¹ Out from the volumes comes one clear lesson: that while a country is not populated appreciably beyond its optimum relation between numbers and consumable resources, a capitalistic-democratic form of government has insured the largest number the surest political freedom, the strongest financial incentive, the widest economic opportunity, and the greatest individual power to command goods and services.

On the other hand, the very freedoms inherent in a dynamic modern capitalistic democracy have also produced the most and largest private-profit corporations with the greatest concentration of economic power.

As Pericles emphasized, it is a biological rule of life that big fishes live on little fishes. Similarly the freedoms which allowed big corporations to be controlled by a few citizens provided, and to a con-

¹ Toynbee, Arnold Joseph, *The Study of History, Abridgment of Vols. I-VI* by D. C. Summerville, Oxford University Press, 1946.

siderable degree still provide, an easy method for the exploitation of unorganized farmer and consumer groups.²

The legal controls which the common law exercised at about the beginning of the nineteenth century to insure a free and fair exchange of goods and services were relatively simple and usually effective. Both criminal and civil law made illegal all combinations in restraint of trade, except, that partnerships, joint stock associations and a few monopolistic Royal Charter corporations were allowed.³

The laissez-faire economy, following the time of Adam Smith (1723-1790) and David Ricardo (1772-1823), was grounded on the legal principle that the function of government was to preserve free competition between individuals and small unincorporated associations. Except as the law allowed partnerships, joint stock associations and licensed monopolies, it was the duty of the State to destroy every attempt to profit by combinations restraining trade or enhancing prices in any degree.⁴ It was generally believed that if free competition could thus be preserved, business efficiency and

² Nourse, Edwin G., *From Dogma to Science in Cooperative Thinking*, American Cooperation, American Institute of Cooperation, Washington, D. C., 1946, pp. 10-11.

See also: Berle Jr., Adolf A., and Means, Gardner C., *The Modern Corporation and Private Property* The Macmillan Co., N. Y. 1933

The classical statement on exploitation of farmers by parties more strategically situated was quoted by the United States Supreme Court in the case of *Liberty Warehouse Co. v. Burley Tobacco Growers Co-operative Marketing Ass'n* (276 U.S. 71, 1928) from the Kentucky Supreme Court as follows:

"We take judicial knowledge of the history of the country and of current events and from that source we know that conditions at the time of the enactment of the Bingham Act were such that the agricultural producer was at the mercy of speculators and others who fixed the price of the selling producer and the purchasing price of the final consumer through combinations and other arrangements, whether valid or invalid, and that by reason thereof the former obtained a grossly inadequate price for his products. So much so was that the case that the intermediate handler between the producer and the final consumer injuriously operated upon both classes and fattened and flourished at their expense. It was and is also a well known fact that without the agricultural producer society could not exist and the oppression brought about in the manner indicated was driving him from his farm, thereby creating a condition fully justifying an exception in his case from any provision of the common law, and likewise justifying legislative action in the exercise of its police power." (208 Ky. 649, 271 S.W. 695.)

³ See: Oppenheim, S. Chesterfield, *Cases on Trade Regulation*, West Pub. Co., 1936, p. 8 For a brief history of Royal Charter corporations which were chartered monopolies in foreign trading, such as the Hudson Bay Fur Company and East India Company, see: Williston, Samuel, *History of the Law of Private Corporations Before 1800*, 2 Har. L. Rev. 109.

⁴ Oppenheim *supra* note 3 quotes from Blackstone and Coke: "In England the original and narrow meaning of 'monopoly' was 'a license or privilege allowed by the King for the sole buying and selling, making, working or using of anything whatsoever, whereby the subject in general is restrained from the liberty of manufacturing or trading which he had before.' Also associated with the problem of monopoly were the early common law offenses of engrossing, forestalling and regrating."

fair prices would result and thus the general welfare would be insured. The economic results in a large measure justified the belief in competitive individualism as an efficient regulator of industrial and commercial life.

Thus, if two or more partnerships, joint stock associations, laborers or farmers contracted or combined to gain a financial advantage in the market they were guilty of an illegal conspiracy in restraint of trade and could be prosecuted criminally⁵ at the option of the State or enjoined in a civil action in a court of equity at the option of an interested citizen.⁶

As late as 1913, the Supreme Court of Iowa invoked the common law doctrine of illegal conspiracy against the Decorah Farmers Cooperative Society because a local group of farmers had voluntarily associated together to jointly demand a slightly higher and fairer price than Mr. Reeves, the Chicago buyer, was willing to pay for their hogs.

The court did not analyze whether its own duty was to equalize as far as possible the bargaining power of the farmers against that of the big packing company of Chicago whom Mr. Reeves represented. It enforced the traditional, but now economically outmoded, common-law doctrine that free competition between individual sellers and buyers must be upheld, even if the latter possessed the advantage of quasi-monopolistic bargaining power.

A permanent injunction was decreed against the enterprising Decorah hog raisers. The court thus dissolved the cooperative society and relegated the farmers once again to the disadvantageous position of competitive individual selling of their livestock at wholesale prices, while at the same time they were compelled to pay retail prices for the things they purchased.

It is pleasing to note that this bad decision is one of the last in this country to deny to farmers the right to organize a cooperative through which to jointly market their products.

Industrial and Legal Inventions Concur

Limits of time preclude even a highlight tracing of the concurrent growth of industrial inventions and assembly line techniques on

⁵ *Rex v. Bykerdike*, Lancaster Assizes, 1832, 1 Moo. & R. 179; *People v. Fisher* 14 Wendell 9, N.Y. (1835). In the latter case the New York court reaffirmed the principle that it was a criminal conspiracy to combine and strike for a raise in wages; and *State v. Donaldson* 32 N.J. Law 151, 90 Am. Dec. 649 (1867).

the one hand, and of their legal counterparts: parent and subsidiary corporations,⁷ holding companies,⁸ voting trusts,⁹ affiliated corporations by use of interlocking directorates and non-par stock.¹⁰

Suffice to say that all anti-trust attempts to restrict the growth of big corporations and corporate combinations, met with little success except in the relatively limited field of Public Utility Regulation.¹¹ Here by the use of rate making powers a fair profit was usually defined as, and enforced at, approximately six percent on invested capital.

During the last half of the nineteenth century private-profit corporations of all kinds grew and flourished—through stock acquisitions, consolidations and mergers. Their perpetual life, limited liability for members, centralized management and capacity to command the best professional skills, all made for rapid and extensive accumulations of capital, and of surplus profits. For a time their indirect benefits of efficient production appeared to outweigh the evils of their great quasi-monopolistic power. About 1880 many courts, and the business and financial interests generally began to praise big corporations more than they condemned them.¹² Mechanization and corporate efficiency did supply an increasing flow of goods and services, usually at reduced prices.

By 1890, however, labor and agriculture generally realized that their bargaining ability to extract their just economic due from the total annual goods and services was feeble when compared with the bargaining power of capitalistic corporate groups inherent in the pricing power of big corporations.

Nevertheless Congress was not yet ready to increase the bargaining power of labor and agriculturists by allowing them to combine for group welfare. Congress resolved upon one last vigor-

¹¹ Public Utility regulation by the states gained impetus by the enactment of the Interstate Commerce Commission Act of 1887, 43 Stat. 801, 49 U.S.C.A. Sec. 1 et. seq.

¹² Justice Field in writing the decision of the Court in the Railroad Tax case of *San Mateo County v. Southern Pacific Railroad* (Cir. Ct. D. Calif.) 13 Fed. 722, 743 (13 Fed. 722, 743 (1882)) sang the praises of the corporations, as follows: "As a matter of fact, nearly all enterprises in this state, requiring for their execution an expenditure of large capital, are undertaken by corporations."

ous effort to curb big profit-corporations and to try to make them compete with each other in the public interest. This economic judgment and objective was implemented by the enactment of the Sherman Anti-Trust Act of 1890.¹³

There were, however, courageous legal-economic scholars on supreme courts in many places who thought the Sherman Anti-Trust Act was inadequate. They saw more clearly the difficulties of curbing the growth or activities of business corporations. They declared a new duty for both legislatures and courts: namely, to help equalize bargaining power of competing economic classes by making and enforcing laws to strengthen labor and agriculturists against the enhanced economic power of big business corporations.

For a few decades these thinkers were the dissenters, but slowly their economic views gained wider acceptance.

Justice Oliver Wendell Holmes was the greatest dissenter of them all. With broad vision, wise understanding and resolute courage he led the vanguard of a newly forming economic-legal thought. In the *Vegeahn* labor case of 1896,¹⁴ in which the majority of the court denied a right of peaceful picketing, Justice Holmes wrote one of his most classical dissents, as follows:

It is plain from the slightest consideration of practical affairs, or the most superficial reading of industrial history, that free competition means combination, and that the organization of the world now going on so fast means an ever increasing might and scope of combination. It seems to me futile to set our faces against this tendency. Whether beneficial on the whole, as I think it, or detrimental, it is inevitable, unless the fundamental axioms of society, and even the fundamental conditions of life, are to be changed.

One of the eternal conflicts out of which life is made up is, that between the effort of every man to get the most he can for his services, and that of society, disguised under the name of capital, to get his services for the least possible return. Combination on the one side is patent and powerful. Combination on the other hand is the necessary and desirable counterpart, if the battle is to be carried on in a fair and equal way.

The economic argument of Justice Holmes was just as applicable to a right for farmers to combine to get a fair price for their products as it was for labor to combine to get a fair wage for its services.

Following the enactment of the Sherman Act in 1890 many states passed anti-trust laws. Some even placed anti-trust provisions in

¹³ 26 Stat. 209 (1890), 15 U.S.C.A. Sec. 1 et seq. (1940).

¹⁴ *Vegeahn v. Gunter* 187 Mass. 92, 44 N.E. 1077 (1896).

The principle of this dissent was upheld in 1921 by the United States Supreme Court, Chief Justice Taft writing the decision in the case of *American Steel Foundries v. Tri-City Central Trades Council* 257 U.S. 184, (1921).

their amended constitutions in an endeavor to check the concentration of capital and the growth of corporate powers.

Illinois passed an anti-trust statute in 1893 which declared criminal and void any combination of two or more persons, firms, corporations, or association of persons, to restrict trade, to affect the price of a commodity, or to prevent competition on an individual basis in the manufacture, transportation, sale or purchase of merchandise, products or commodities, except "that this act shall not apply to agricultural products or livestock while in the hands of the producer or raiser."¹⁵

In 1902 the Supreme Court of the United States held the Illinois antitrust statute unconstitutional and void in the *Connelly Case*¹⁶ on the ground that it favored farmers and thus violated the equal protection clause of the 14th Amendment. The court, with only Mr. Justice McKenna dissenting, said that the separate classification of agriculturists was arbitrary and capricious, since all persons mentioned in the statute fell within the same general class: persons engaged in domestic trade.

The dissent of Mr. Justice McKenna upheld the Illinois legal classification as fully warranted by the difference between farmers and city merchant men.¹⁷ His discerning dissent, as we shall see, became the opinion of the Supreme Court in 1940 in *Tignor v. Texas*.¹⁸

Reasonable Enhancement of Price Allowed After 1911

The Supreme Court of the United States diligently endeavored for about fifteen years to enforce the Sherman Anti-Trust Act in the spirit in which Congress wrote it, namely, that "every contract, combination in the form of trust or otherwise, or conspiracy, in

¹⁵ See: *Connolly v. Union Sewer Pipe Company* 184 U.S. 540, 554 (1902).

¹⁶ *Ibid.* The 14th amendment declares in part that "No state shall deny to any person within its jurisdiction the equal protection of the laws."

¹⁷ Mr. Justice McKenna aptly observed in his dissent in the *Connolly Case* as follows: "The excluded class is composed of farmers and stock raisers while holding the product or livestock produced by them. The included class is composed of merchants, traders, manufacturers, all engaged in commercial transactions. That is, one class is composed by persons who are scattered on farms; the other class is composed of persons congregated in cities and towns, not only of natural persons but of corporate organizations. In the difference of these situations, and in other differences which might occur to any reflection, might not the legislature see differences in the opportunities and powers between the classes in regard to the prohibited acts?"

¹⁸ *Tignor v. Texas*, 310 U.S. 141 (1940).

restraint of trade or commerce among the several states"¹⁹ was a misdemeanor and also illegal by civil law. This codification of the common law against monopoly and engrossing²⁰ was for the chief purpose of preventing an "enhancement of price" by reason of contract or combination of the corporation concerned.

By 1911, however, almost the entire membership of the Supreme Court decided that the common law doctrine that all restraints of trade were illegal just could not be legally enforced in a corporately organized economy. The court's only alternative was to make a new legal doctrine compatible with the admitted existence of expanding corporate combinations. The new doctrine allowed the courts to try to curb selfish corporate actions for excessive economic gains of the control group and the investors, while it required the court to determine that some corporate combinations did not enhance, or attempt to enhance, price unduly. The United States courts must now distinguish between good and bad corporate combinations. This inevitable decision was fraught with unknown risks and hazards for it was a venture into uncharted legal-economic seas.

In 1911 the United States Supreme Court announced "the rule of reason" in the *Standard Oil Company*²¹ and the *American Tobacco Company*²² cases with only Justice Harlan dissenting. Henceforth not all combinations restraining trade would be held illegal but only those which unduly or unreasonably enhanced or attempted to enhance the price of commodities or products. We shall trace this idea into the spirit and language of the Capper-Volstead Act²³ passed eleven years after these decisions.

¹⁹ See note 13. In *Northern Securities Co v United States* 198 U.S. 197 (1904) the Court observed: "A partnership is not a contract or combination in restraint of trade between the partners unless the well known words are to be given a new meaning invented for the purpose of the Act."

²⁰ *Standard Oil Company v United States* 221 U.S. 1, 4, (1911).

²¹ *Ibid.* The court, Mr. Chief Justice White writing the opinion in the *Standard Oil Company* case said,

"To treat as condemned by the Act all agreements under which, as a result, the cost of conducting an interstate commercial business may be increased would enlarge the application of the act far beyond the fair meaning of the language used. There must be some direct and immediate effect upon interstate commerce in order to come within the act"

If the criterion by which it is to be determined in all cases whether every contract, combination, etc., is a restraint upon trade within the intendment of the law, is the direct or indirect effects of the acts involved, then of course the *rule of reason* must be the guide."

²² *United States v. American Tobacco Company* 221 U.S. 106 (1911)

²³ 42 Stat. 888 (1922), 7 U.S.C.A. Secs. 291-292 (1940).

Section 6 of the Clayton Act

The establishment of the rule of reason had opened Pandora's Box of political pressures for economic group advantage. Within three years after the Supreme Court announced the "rule of reason" the classical dissent of Justice Holmes in the *Vegeahn* case, *supra*, became Congressional policy with the enactment of Section 6 of the Clayton Act²⁴ of 1914, both as to labor and farmers. The right of these economic classes to organize for mutual self help was for the first time recognized by Congress. Thus in 1914, it became legal for laborers and farmers to impose at least reasonable organizational restraints upon interstate commerce for the purposes, respectively of securing higher wages, and higher prices for agricultural commodities and increasing their bargaining power in a predominantly corporate economy.

Section 6 of the Clayton Act was construed favorably by the Federal District Court for Oregon in *United States v. Dairy Cooperative Association*²⁵ in 1943. In quashing the indictment for alleged criminal conspiracy to enhance the price of milk Judge McCollough wrote:

I am told this is the first case brought by the Anti-Trust Division of the Department of Justice against a farmer's cooperative acting alone and not in concert with others. . . . I am asked to scuttle the plain language of the Clayton Act as to cooperatives, as the anti-labor courts scuttled the labor provisions of the same act. When Congress said that cooperatives were not to be punished even if they became monopolistic it would be ill-considered for me to hold to the contrary.

The Capper-Volstead Act of 1922

While the Clayton Act, *supra*, authorized the organization of non-profit, *non-stock* cooperative corporations, the right of agriculturists to organize cooperative corporations was given much broader sanction by the enactment of the Capper-Volstead Act²⁶ in 1922.

²⁴ 38 Stat. 730 (1914), as amended 15 U.S.C.A. Secs. 12-27. Section 6 of the Clayton Act reads: "The labor of a human being is not a commodity or article of commerce. Nothing contained in the antitrust laws shall be construed to forbid the existence and operation of labor, agricultural or horticultural organizations, instituted for the purpose of mutual help, and not having capital stock or conducted for profit, or to forbid or restrain individual members of such organizations from lawfully carrying out the legitimate objects thereof; nor shall such organization or the members thereof, be held or construed to be illegal combinations or conspiracies in restraint of trade under the anti-trust Laws."

²⁵ *United States v. Dairy Cooperative Association*, 49 Fed. Supp. 475 (D. Ore. (1943)).

²⁶ 42 Stat. 888 (1922), 7 U.S.C.A. Secs. 291-292 (1940).

By this Act Congress granted the legal right to agriculturists to organize stock as well as non-stock cooperative corporations. So long as the organization and operation of an agricultural cooperative marketing corporation did not "unduly enhance the price" of the products marketed, it was exempt from the provisions of the Sherman Anti-Trust Act.

The Capper-Volstead Act also inaugurated the principle of the determination of a fair price for agricultural commodities which expanded enormously under the Office of Price Administration during the second World War, for it gave the Secretary of Agriculture the right and duty of determining when the price of an agricultural product had been "unduly enhanced," that is, enhanced above a fair price, by reason of cooperative corporate organization or operation, or both. This difficult economic task has not often been exercised by the Secretary of Agriculture.

The Capper-Volstead Act also contains the beginnings of a legislative definition of a true cooperative.

In order for a cooperative to gain limited anti-trust immunity under the Sherman Anti-Trust Act, interpreted by the "rule of reason," four requirements are set out. The requirements for qualification as a Capper-Volstead cooperative are:

First, The cooperative corporation must be organized only by agriculturists.

Second, Each association must be operated for the mutual benefit of the members thereof as producers except as to parent subsidiary cooperatives which are allowed under the Act.

Third, The association shall not deal in the products of non-members to an amount greater in value than those handled by it for members.

Fourth, The association must conform to one or both of the following:

- a. One member, one vote, irrespective of capital owned, or
- b. Dividends on stock or membership capital shall not exceed eight percent.²⁷

The Capper-Volstead Act is truly the Magna Charta of cooperative agriculture.²⁸

Three of the above incidents of an agricultural cooperative are found in the rules of the early Rochdale Equitable Purchasing Cooperative of England where in about 1844, twenty-eight friends and fellow craftsmen formed a new type of unincorporated, non-profit, joint stock association to purchase necessities at a saving

²⁷ Note 23.

²⁸ See Jensen, A. Ladru, *The Bill of Rights of U.S. Cooperative Agriculture*, 20 *Rocky Mountain Law Review*, 181-189 (Feb. 1948).

over what they were required to pay in the ordinary retail market.

Mr. Edwin G. Nourse states the essence of the Rochdale dogma thus:

If you require every member to buy a share of capital stock and limit the amount any one member may hold, if you give each member only one vote, if you put a low ceiling on interest paid to purchasers, follow market prices, sell for cash, and return any residue in proportion to patronage, you have a cooperative.²⁹

We shall examine further statements as to the essentials of a cooperative after first observing how the Capper-Volstead Act has fared in the United States Supreme Court.

Six years after its enactment the Act received favorable recognition by the Supreme Court in the case of *Liberty Warehouse Co. v. Burley Tobacco Growers' Co-op. Marketing Association*.³⁰ In a unanimous decision the court said:

It is stated without contradiction that cooperative marketing statutes substantially like the one under review (Ky. Bingham Act, 1922) have been enacted by forty-two states. Congress has recognized the utility of cooperative associations among farmers in the Clayton Act, 38 Stat. 730; the Capper-Volstead Act, 42 Stat. 388; and the Cooperative Marketing Act of 1926, 44 Sts. 802. These statutes reveal widespread legislative approval of the plan for protecting scattered producers and advancing the public interest. Although frequently challenged, we do not find that any court has condemned a single feature of the plan with the single exception of the Supreme Court of Minnesota.³¹

Although the *Liberty Warehouse* case indicated that agricultural cooperatives were held in high favor by the court, nevertheless the case did not overrule the *Connelly Case*, *supra*, which held invalid the exemption of cooperatives from the Illinois Anti-Trust Law, but side-stepped it. The Warehouse Company, with all other persons was forbidden to induce a member of the cooperative to refuse to

²⁹ Nourse, Edwin G., *From Dogma to Science in Cooperative Thinking*, American Cooperation, American Institute of Cooperation, Washington, D.C. (1946) p. 9.

³⁰ *Liberty Warehouse Co. v. Burley Tobacco Growers' Cooperative Marketing Association*, 276 U.S. 71 (1928).

³¹ *Ibid.* In addition to the statutes above cited a partial list of federal statutes supporting cooperatives are: The War Finance Corporation Act of 1918; The Packers and Stockyards Act of 1921, 42 Stat. 159, 7 U.S.C.A. 181; The Grain Futures Act of 1922, 12 Stat. 993, see *Board of Trade v. Olsen*, 262 U.S. 1, Federal Intermediate Credit Bank Act of 1923, 42 Stat. 1454, 12 U.S.C.A. 1021; Agricultural Marketing Act of 1929, 46 Stat. 11, 12 U.S.C.A. 1141; Farm Credit Act of 1933 authorizing the banks for cooperatives, 48 Stat. 257, 12 U.S.C.A. 1184, Robinson Patman Act of 1936, 49 Stat. 1526, 15 U.S.C.A. 13, The Rural Electrification Act of 1936, 49 Stat. 1363, 7 U.S.C.A. 901 and the Commodities Exchange Act of 1936, 49 Stat. 1491, 7 U.S.C.A. 451.

perform his marketing contract upon a statutory penalty of \$500 for so doing. The court said, "There is no basis on which to invoke the equal protection clause on which the Connelly Case was decided." So the question was left open for a later decision.

In 1940 Justice Frankfurter wrote the opinion of the Supreme Court in the case of *Texas v. Tignor*.³¹ The Texas Anti-Trust statute had general application except that it did not apply "to agricultural products or livestock in the hands of the producer or raiser." The Court overruled the old Connelly case, *supra*, of 1902 and held that the Texas statute was not violative of the equal protection clause of the 14th Amendment but was reasonable classification.

The Court in adopting the reasoning of the dissent of Justice McKenna in the Connelly Case, *supra*, said:

Since Connelly's Case was decided nearly forty years ago, an impressive legislative movement bears witness to general acceptance of the view that the difference between agriculture and industry calls for differentiation in the formulation of public policy. The states as well as the United States have sanctioned cooperative action by farmers; have restricted their amenability to anti-trust laws, have relaxed their organizations from taxation.

Congress and the states have sometimes thought it necessary to control the supply and price of agricultural commodities within their respective spheres of jurisdiction and the constitutional validity of these measures has been sustained. . . .³²

These various measures are manifestations of the fact that in our national economy agriculture expresses functions and forces different from the other elements in the total economic process. . . . The Fourteenth Amendment . . . does not require things which are different in fact or opinion to be treated in law as though they were the same. And so we conclude that to write into law the differences between agriculture and other economic pursuits was within the power of the Texas legislature.

The legal right of agriculturists to organize large parent-subsidiary, federated cooperative corporations to help enhance the price of their products to a fair price³³ is now firmly established. This does not mean however that agricultural cooperative corporations may contract or combine with other persons, natural or corporate, to enhance the price of agricultural products marketed by the cooperative even if the price by so doing would not be unduly enhanced.

³² Note 18.

³³ *Ibid.*, see: *Milford v. Smith* 307 U.S. 38, 83 L ed 1092, 59 S Ct 648; *United States v. Rock Royal Cooperative*, 307 U.S. 533, 83 L ed 1446, 59 S Ct 993; *Nebbia v. New York* 291 U.S. 502, 78 L ed 940, 54 S Ct 505, 89 ALR 1469.

The contract or combination with a third party to stabilize, enhance or affect prices, was held to be violative of the Sherman Anti-Trust Act in *United States v. Borden Company*.³⁴

The Court held that when the Pure Milk Association, a lawful cooperative under the Capper-Volstead Act, combined with a drivers' union, a Chicago milk distributor, and the Chicago Municipal authorities to control the Chicago milk market, such attempt irregardless of whether the present price was fair or not was an illegal conspiracy under the Sherman Anti-Trust Act, and the Capper-Volstead Act was no protection to the Pure Milk Cooperative Association which had become one of the parties to the illegal combination.

Bargaining Power and Income Tax Exemption

By a provision in the Federal Income Tax Act of 1926³⁵ continued to the present time, agricultural cooperative associations whether incorporated or not may qualify for so-called tax exempt status if they meet eight specific legal requirements which we shall examine shortly.

The phrase "so-called tax exemption" is used to call attention to the confusion existing in the minds of many people who erroneously believe that patronage refunds, paid to members by reason of a contract obligation to do so existing prior to the receipt of income, are deductible from cooperative income in determining Federal income tax, if any. The cooperatives are not exempt from taxes on these funds. Patronage refunds are not deductible, but are excludable from the gross income of the cooperative agent and includable in the gross income of the principal, patron member. The only income that is legally exempt in a true cooperative is amounts used to pay dividends on capital and possibly some limited reserves in some cases.³⁶ Whether a cooperative gains exemption on amounts paid out as dividends and in some cases on some accumulated reserves, or operates as an agent at cost and avoids accumulation of taxable income by remitting, under prior contract obligation, all profits to its patrons as principals—in

³⁴ *United States v. Borden Company* 308 U.S. 188 (1939) reversing 28 F. Suppl. 177. For detailed analyses of this case see Hanna John, *Anti-Trust Immunities of Cooperatives*, Law and Contemporary Problems, Duke University School of Law Vol. 13, Summer 1948, pp. 488-504.

³⁵ 48 Stat. 608 (1926), 26 U.S.C.A. 101 (12) (1940).

³⁶ *Commissioner of Internal Revenue v. American Box Shook Export Co.*, 1946, 156 Fed. 2d 629.

either or both events the economic return and bargaining power to the individual cooperators is enhanced.³⁷

We have already made reference to the Rochdale tests of a true purchasing cooperative. We have also summarized the statutory requirements of an agricultural marketing cooperative under the Capper-Volstead Act, *supra*. With the exceptions of the basic partnership idea of one man, one vote, and of a too-high dividend allowance in view of our experience with low interest rates following the great depression of the 1930's, the statutory definition found in the Internal Revenue Code, Section 101 (12) of a so-called tax exempt cooperative appears to be probably the best definition of a "pure" or true cooperative yet evolved.

Frank Robotka recently called for new thought patterns on cooperatives and offered his analysis of "An economic concept of a 'pure' cooperative" in part as follows:

Every true cooperative represents an effort on the part of two or more autonomous units jointly to conduct, coordinately with each other, given operations essential to the economic activity of member units. It is the avowed purpose of true cooperators not to interpose a business enterprise in the usual sense between themselves and their market. In a technical economic sense, this can mean only that it is their purpose to function in their own capacities as sovereign units, that is, to perform designated functions or services as integrated with their individual economic pursuits.

The cooperative organization consists of the sum of the relationships and arrangements established among member units in order to effectuate their purpose. In an economic sense, these arrangements are designed to enable member units jointly to participate in the performance of their entrepreneurial functions with respect to the given activities which they desire to conduct in coordination with each other.

An integrated operation does not constitute an independent profit-making unit, that is, a "firm." Such an operation is a branch or a department of the integrating unit or, as is the case in a cooperative, of a group of integrating units.³⁸

Although Dr. Robotka's economic language is strange to the lawyer, the legislators and the courts, the concepts have their clearly recognizable counterparts in statutory provisions and

³⁷ An excellent and most comprehensive article dealing with taxes and bargaining power is: Paul, Randolph E. (Tax advisor to U.S. Treasurer, 1942-44), *Justifiability of the Policy of Exempting Farmers' Marketing and Purchasing Cooperative Organizations from Federal Income Taxes*, 29 Minn. Law Rev. 343-375 (May 1945). See also, *Tax Liability of Cooperatives*, Commerce and Industry Association of New York, Inc., New York, N.Y. 1946.

³⁸ Robotka, Frank, *Lego-Economic Implications in Cooperation*, American Cooperation, American Institute of Cooperation, Washington, D.C. (1946), pp. 522-533.

court decisions, including some judicially defined cooperative terminology.³⁹

The eight statutory requirements for a cooperative to gain tax exempt status under Internal Revenue Code 101 (12) are:

1. The association must be organized by farmers on a cooperative basis.
2. It must operate, as a marketing or purchasing agency or both, on a cost basis, ultimately turning back all net proceeds to member and non-member patrons on a basis either of quantity or the value of the products furnished.
3. Substantially all stock except non-voting, non-profit-sharing preferred stock must be owned by producers or purchaser-member patrons.
4. Dividends may not exceed eight percent or the legal rate in the state of incorporation, whichever is greater.
5. Only reserves required by state law, or reasonable reserves for any necessary purpose may be accumulated.
6. Neither the cooperative nor its member patrons may gain a discriminatory advantage on non-member business.
7. Non-member business must not exceed member business.
8. Agricultural cooperatives are limited in their purchases for non-member non-producer patrons to 15 percent of total business. Business done with the U.S. or its agencies is to be excluded in determining the right to exempt status.⁴⁰

My comment on the difference in definition of a cooperative by the economist and by Congress is that the former may be in part theoretical while the language of the legislatures and the courts is the final word; the ultimate in social control.

In integrating economic and legal thinking on Cooperative Corporations more exchange of points of view is imperative. It would be extremely helpful to have every school or department of economics place in its library a comprehensive legal dictionary; if possible, the 45 volumes called "Words and Phrases"⁴¹ which gives the judicially construed definitions of all lego-economic terms that have been defined by supreme courts of this country and England, and induce the students and professors to make extensive use of such materials.

Consumers and Cooperatives

The evolution of cooperative associations has been sketched as a struggle of farmers for increased bargaining power and the adapta-

³⁹ Jensen, A. Ladru, Terminology in Cooperative Corporation Law, Proceedings Section of Corporation, Banking and Mercantile Law, American Bar Association 1948, The Business Lawyer, Nov. 1, 1948, pp. 226-236.

⁴⁰ Note 35.

⁴¹ Words and Phrases, West Publishing Company, St. Paul, Minn. 1940.

tion of the non-profit corporation to off-the-farm marketing and purchasing operations.

The farmer must continue to work on his farm. He however, wants his off-the-farm operations to be carried on with as much efficiency as corporate organization, capital, and specialized skills can give, compatible with his retention of ultimate control in selecting directors, and of statutory partnerships organization for the limited purpose of receiving all pro rata net income above cost of operation of his non-profit corporate agent or trustee or both.⁴²

We have not mentioned that consumers, as such, remain largely unorganized in our dominantly corporate economy. One of the public relations tasks of cooperatives is to get the facts to consumers that marketing cooperatives can and do process and distribute food cheaper than was done, or can be done, by profit middlemen whom the cooperatives have replaced in part and are replacing.

Economic research supports this thesis⁴³ and a number of courts have taken judicial notice of this fact in various cases.

The Supreme Court of Wisconsin in the case of Northern Wisconsin Co-op. Tobacco Pool v. Bekkedal⁴⁴ wrote:

The reasons for promoting such (cooperative) legislation are generally understood. It sprang from a general, if not well-nigh universal, belief that the present system of marketing is expensive and wasteful, and results in an unconscionable spread between what is paid the producer and that charged the consumer. It was for the purpose of encouraging efforts to bring about more direct marketing methods, thus benefiting both producer and consumer, and thereby promoting the general interest and the public welfare that the legislation was enacted.

It is small wonder that the courts almost unanimously declare cooperative corporations to be in the public interest when by some enhancement of price to the sellers they still establish greater efficiency in processing and marketing operations and get consumer goods to the purchasers at reduced prices.

Cooperatives v. Middlemen

It is reliably reported as an economic fact that about thirty-five years ago middlemen handled practically all grain that went through the Minneapolis-St. Paul market, and that today the

⁴³ Bakken and Schaars, *Economics of Cooperative Marketing*, McGraw-Hill Book Company, 1937, pp. 199-200.

⁴⁴ Northern Wisconsin Cooperative Tobacco Pool v. Bekkedal, 182 Wis. 571, 197 N.W. 936, (1923).

farmers cooperative marketing corporations handle more than 20 percent of the grain which goes through that market, and with a substantial, exemplary savings to the farmer-cooperators.

This economic conflict between cooperatives and the middlemen whom they replace impinges at present in the concerted effort of middlemen dealing in agricultural products and production supplies to enlist all non-cooperative business in a campaign for legislation to tax patronage refunds of cooperatives.

The real problem in this regard is not the competition between the corporately associated farmers, and the middlemen dealers in farm products and production supplies, who directly compete with each other. Competition, if allowed to continue and if cooperatives steadily become more efficient, will eventually solve this problem in the good old American way.

The present problem of farm economists, cooperative corporation lawyers and other cooperative leadership is: how to marshal and disseminate most effectively the economic truth that cooperative corporations cannot and will not replace the bulk of non-cooperative, non-agricultural business if it remains efficient and operates in the public interest. The uninformed fear of non-cooperative businessmen who do not deal in agricultural products or supplies must be replaced with the quieting truth that a strongly organized cooperative agriculture will be a bulwark to a more freely competitive capitalistic democracy, and an anchor against the winds of "Statism."

The economic truth that non-cooperative corporate business can preserve its competitive position in most non-agricultural fields is borne out by the history of cooperative corporate growth in Switzerland and the Scandinavian countries. After fifty years of experience among the realistic Swedes private-profit corporations and non-profit cooperative corporations have found where each can best serve the public. Today they live happily side by side. Last year they teamed together to fight both nationalization and the Communists in the Swedish Riksdag.⁴⁵

Our problem is not only a better integration of economic and legal thought. It is a psychological and public relations one as well. The businessman who does not compete with agricultural cooperatives is one of the publics of the cooperatives. Good public relations

⁴⁵ Wallace, Ralph, Sweden—Land of Light, Reader's Digest, Aug. 1949, pp. 112-116.

require that this group of businessmen be educated to the truth of the finding by the National Association of Manufacturers: that cooperatives are "a legitimate form of private enterprise."⁴⁶

Bargaining Power of Industrialists, Laborers and Farmers

We have sketched the rise of bargaining power of labor unions and of farmers' cooperatives after gaining their legal right to organize for mutual self help by the Clayton Act of 1914. Since that time the bargaining power of labor, through broader and firmer organization, has grown much more rapidly and to a much greater degree than has the bargaining power of agriculturists.

Two and a half years after World War II, the average price of all agricultural products have fallen from their war time highs by about 30 percent, while the wages of organized labor have not fallen at all. This shows an unhealthy disparity between agriculture and labor. Neither have cooperatives yet grown strong enough to aid much in preventing harmful agricultural surpluses.

The pendulum of bargaining power has swung much further toward labor than it has toward agriculturists. Large corporations are still able to raise prices to absorb increasing costs and return a handsome profit. Truly "the rule of reason" and the Clayton Act opened Pandora's box of political pressurers and we struggle for a solution of momentous new problems.

Our economy has passed from the era of free individual competition when the simple common law outlawed all conspiracies in restraint of trade, to a legislative-judicial attempt to establish a workable allocation of bargaining power to non-cooperative corporate groups, labor unions, and farmers. The problem is tremendously big and complex.

The solution must be found in the integration of politics, economics, law, education and public relations with a spiritual aim toward the public interest in the minds and hearts of the leadership of every segment of the American economy. Otherwise, we will lose our heritage of freedoms, because of ignorance, selfishness, and a lack of diligence and cooperation among pressure groups of our society.

⁴⁶ NAM and Cooperatives, National Association of Manufacturers, New York, N.Y., 1946, p. 7.

INTEGRATING ECONOMIC AND LEGAL THOUGHT RELATING TO AGRICULTURAL COOPERATION

HAROLD HEDGES
Farm Credit Administration

A SEARCH of economic literature reveals that substantial attention has been directed to the inter-dependence of economics and the law. But our attention here is to be directed to a limited phase of economic activity—agricultural cooperation—and the legal considerations related to it. It is a subject to which considerable thought has been given in the past. Even so, the same anomalous situation remains today, though in less degree, that prevailed in 1927 when H. G. Moulton wrote in his preface to E. G. Nourse's book, "The Legal Status of Agricultural Cooperation," that, "The economist has been too little aware of the legal requirements and the lawyer too little versed in the fundamentals of economics and business for either to get an adequate grasp of the issues involved in the organization and operation of cooperatives."¹ Dr. Nourse's analysis of legal and economic inter-relationships in the field of agricultural cooperation, as presented in this book, is the most comprehensive of any to date on the subject.

In my opinion, the position Dr. Moulton expresses is a moderate one. In the not too distant past I had occasion to sit in a meeting of attorneys and accountants at which an economist discussed this matter of relationships between economics, law, and accountancy, and presented some quite advanced theory on the economic role of cooperatives. Judging from the discussion which followed, and from comments of listeners after the meeting, I was convinced there was actual resistance to the "radical" views of the economist. I trust that this is an isolated case not representative of the attitudes of lawyers and accountants generally. It is possible, of course, that more mature contemplation of the new ideas may have put them in a more charitable mood.

L. S. Hulbert² and other legal authorities have given us quite thorough and up-to-date analyses of legislative acts and court decisions which provide legal sanction for the cooperative corpora-

¹ E. G. Nourse, "The Legal Status of Agricultural Cooperation," the Macmillan Company, 1927, p. viii.

² L. S. Hulbert, "Legal Phases of Cooperative Associations," Farm Credit Administration Bul. No. 50, 1942; and subsequent quarterly summaries of cases relating to farmers' cooperative associations from same source.

tion and the cooperative way of carrying on business. There is not available however, for the past two decades, the sort of economic interpretation of these developments as was made by Dr. Nourse in 1927. I trust we can encourage some of our truly advanced students of agricultural cooperation—and they are all too few in number—to provide us with similar careful analyses and interpretations in the light of the many changes and advancements of the past twenty-odd years.

In approaching this subject of integration of economic and legal thought, I wish first to outline briefly the emergence among farmers of the cooperative pattern of business organization and some of the legal implications involved in that development. Cooperative efforts among pioneer American farmers were of the informal type—barn raisings, husking bees, threshing rings, and the like—combining social with economic objectives. There were no legal questions involved—no problems of corporate structure. In the early 1800's however, the fragmentary history of agricultural cooperatives reveals a few examples of cooperative business enterprise—cheese factories in New England, livestock marketing in the Middlewest, and others of like nature. Mutual insurance probably pre-dated all these cooperative marketing efforts.

No information is available regarding the extent to which these early cooperatives resorted to the corporate form of organization. Dr. E. G. Nourse³ holds the view that profit-seeking and cooperative corporations developed side by side, though at somewhat unequal rates of speed and in more or less exclusive fields. He offers the proposition, "that, while the ordinary business corporation was developing such structures and practices as it conceived to be advantageous to itself, elsewhere in our economic fabric other groups of people under other motives and circumstances were fashioning another pattern. Such groups, styling themselves cooperative, were trying to organize a naturally decentralized type of industry for the large-scale operations demanded in a scientific, commercialized, and capitalistic day, while at the same time preserving the personal independence and dynamic element of individual participation and reward which seemed to be threatened under some forms of modern industrialization."⁴

The course of developments which provide legal sanction for

³ *Ibid.*, p. 25.

⁴ *Ibid.*, p. 23.

cooperative corporations and recognize in law their distinctive economic characteristics is no different in essentials than that outlined by H. R. Commons in developing his theory of the going concern. To quote from him: "Meanwhile, there has been growing up, through the decisions of the courts on cases as they arise, the theory of a going concern. . . . The working out of the theory by inclusion and exclusion of transactions that had to be judicated in the decisions of disputes has been necessary in order to do justice to those who had associated themselves together, had built up a business, had assumed responsibilities, had trusted to the credit system, in the hope that their past and present business connection would be permitted to continue in the future. These hopes could not be shattered, else the whole fabric of society would come down. The courts and legislatures find them there, in the customary transactions of individuals, then recognize them, then authorize them, and the authorization is the security of the working rules. New hopes are built on these authorizations, and that which exists in the very nature of Man's transactions with his fellows comes to exist also 'in contemplation of law.'"⁵ In short, emerging organization structures, business practices, and the like which meet the test of economic soundness and social acceptance will in time receive the blessing of legal sanction by legislature or court.

Dr. Nourse reports⁶ that the first stirring of cooperative effort in the early years of the nineteenth century left behind no reminder of itself on the pages of our statute books. This preceded the period of general corporation laws, and cooperatives seeking the corporate form as well as other corporations were chartered by special acts of the legislatures. It is probable, however, that most of these earliest associations operated as unincorporated, voluntary organizations.

By the time of the Civil War, most of the states had enacted general corporation laws. Naturally, the cooperatives organized subsequent to such enactments desired to gain the advantages of the corporate form if they could do so without too great sacrifice of cooperative principles. Various devices were used to fit the cooperative structure to the corporate pattern. For example, in order to assure patron control, inherent in the one-man, one-vote principle, under a statute requiring voting on the regular share basis,

⁵ *Op. cit.*, Commons, pp. 152-153.

⁶ *Op. cit.*, Nourse, p. 29.

limitations were placed on the investment and therefore the voting per patron. Where the general law required distribution of profits according to capital investment, effort was made in many cases to proportion investment in the cooperative to use by each patron. Still another idea—unique in character and a forerunner of the marketing contract which received so much attention from legislatures and courts in the 1920's—was the maintenance (often referred to as penalty) clause in by-laws of Iowa farmers' elevators which pointed up the mutuality of interest of members by requiring contributions on a volume basis toward elevator expenses for grain sales made by members outside their own association.

Most of the early farmers' grain elevators and creameries organized in the Middlewest before the turn of the century and in the first decade of the present century were set up under general corporation laws with some of them adapting the various devices cited above to assure some conformation to cooperative principles and practices. During this period, however, pressure was exerted by farmer and other groups for specific statutes that would authorize incorporation of concerns that were mutual, reciprocal or cooperative in character. A mutual insurance law in New York in 1857, a cooperative association act in Michigan in 1865, and a Massachusetts law in 1866, were among the first. There was little to distinguish these early cooperative statutes from the general corporation laws, but they were indicative of an effort to overcome the lag between economic thought and legislative enactments relating to cooperative organization.

With the passing of time, the weaknesses from the standpoint of sound cooperative practice in the organization of the early farmers' elevators and creameries became more apparent. It was all too easy for such organizations to lose their patron ownership and control and revert to the ordinary corporation form and practices of business operation. In short, there was not at that stage of cooperative development the integration of legal and economic thought such that cooperative principles and practices were properly reflected in legislative acts. Most of the early acts (the California law of 1895 was an exception) provided such slight modification of general corporation laws that they were not conducive to permanency in cooperative organization structures.

The pattern of state cooperative laws passed in the period 1910-20, starting with the Nebraska and Wisconsin Acts of 1911, did a

better job of reflecting the bare essentials of good cooperative practice than had the earlier enabling legislation. Even so, none of these acts reflected the more advanced economic thought of that period relating to cooperatives. Most of them were however—and desirably so—drafted in quite general terms so that they permitted considerable latitude in application of cooperative techniques and experimentation with new ideas. On the other hand, they did not provide a very broad base of statutory rule to assist the courts in the interpretation of points of issue.

The California Act of 1895 is deserving of special comment since it was a radical departure from the cooperative legislation of that period, and reflected cooperative thought quite distinct from that accepted in other parts of the country. And yet it was quite a logical development. Generally speaking, business practices adopted by the grain and dairy cooperatives of the Middlewest held pretty much to the "purchase-and-sale" pattern of other business firms and adhered to going prices. The cooperative device so well known then as the "patronage dividend" was utilized for the distribution of the excess of the margins withheld beyond the amount necessary to cover costs. In contrast, the pooling idea was tried out and attained a high stage of development among California and other West Coast cooperatives. This gave emphasis to more exact proportioning of costs to services rendered and to the mutuality of interest among members. In this latter connection the marketing contract was developed and refined—an excellent example of integration of economic and legal thought. The California law (first the act of 1895 and then that of 1909) brought into the statute books the new idea of personal membership and of the proportioning of capital among members on the basis of volume of business done. Gradually the enabling acts of other states have been amended or new acts passed accepting the non-stock pattern or adapting the proportioning-of-capital idea to the stock form of cooperative organization or both.

Thus far my comment has been directed primarily to the problem over the years of gaining legal sanction for the cooperative form of business enterprise, and for the practices which give it force in accomplished objectives of cooperative endeavor. This has been an evolutionary process whereby ideas are translated into procedures and practices found to be workable, then the move to obtain positive evidence of public acceptance through legislative

enactments rather than to depend upon judicial decisions to gain acceptance. Even so, the body of state and federal legislation relating to cooperatives is complemented by a considerable bulk of judicial decisions. A major problem is the uncertainty which prevails pending legal acceptance of new ideas, practices or procedures, whether gained by legislation or judicial decision. Aside from the enabling legislation, many other legislative acts carry provisions which serve to interpret their application to cooperatives as distinct from other types of business organizations.

The fact that this economic institution—the farmer cooperative—has received legal cognizance, that its distinctive character and practices have been recognized in law and judicial decision, that its right to exist alongside other economic institutions has been established is evidence in itself that there has been reasonable integration of economic and legal thought on the matter. Perhaps the extent of the time lag between the development of new ideas or practices or procedures and their legal and judicial rejection or acceptance provides us with a measure of the degree of integration of thought. In any case, I am sure you will agree that we still fall short of the ultimate in cooperative practice. We are still in the process of seeking the right answers to problems of a changing, dynamic economic institution. Sound integration of economic and legal thought may speed up the evolutionary process and help to come out with timely and correct answers.

Preliminary to setting down some of the specific problems of cooperative organization and methodology presently deserving the attention of students of law and economics, let me outline some of the fundamental concepts of the cooperative from which these problems arise. The first of these fundamentals is the operation-at-cost idea—an idea not confined solely to the cooperative form of organization. A second fundamental concept is that of ownership and control by those utilizing the services of the organization. A third is the concept of capital as a loan fund in contrast to its significance in the profit corporation as the residual claimant of margins in excess of costs of the other factors of production. The emergence of these concepts during the last century or more and their application and refinement in cooperative business practice is in a sense a chronology of the development of economic and legal thought relating to cooperative organization.

The progress of agricultural cooperation to date is in direct pro-

portion to the basic thinking on both theoretical and practical aspects. Richard Pattee, first president of the American Institute of Cooperation, made this statement at the first Institute sessions in Philadelphia in 1925: "We who are managers and directors and you who are professors and scholars should be able to get a more definite, a truer, a more ample understanding of the essential nature of the cooperative form of economic organization. Only with such deeper understanding may this cooperative movement be brought to the more perfect practice we hope to contribute to our country's economic evolution."

Dr. Nourse had occasion to comment on the statement made by Mr. Pattee, which is quoted above in part, at the 1946 sessions of the American Institute of Cooperation.⁷ After pointing out the progress made in 20 years in developing "at least the basic frame of reference for such an understanding of cooperation as an institution," he added this thought: "We must bring the broader and more flexible methods of social science to bear on its solution, not the narrowly limited mechanistic tools of natural science." I trust that social scientists generally will heed the urging of Dr. Nourse and devote time and inquiring spirit to cooperation which he characterizes as "a distinctive economic and social philosophy for the better organization of an important fraction of, and particular functions in, the business of agriculture."

The constantly changing pattern of agricultural cooperation makes it important that continued attention be given to the resulting problems. As cooperatives grow in size and complexity, there arise more than the usual problems of scale associated with bigness. What devices, what procedures need be employed that there may be no serious departure from the fundamental concepts of cooperative economic organization? How bring about operation at cost? How give assurance that control finally rests with those utilizing the services of the organization, avoiding the tendency toward management control so common in proprietary business and industrial concerns? How may member-patron control be exercised intelligently and in the light of adequate information? How about such problems as pooling and pricing which are distinctively cooperative in character?

These and many others are practical problems affecting day-to-day operations and yet of long-term significance. Then there are

⁷ American Cooperation, 1946, p. 9.

the broader problems which concern public policy toward agricultural cooperation. What is its effect on the functioning of our capitalistic economy and the future of American agriculture? What is its place in an agriculture involving price supports and production controls? How do the operations of large-scale cooperatives square with current ideas on monopoly and restraint of trade? Are cooperatives meeting their responsibilities to the general public in a way that is consistent with the corporate privileges granted by statute?

Such problems as these need the thoughtful consideration of economist and lawyer as well as management to assure solutions which will be economically sound, legally acceptable, consistent with good public policy, and yet workable business-wise. It is not enough, of course, for each to analyze and examine as a specialist in his own field. The inquiry must be both within and between the specialized fields in order to assure synthesis of the numerous and often conflicting points of view. By such means, the lag between the development of new and economically sound ideas or procedures in the field of agricultural cooperation and their acceptance by legislature and court will be minimized.

DISCUSSION

H. E. ERDMAN

University of California

The Hedges and Jensen papers have traced, in an interesting way, the slow growth of the tendency for the courts to differentiate between farmers' cooperatives and combinations of businessmen organized as corporations. I clearly recall my own early contacts with the problem in Ohio during the period 1917 to 1921. I saw zealous district attorneys prosecute the officers of several small fruit and vegetable cooperatives under the Ohio Anti-Trust Act with never a mention of corporate dealers who were doubtless more influential as price makers than were the farmers. At about the same time the officers of a milk producers' bargaining association were called out of bed at midnight and jailed under the same Act, while the powerful corporate dealers were not molested.

Evolution in cooperative structure has come largely by successive minor departures from current practices, much as the automobile of today is the result of many successive innovations. Take, for example, the widely used revolving finance plan. In California, crude plans are said to have developed among some local orange packing associations about 1914 or earlier. During 1917 attorney George E. Farrand developed the plan now used to revolve the capital stock of the Fruit Growers Supply Company in

order to keep its ownership in the associations which used it. At about the same time the California Fruit Exchange, then a capital stock organization, developed an entirely different plan to "revolve" funds originally withheld from earnings to build up supplementary working capital. Gradually, a host of variants of these early plans have found their way into cooperative structures, all of them designed to keep ownership and control of the cooperative in the hands of the active cooperators.

In this process of evolution both the lawyer and the economist have tended to accept the current law and its interpretation as facts to be accepted and have sought to build on them.

Differences in approach or interpretation may very well arise out of training or background. Note how many lawyers or economists tend to reflect the thought patterns of their former teachers. Such influences may well be found to explain some of the "lags" in thinking about cooperatives.

Referring to Robotka's "economic concept of a 'pure' cooperative" Dr. Jensen says its language is "strange to the lawyer, the legislator, and the courts." I share the opinion of Professor Paulson that it is also strange to economists. It is true that the economists' concept of a "business firm" as "a profit maximizing unit" does not fit cooperatives without qualification, but the quoted characterization is likewise not acceptable.

THE FUTURE OF THE GREAT PLAINS REAPPRAISED

ELMER STARCH
Great Plains Council

“**T**HE Plains have certainly changed” is an oft repeated phrase as we compare the economic collapse of twelve years ago with the well-being of recent years. The truth is that the Plains have not changed but have merely been demonstrating the extreme variations in production which prevail in an economy geared to a critical climate.

This extraordinary economic zone is located between two great divides. On the west the boundary is well defined by the Rocky Mountain Watershed divide. On the east is a climatic boundary which we have failed to recognize until lately. The climatic divide is of greater importance than the continental divide since it is also the economic boundary. It is here that the ordinary concepts of economics fail under very great strain imposed by critical climate. This divide, according to Thornthwaite, falls on a line which can be drawn about straight south from Fargo, North Dakota. He calls it the zero line which marks the division between the moisture surplus areas and the moisture deficient areas.

About two-thirds of a million farm families live in the zone between these two divides. These families have found that this zone is governed neither by the rules of a consistently humid climate, nor by the rules of a consistently arid climate. The stresses and strains set up under these circumstances are so great that there have been numerous economic breakdowns during the last seventy-five years.

President Roosevelt appointed a committee to study the problems and report on recommendations for this great area as a result of the 1936 drought. In his letter to the chairman he said, “We are anxious that we leave no stone unturned in exploring and reporting on all the possibilities of this region.”

The Committee’s analysis was made under difficult circumstances, as adverse weather had caused a complete breakdown of the economic framework inherited from areas with a reliable climate. Long accepted principles of resource management had worked well on the Plains through the series of favorable years. Suddenly, however, when physical disaster struck, the economic

structure disintegrated. The situation was chaotic, and the Committee's comments were directed to an analysis of badly disrupted conditions and to some remedial lines of action. Great emphasis was placed on what might be phrased, "Keep looking," or "Learn about the laws of Nature." Throughout the report it is recommended that study of the climatic, physical and economic phenomena be stepped up. Very strong localized participation was urged in education and program building. Through the participation of great numbers, the people of the Plains have made marked progress in skillful development of programs. This is perhaps the outstanding feature of the era.

The title of the original inventory and outlook of the Committee report is, *The Future of the Great Plains*. It is a reassuring title, because it declares that the Plains have a future, and it characteristically expresses the philosophy of the Plains that "next year will be a better year." But the recommendations didn't say to wait with folded hands until a turn in the weather bailed out the Plains economy.

Quoting from the Report of the Great Plains Committee: "The problem of the Great Plains offers no simple solution. Yet enough is known about conditions and their causes generally throughout the region, and in detail with respect to certain parts, to permit immediate and vigorous execution of a program of readjustment and development. Further studies of details should proceed simultaneously with the execution of the program, but the beginning of action should not be permitted to await these studies, which should in fact be a part of the program."

The Future of the Great Plains is not a blueprint. It does not claim to be a plan or even a program. It does not set up specific goals to be reached at a given time, but it does say that by the best combination of research, education and concerted action, a suitable way of living can be devised. It does try to appraise the dim outlines of the economic framework into which the programs will have to be built. The President's committee went one step further and said, "The local people must join their efforts in appraising the situation and developing a program." To that end they suggested a Great Plains Council wherein the programs could be crystallized.

The following sentence from the Great Plains Report expresses well the central thesis of the efforts which people have undertaken in this area: "In a sense the Great Plains afford a test of American

ways of dealing with matters of urgent common concern." Throughout a twelve-year history, democratic and concerted effort has met and dealt with a series of urgent problems. The concerted effort has borne results such as I shall refer to later, but never forget that the problems and the remedies were made a common concern of all the people living in the area.

Many of the recommendations of the Committee have been fulfilled, some of them far beyond original expectations. The experience gained in attempting to make improvements has caused economists to probe into underlying principles with which improvement should be aligned. Some features are becoming evident. As yet, they cannot be stated with too much certainty. However, programs may be measured to some degree by whether or not they do some of the following:

1. Provide stability through reserves in as many forms as possible—moisture, feed, seed, money, credit.
2. Provide extraordinary control and protection for resources throughout the cycles of production.
3. Meet the longer than annual intervals between paydays.
4. Give full play to flexibility in cropping plans, repayment of contracts, and even to region-wide expansion and contraction.
5. Maintain the highest possible level of output per man hour to take advantage of peak conditions and low cost per acre or animal unit in order to decrease the rate of dissipation of reserves during periods of stress.
6. Help adjust the community pattern to a sparse population pattern.

We have in the foregoing principles some very obvious conflicts. On the one hand the Plains people as a community and the farm operators as individuals are trying to evolve principles leading toward stabilization, and yet it is held that flexibility is the key-stone for every farm operation and every contract, as well as for the economic structure of the whole Plains. It is a case of being flexible in order to achieve stability.

Management principles for the Great Plains farmer must be such that he can shift quickly and roll with the punch. He can have a central core around which to swing his day to day management but he may have to shift plans rapidly. He must have speed to do jobs when the weather is right. He must be able to build up reserves when the situation is favorable. For instance, he may be planning to cultivate 200 acres of summer fallow. The rules say that he is to complete the first operation by May 15 for best results. However,

when a particular spring season is dry until June 1, he must change his operating schedule so that with the first rain he will be ready to do his first summer fallow operation. He will be wasting \$200 if he does that first operation according to a fixed schedule, and furthermore, he would be exposing his land to wind erosion. Flexibility is the essence of management of other reserves, also, especially livestock feed. A rancher can have a stock pile of three winter's hay supply, but if a drought begins in May and persists on through July, it will be the better part of wisdom to reduce his herd.

The whole economy of the Plains must be able to expand and contract in accordance with the dictates of demand for certain crops. The cropping history of the Plains has a somewhat similar history to that of the cut-over forest lands, where a tremendously big crop is taken off once in two or three generations. In the interim periods, however, there seems to be no satisfactory or systematic set of management principles. In the Great Plains a series of big crops may be taken off the land frequently and therefore the periods of restoring lands and protecting them from deterioration come more frequently, but they are just as hard to handle as are those same tasks in a forest area.

In our appraisal of the future of the Plains, let us examine a few of the adjustments that have been made in the light of those recommended by the committee twelve years ago and try to fit them into this maze of apparently contradictory principles.

1. Moisture conservation is paramount and all practices leading toward this end are an essential part of farm and ranch operation. Several effective practices have been incorporated pretty generally into the routine practices of the farm operator. One of these is stubble mulch. Stubble mulch increases the absorption of water into the soil, which becomes a form of reserve; furthermore, it also protects the surface against wind action. The time required is drastically lowered, giving flexibility to the labor schedule to meet the season's climatic peculiarities.

It is the result of two avenues of research. The farm management experimenter was looking for cheaper fallow operations. The agronomist was looking for an effective device for increasing absorption of rain where it fell. So the two fields of inquiry merged and resulted in a formula which is not only cheaper by \$2.00 an acre, but better.

2. The shortage of water for livestock added to the shock of the

great drought of the early '30's. Water was a limiting factor in some areas rather than grass. Even the movement of livestock to the railway sidings was hampered by the lack of water along the cattle trails. Stock water development was listed by the Committee as one of the "on farm" programs. The original estimate was 20,000 reservoirs. A Plains-wide program of assistance in building stock water reservoirs was developed, and that program combined with the hard work of the ranchers was so effective that 300,000 reservoirs rather than 20,000 were built. Watering facilities are now available within $1\frac{1}{2}$ miles of most all grazing resources, and the reserve water supply is likely to hold out as long as the grass supply. The costs can be charged partly to insurance and partly to increased plant efficiency.

3. Dust storms and spectacular wind erosion appeared on every side during the 1930's; therefore, extraordinary emphasis was given to protection from blowing soil and the ways and means of restoring lands to permanent cover. In the course of eight years, 10,000,000 acres of wheat land have been restored to permanent grass. The restoration measure is not only one which applies farm by farm, but has community implications, inasmuch as a shift from more intensive wheat production to the more extensive grass production requires a drastic change in the size of the farm unit, and therefore every farm bursts out at the fences.

It is a protective measure, but its flexibility operates on a tremendously broad scope and has a one-way aspect about it. When the situation dictates a shift to wheat production, the change comes rapidly. The possibilities for returns are immediate. Manpower and equipment can be moved in readily. The larger ranch units can be broken into smaller wheat farms with the mere signing of a purchase contract (and at a good profit to the vendor). The grass lands can become wheat lands almost overnight. One county has increased its wheat acreage one hundredfold during the last eight years; mostly in the last four years.

When the economic and climatic situation calls for returning 10,000,000 to 20,000,000 acres to grazing use, it takes years to get a stand of grass and go through all the farm reorganization which accompanies this shift. It is costly and seems to require public assistance and certainly requires an outlay on the part of individuals from which they cannot hope to profit immediately.

The restoration of millions of lower producing acres of wheat

lands was a gigantic task well accomplished. But the Plains people are still in the process of learning the requirements which underlie flexibility on a grand scale. The community organization which accompanied the process of restoring land to grass was facilitated by the drawing off of manpower to the war industries. A study by Ward and Green entitled, *Geographical Differences in Production from Agricultural Land in the Northern Plains*, shows that by 1944 on a county by county basis a fairly uniform balance had been struck between the resources and the numbers of population. In the second round of restoration which is now before us, some of the factors which caused people to move to industrial areas will not be present, and therefore the balance will come less readily.

The accepted concept of marginality goes to pieces under the circumstances of a critically variable climate. Which acres are submarginal, those in central Kansas which produced an average of eight bushels during one ten year period, or those in western Kansas which produced an average of sixteen bushels in the ten year period immediately following? It is clear that we cannot use short time productivity records to determine submarginality. The determinations will be made on long time yield history and on the degree to which some soils are sensitive to wind action or water erosion. As these factors become established and accepted by resource managers of the area, then the adjustments to a particular type of production will be more permanent.

4. Utilization of water resources has advanced at a rapid rate, as the original appraisers of the future had hoped. Their emphasis was on small farm-by-farm irrigation. Records show that more than a million acres of crop land and meadow land have been put under irrigation in twelve years by the use of these small systems and it has been very largely of the type which added to the winter feed production of the ranch, or of the type which provided for the bridging of within-season droughts, as in the case of the pump irrigators of central Nebraska.

Irrigation systems both large and small must undergo a process of being adapted to a sub-humid climate if they are to give full results. First, they must be designed to give insurance against the effects of intermittent drought. Second, irrigation production must be fitted into an existing agricultural pattern. Third, the availability of water must be flexible.

Eight pilot projects which were established nine years ago to test

the usefulness of small irrigation projects of ten to twelve thousand-acre size scattered throughout the Great Plains embody the principle of an efficient design for farms which is comparable to the design for dams for safe and efficient water impoundment. Other principles, such as repayment according to productivity, and in some cases variable repayments, are being tried out. The integration of these projects into a surrounding agriculture has not been adequately tested as yet.

No mention is made in the Committee report of the gigantic water impoundments along the main streams of the Great Plains. However, in the course of fifteen years, engineering techniques have advanced to a point where one of the rivers of the Plains, the Missouri, will have a series of great water impounding structures. The experience in building earth dams derived from constructing the Fort Peck Dam, completed in the late '30's, has no doubt given impetus to additional great structures on the Missouri River. Large water-holding structures will no doubt be devised for other main streams as well.

5. Great stress has been placed on feed and seed reserves. The practice has been easy during these lush years; however, the original concept of feed reserves has undergone considerable revision. The cost of feed and the storage of feed should be balanced against the cost of maintaining a flexible livestock herd. The point of balance is still unknown.

It is being recognized more and more that a system of feed reserves is far more inclusive than having an extra stack of hay on each farm. Effective feed reserves cut clear across the board from the management of the open range, through winter grazing, through hay supplies, to well distributed stocks of grains, and in a larger sense includes the production of feed on irrigation projects.

There was some experience with stockpiles of grain during the late '30's and early '40's, when great supplies were under government storage. The distribution of these stocks did not conform to what the requirements would have been in case drought had come to any one community. Neither were the means devised whereby grains could be put in storage on a loan basis which would enable them to be withdrawn for feed purposes when and if needed.

We have also had some experience in efficient integration between production of hay on irrigation land and its use by the up-land rancher. When conditions are favorable, the feed stocks of an

entire area are high. The irrigation farmer finds that the sale value of hay is extremely low. When the entire area is short of feed, the prices will be high, and the cost to the rancher is sometimes excessive, but the irrigation farmer has no more than one year's surplus production to sell at those advantageous prices.

6. Land ownership, or at least systematic control of lands, was the point of greatest concern with those who studied the prospects of the Plains in the middle '30's. The whole system of ownership seemed to have broken loose. In fact, Dr. H. H. Finnell says that much land became a dust bowl hazard because of lack of finances and lack of continuing management of land.

The years of prosperity have obliterated the weaknesses which caused 30 to 50 million acres of land to go out of systematic management during the drought period. It appears, however, that some of the land tenure measures which have been introduced will be effective in keeping land under some sort of management under extremely adverse conditions. For instance, there are about 5,000 farms in the Plains area which have been put in the hands of farm operators under a variable repayment contract. Also most loan companies have introduced the principle of forbearance. Not all of the mortgage contracts have this provision clearly stated. In case of widespread income failure, some of the confusion of the '30's might be repeated.

Partial ownership has come to be important in many areas. By means of partial ownership, the operator shifts some of the fixed cost to a second person. In some cases the second person is the government or some other organization which can forego returns from the land for indefinite periods, providing that the average is maintained through higher returns during favorable seasons. A methodology in the protection of equity, security of occupancy, and continuity of management is slowly coming to undergrid the Great Plains economy.

7. Institutional devices for protecting and managing resources are discussed at length in *The Future of the Great Plains*, for it looked as if individual managers were unable to cope with problems which were so widespread. The suggested devices include zoning and two new instruments, a district for the control of erosion and the grazing association.

Zoning embodies many of the principles which are required in a Great Plains instrument for control. However, it lacks the feature of flexibility.

Grazing associations have their application in areas which are quite obviously and permanently given over to range use. The grazing association provides for flexibility in that it envisages rapid changes of livestock numbers to coincide with the seasonal forage production. Flexibility in annual rental fees through the use of the cow-month basis is spreading.

The districts "for wind erosion control," such as were enacted in Texas, have been superseded by the conservation districts. Some of the state conservation district laws do provide for some ordinances which will encourage or discourage certain trends in land use. When a conservation district through experience evolves control devices, the district can become the medium for a systematic shift in land use that will no doubt some day include the measures which will enable manpower to come into an area and quickly convert it to wheat, but with certain protective restraints. These districts can also provide for a reserve fund, or measures which will quickly restore the grass cover on certain lands. If such measures are eventually devised, community disorganization will not be as great as it is at present.

8. Adaptation of public and private facilities to a sparse population pattern with its attendant small trading center, is perhaps the area of least progress. We have just lately begun to recognize that sparse population is a permanent and modifying characteristic of the Plains, and that the entire system of public and private services must gradually, even though painfully, adjust. Some of the states have initiated laws providing for redistricting of schools, but so far the implementation of these laws has met largely with failure.

I have recited a few instances where the economic strength of the Plains has increased through programs of improvement, but let me refer you again to that key sentence in the President's Plains Committee Report: "In a sense the Great Plains afford a test of American ways of dealing with matters of urgent common concern."

The Plains people have learned much about methodology of practical interpretation and concerted approach. The confidence of the future lies as much in the practical interpretation and concerted approach as it does in having found excellently adapted practices and in having seen major programs put into effect. It is for this reason that I want to give the five stages which seem to be essential to full cooperation in "dealing with matters of common concern."

1. Each of the problems to be attacked must be isolated so that the people may see specifically what its components are and what its effects are, so that it will be a clear-cut and manageable segment in the program of modification.
2. The remedy as well as the problem must be thoroughly understood by thousands of people. Such understanding results from a thorough-going discussion where farmers themselves work out the means for initiating the remedial measures.
3. The remedial measures must be tested as far as possible by the criteria of the area.
4. An inventory must be taken of the facilities at hand for doing the job. Many times the job involves public as well as individual interests and this point must be recognized by law or by the administrative adaptation of a program.
5. Concerted action must be obtained between the agencies that are concerned with assisting farmers in the process of adjustment and modification.

One may say that the foregoing stages are ways and means to overcome at least four major hurdles:

1. Individual adaptation, whereby managers of the resources set aside methodologies which have been imported from other areas or carried over from earlier years.
2. Institutional adaptations, which in many ways are harder to evolve than individual adaptations, because they require group action, changes in laws, etc.
3. National cognizance of the problem must be obtained, since all agricultural production has national implications.
4. Organizational geography tends to shape up according to convenience of travel and grouping of adjacent states. Ofttimes centers of problems are not only cut in two but into several pieces, so that they become incidental and fringe problems to groups which are considering studies of problems, educational means, or action.

In the re-appraisal of the future of the Plains, one must recognize that progress is being evaluated in terms of principles and measuring sticks which have not been fully crystallized, and also, that the tests must come over a long period of time, for what seems like progress in one era may prove to be just another weak link in the one following.

There are those who believe that the economy of the Plains could withstand the strain of a drought of the intensity of the '30's. That conclusion is by no means supported by the evidence. There are also those who maintain that it is impossible to devise enough adaptations in the physical field or to adjust our management con-

cepts to a point where the economy will be anything but a continual repetition of "boom or bust." However, the evidence is here to indicate that the economic structure is less likely to go to pieces under severe strain than it was when the area entered into the great drought of the '30's. We must remember that the Plains economy is subject not only to great droughts affecting the whole area, but to localized droughts which are in effect in some part of the Plains most every year, and the economic structure may be strengthened so that at least it could cushion minor droughts.

The Plains people have become less and less a "next year" people. They are recognizing that they are resource managers who must figure in terms of a long time performance. They can see by the statistics that if they can live in the Plains for twenty or thirty years, they will have a better than the national average income. So they are devising every means and using every skill that science and experience can produce in order to manage their resources and finances in such a way that they can maintain a high level of living and yet protect their resources.

DISCUSSION

R. B. TOOTELL

Montana Extension Service

Mr. Starch mentions frequently the word "flexibility." Probably in no other part of the country is flexibility in farm organization and operation as essential to the achievement of *stability* as in this vast semi-arid country known as the Great Plains

Particularly in the early part of his paper, it seems to me that Mr. Starch is too optimistic. For instance he says, "The Plains people are no longer 'next year' people." I doubt if this can be very adequately demonstrated until the next series of drouth years. The Plains people, are, as Mr. Starch points out, becoming more in the nature of "resource managers." However, it seems to me he infers they have achieved a higher degree of accomplishment in this direction than I am presently willing to concede.

I quite agree that if the people of the Plains can live here for a 20 or 30 year period they will, over that period, have incomes averaging higher than the national average. A real problem of Great Plains farmers and ranchers is, therefore, how to weather the lean years *in a satisfactory manner*, in order to take advantage of the high income periods.

Reserves in the form of moisture, feed, seed and capital accumulated during good years is undoubtedly the key to weathering the adverse periods. I am inclined to place greater emphasis on capital reserves and less on the others than Mr. Starch. At the same time I should like to point out

that the high income tax rates of recent years seriously impair this safety factor. The "net after taxes" is not going to permit "averaging out income" as we formerly attempted to do. Cash or readily convertible securities are important, but other types of capital reserves are equally important. Debt free ownership of the farm or at least a modest debt is one of the best reserves possible.

This matter of reserves leads logically to crop insurance. Farmers in no other part of the country stand to profit as much over the long pull from crop insurance as do those operating under the highly variable conditions of the Plains.

For many years there has been a trend among western ranchers toward a cow and calf type of operation. It is too inflexible. When a dry year with little forage production occurs the operator may have to dispose of a high percentage of his breeding herd and he is not in good position to expand when feed supplies become more abundant. A cow-steer type of operation gives far more flexibility. With the advent of very favorable grass years the steer operation permits rather rapid expansion.

Because there has been a considerable expansion of the cow and calf type operation we may expect a relatively heavy reduction of livestock numbers when drouth conditions return. Encouraging a return to a higher percentage of steers before drouth comes will be in the interest of operators on those ranches now following the cow and calf system.

Mr. Starch has indicated that considerable land use adjustment is necessary. Some of the obstacles that stand in the way of this adjustment are:

1. Under present conditions of favorable moisture and prices, farmers are not voluntarily going to give up the prospective income as a contribution to the cause of conservation.
2. The land is capitalized on too high a basis.
3. There is an acute shortage of grass and legume seed of adapted varieties.
4. Real estate taxes usually lag years behind any adjustment in land use.

There have been nine years in most parts of the Plains during which dissatisfied farmers and ranchers could sell to advantage. Because of the alternative opportunities prevailing, practically all of those on the land now are here by choice. They like the Plains and more than ever before they are spending money to improve their homes and make them permanent. The rugged conditions of the '30's constituted the most severe kind of test. For the most part there has been a "survival of the fittest." The future of the Great Plains rests primarily with the people themselves. They still have many adjustments to make. I personally believe it improbable that a drouth as serious as that of the '30's will occur again during my lifetime. I believe it even less probable that severe drouths of the future will be accompanied by the disastrously low prices of the great depression. The Plains already has experienced the worst! It is now far better prepared to meet future emergencies.

DISCUSSION

GEORGE MONTGOMERY

Kansas State College

The paper presented by Mr. Starch outlined effectively two of the basic economic problems of the Great Plains: the systematic control of resources throughout the productivity cycle and the development of social and political institutions in an area of sparse population. Toward the solution of problems of production and efficient use of resources from the individual's viewpoint, substantial progress has been made. In devising effective social control of resources throughout the cycle, the record of accomplishment is not as good. Soil conservation, grazing programs, control of wind erosion, and flood control, indicate progress in protecting society's interest in the resources of the Plains. But much remains to be accomplished. The recent war period, accompanied by good yields and high prices, encouraged the use of land for immediate gain of individuals without adequate regard for the maladjustments which may follow.

It has been pointed out that, "Plains people are no longer a 'next year' people. They are becoming resource managers who figure in terms of a long-time average." This is true, but they still figure in terms of a long-time average that will provide the largest individual income. Adequate consideration is seldom given to the social problems arising from the actions of individuals. The income obtained from wheat during the years of high yield and high prices was probably many times the income to be expected from grazing, and the annual net income may have been larger than the current market price of the land. Unfortunately, this maximization of individual income has not contributed to the stability of the agriculture of the region. We are now faced with the problem of shifting these extra acres from wheat back to grass in order to prevent reappearance of the specter of the dust bowl.

The problems of physical production in the Plains area were solved effectively under a system where the motivating force was private gain. The traditional independence of the pioneer, and the necessity for speculative gains as a reward for enduring the hardships of the frontier created throughout the Plains a philosophy of individual freedom in the use of land. The emphasis upon the independence of the individual in the right to use land as he chose, and the economic and political institutions created in the pioneer days have not provided a favorable framework for solution of problems of wind and soil erosion, problems of surpluses and fluctuating prices, and instability resulting from high natural risks. In the past much of the research in the Great Plains has been directed toward improving the efficiency of the individual and increasing personal incomes. With the fluctuations in yields, prices, and incomes, which characterize the Plains, society cannot afford to rely primarily on the self-interest of individuals to provide answers to problems relating to efficient use of resources and stability of income. The task ahead is one of developing techniques or organi-

zations for effective group action. Land-use classification and zoning are techniques which might be utilized to prevent excessive expansion of wheat acreage in periods of high yield and high prices. The soil conservation district, the grazing district, the irrigation district, are examples of group organization adapted to area and regional problems. Reliance upon group organization and local leadership should provide a more stable and efficient agriculture than can be achieved by monetary payments

The paper providing the basis for this discussion refers to the "adaptation of public facilities to a sparse population as the weakest link." It is not only the weakest link, it is the one to which the least attention has been given. There has been a decrease in farm population in the fifteen years since "The Future of the Plains" was first considered. There has been a substantial migration from farms to the county seats and village communities. Apparently no one knows the actual extent of this migration in areas such as Western Kansas. Likewise little is known about the reasons for this movement, or to what extent the farm family has improved its lot by moving to the county seat or village. There has been concern about wind and soil erosion, but little attention has been given to problems arising from the movement of farm families. Inadequate appraisal has been made of the impacts of these movements on the schools, churches, and other social economic and political institutions. Relatively little is known about how the movement of the family to town will affect the size, organization and efficiency of the farm. Will it mean complete abandonment of livestock and poultry enterprises on those farms where the family resides in town? How will this migration affect the educational programs of 4-H Clubs and vocational agriculture? Substantially more information is needed on these trends which have such an important bearing on the future of the Great Plains.

FARM BUSINESS SURVIVAL UNDER EXTREME WEATHER RISKS¹

RAINER SCHICKELE
North Dakota Agricultural College

THE vulnerability of farm income to fluctuations in business activity and prices is notorious. In high weather-risk areas, the effects of extreme variability of weather are super-imposed upon the uncertainties and erratic performances of our national economy. The Great Plains are such a high-risk farming area par excellence, and I shall draw some illustrative material from that area.

John Wesley Powell, in his famous "Report on the Lands of the Arid Region of the United States" (1878), warned against the folly of allowing this area to be homesteaded. He visualized the settlement of most of the Plains in "pasturage farms" of not less than 2,560 acres in size. He considered irrigation the only dependable basis for arable farming in this area.²

During the succession of ten drought and pest years in the '30's Major Powell's report was brought to light again. People began to wonder; perhaps this settlement of the Great Plains was really all a big mistake. Then, during the '40's, years of exceptionally good weather and prices have given Great Plains farmers an unprecedented prosperity. Many debts have been paid off, farms enlarged, houses modernized. Yet, farmers ask themselves: How long will it last? Could we survive another drought like the '30's?

Such a long and severe drought might not recur again during this century; or it might start next year. It might be even longer and more severe; or it might be shorter and less devastating. Or the weather might, for a spell of years, hover more closely around some long-time average. Who knows?

Fundamentally, with respect to the time dimension relevant to planning and decision-making by individuals and groups, the weather factor in this region represents an uncertainty of a kind that seems to preclude actuarial determination of annual budgetable costs

¹ Abstract of a paper presented at the Annual Meeting of the American Farm Economic Association, Laramie, Wyo., Aug. 19, 1949. The full text may be obtained from the author upon request. Journal paper of the North Dakota Agricultural Experiment Station, Project P143

² 45th Congress, 2d Session, House of Representatives, Ex. Doc. No. 73, April 3, 1878, p. 22.

of *weather risks*. This may mean that a "sound" crop insurance program with premiums balancing indemnities over a *reasonable* time span (which could hardly exceed 15 years or so) might prove impossible; that the utmost thrift of individuals during good years would yield reserves insufficient to tide the farm business and family over long years of crop failures; that the nation might have to come to the rescue of Great Plains agriculture once or twice during a generation; and that if we fail to adapt our economic institutions to the weather uncertainty, we might fail to preserve dry-land farming in the Plains—or preserve it at a staggering social and human cost.³

Problem I: The Bunching of Poor and Good Years

The yield variability itself, high as it is, does not constitute the core of the economic problem. It is the bunching of poor and good years into long periods and their universal incidence that taxes the farm economy of the Plains. Let me illustrate.

In North Dakota, wheat yields averaged 11.8 bus. for the 13 year period of 1933–45. During the first five consecutive years, wheat yields were more than 30 percent *below* that average (<8.3 bus.); during the last five years, they were more than 30 percent *above* the average (>15.3 bus.), and only during the three years in the middle did they fall within 30 percent of the average—a very wide range at that, compared with yield variabilities of major crops in other farming regions.⁴ Every year since 1941 (i.e. eight years) wheat yields have been 20 percent or more *above* the 25 year average of 11.9 for North Dakota.⁵

If these wide yield fluctuations were fairly well dispersed over time so that poor and good years would tend to alternate, the economic problems of income instability would be greatly eased. People could then build up sufficient reserves in cash and kind during one or two good years to tide them over one or two poor ones. Premium rates for crop insurance would be much more amenable to

³ For the sake of simplicity of exposition, I assume that most of the present dry-farming area should remain in farming for optimum resource allocation.

⁴ During the same period corn yields in Iowa fell below 30 percent of the average in only two years, and exceeded 30 percent of the average in none of these years.

⁵ Over a 530 year period in North Dakota tree-ring studies suggest that there were 22 dry periods and 24 wet periods of three or more years, and only five dry and five wet periods of one or two years. The longest dry spell was 16 years (1782–1801), the longest wet spell was 39 years (1664–1702). See G. F. Will, *Tree Ring Studies in North Dakota*, *N. D. Agr. Exp. Sta. Bul.* 358, April, 1946, p. 23.

actuarial determination so that for any 10 or 15 year period indemnities could be made to balance premiums. An ever-normal granary program could be operated at less cost.

As it is, the cumulative economic effect of the bunching of good and poor years into periods of irregular length is highly disturbing to the planning of farmers and agencies. It results in widely dispersed probabilities of yield expectations and high individual and social costs incident to that uncertainty, in the form of bankruptcies and human despair or sporadic relief action from outside the region.

Therefore, one of our chief problems is to minimize this cost of uncertainty, to cushion the impact of a series of poor years upon the farm economy, and to build all kinds of "reservoirs" for catching as much as possible of the "rainfall profits" of good years.

The geographic incidence of poor crop years tends to be nearly universal throughout the region (in contrast to the incidence of hail, frost, fire or life losses for instance). This results in: (a) The difficulty of spreading the total annual cost of yield risk among the producers in a locality or even the region and expecting them to be able to carry such cost through the whole sequence of poor years; and (b) the need for carrying extremely large reserves of physical stocks and liquid assets, because the majority of Plains farmers will depend upon such reserves *all at the same time*. Just imagine what the size of the reserves of a fire insurance company would have to be if at irregular intervals 80 or 90 percent of all the insured houses would burn down simultaneously.

The bunching of the poor years and their universal and simultaneous incidence throughout the region suggest that it might be cheaper and more feasible to allocate part of the risk cost outside the region rather than make the region carry it all.

Problem II: The Critical Limits of Survival

The economic problems created by yield fluctuations and the bunching of poor and good years are aggravated by the structure of the farm business. Most farms are of the family type, varying in size roughly between one-half and two sections in grain areas, or 50 and 200 cows in grazing areas. The bulk of the labor force comes from the operator and his family and constitutes a fixed cost in the enterprise.

Rigidity of operating and living costs: If in a succession of poor

years net income available to the farm family is reduced below the minimum living requirements, the survival of the farm as a going concern and as a family home is threatened. Hence, it is not enough to consider only the amplitude of income fluctuation. Even more important are frequency and extent of income deficits below the level of minimum operating and living requirements of the farmer.⁶

For instance, if the net income is \$10,000, a poor crop slashing that income to one-third does not endanger the survival of that farm family; but if it is \$3,000, an income reduction to one-third—particularly if prolonged over several years—will wipe out farm and family. Plains' farmers have often been called gamblers; but gamblers rarely play for their homes as stakes.

The crucial problem of weather uncertainty for the farmer is to reduce the probability that crop hazards will cut his income below the critical limit of survival. To illustrate, let us construct a model of a typical wheat farm in the Northern Plains.

In this simple model, the effects of output variations due to weather from 67 to 125 percent of a long-time "normal" upon the disposable cash farm income are demonstrated.⁷ Such variation in output has but little influence on input costs; hence, they are held constant. An *unencumbered owner-operator* of average ability and with a family requiring about \$2,400 of living expenses to maintain a minimum adequate standard can just squeeze by on a two-thirds crop; a *moderately encumbered owner*, under present rigid debt and tax obligations, falls 30 percent below the critical family maintenance level—which he might manage for one year by postponing replacement of clothes and other temporary retrenchments in consumption expenditures, but which over a period of years will inevitably result in loss of the farm; a *heavily encumbered owner* can just squeeze by on a "normal" crop, but is completely at the mercy of his creditors in case of a two-thirds crop.

It is the *location of this critical limit of family maintenance* and the *reduction of the probability that a farmer's disposable income might fall below this limit*, which constitutes the heart of the income stabilization problem in the Great Plains.

⁶ We consider here the price level to remain constant.

⁷ Note how the relatively fixed cost structure affects the "net operator's income elasticity with respect to yield." A 30 percent reduction in yield (from normal) results in a 50 percent reduction in net income for an unencumbered owner, 60 percent for a moderately encumbered owner, 90 percent for a heavily encumbered owner—using rounded figures. The implication of this relationship is not sufficiently realized by economists who are developing the marginal analysis of production functions.

TABLE 1. TYPICAL NORTHERN PLAINS WHEAT FARM^a
(Assuming 1946-47 price level)

Item	Unit	"Good" Conditions	"Normal" Conditions	"Poor" Conditions
Wheat yield per acre	Acres	480	480	480
Cash receipts	bu.	14 8	11.8	8.0
Cash operating expenses	\$	8,700	6,900	4,600
Property taxes, insurance	\$	1,700	1,700	1,700
Net Cash farm income	\$	300	300	300
	\$	6,700	4,900	2,600
A. Unencumbered Owner				
Disposable Cash income	\$	6,700	4,900	2,600
B. Moderately Encumbered Owner				
Debt payments on 5% ten-yr. mortgage of \$7,200	\$	900	900	900
Disposable Cash Income	\$	5,800	4,000	1,700
C. Heavily Encumbered Owner				
Debt payments on 5% ten-yr. mortgage of \$10,000; 6% short-term loans of \$2,000 over two years	\$	2,310	2,310	2,310
Disposable Cash Income	\$	4,390	2,590	290
Minimum Requirement for Adequate Family Living Standard ^b	\$	2,400	2,400	2,400

^a Adapted from W. D. Goodsell et al, *Typical Family-Operated Farms, 1930-47*, B.A.E.F.M. 55 and 70, U.S.D.A., Washington, D. C., April 1946 and Sept. 1948.—This is a 480 acre farm, with a real estate investment of \$12,000, and machinery and livestock investment of \$4,500.

^b For a city worker's family of four, the estimated costs of a minimum adequate family budget was around \$3,200 at June 1947 prices (See U. S. Dept. of Labor, B.L.S. Bul. 927, *Workers' Budgets in the United States*, March 1948, p. 22.) For a typical farm family of five or six a budget of \$2,400, or 75 percent of a city family of four, might be expected to provide a roughly comparable level of living.

This proposition needs emphasizing. The problem is *not* to stabilize income near a long-time "normal" level. It is rather to *prevent the disposable income of any competent and honest farmer from falling below the critical level of farm and family maintenance* as a result of weather and price factors beyond his control. *Any income variation above this critical limit, however wide and erratic, does not seriously jeopardize the region's farm economy.*

Character of Income Variability: To get a sense of the character of income variability, take North Dakota as an example. *In terms of 1947 dollars*, gross cash income from marketings per farm averaged \$4,600 for the 25 year period of 1924-48, and ranged from \$1,380

in 1932 to \$10,240 in 1947,⁸ or from 30 to 220 percent of the average (see Table 2). All years with a gross cash income 33 percent or more below average were consecutive, lasting 10 years.⁹

TABLE 2. FREQUENCY AND LENGTH OF VARIATIONS IN GROSS CASH INCOME PER FARM, IN 1947 DOLLARS, NORTH DAKOTA, 1924-1948, 25 YEAR PERIOD

Range Limits		Number of Years	Percent of all Years	Length of Consecutive Years
In Percent of Average	In 1947 Dollars			
Under 50%	2,300	8	32	8
Under 67%	3,100	10	40	10
Under 80%	3,700	12	48	11
80-120%	4,600 average	6	24	2, 3, 1
Over 120%	5,500	7	28	7
Over 133%	6,100	7	28	7
Over 150%	6,800	6	24	6

What does this mean in terms of the critical limit of farm business and family survival? These figures represent gross cash incomes from marketings out of which all operating and living expenses as well as debt and tax payments had to come. State averages are notoriously inadequate to answer this question satisfactorily. We hope soon to get income distribution estimates which should throw considerable light on this problem of critical limits. In the meanwhile, we might get a very rough idea from the material at hand.

Under a parity ratio of around 95, and under "normal" crop conditions, we can assume that something like one third of the cash receipts from marketings is required to meet current operating expenses and taxes on the majority of North Dakota farms. The parity ratio for the 25 year period was 94. Let us assume that on the average about \$1,500 was required from the \$4,600 to cover these expenses, leaving an average disposable income (except for income tax) of \$3,100 to an *unencumbered owner-operator*. If necessary consumer expenditures for a typical farm family required \$2,400 (in terms of 1947 prices), \$700 would have been available on the average for savings and improved living.

⁸ Based on data from "The Farm Income Situation," B.A.E., U.S.D.A. Cash receipts are divided by the U. S. "Prices Paid" Index, 1947=100.

⁹ The variability of *net* income is, of course, much greater than of gross income. See "Risk-Bearing in Agricultural Production in the Great Plains—Based on a Study of 246 Kansas Wheat Farms," B.A.E., U.S.D.A., July 1949. (mimeo.)

The crucial question now is: In how many years and how far did the disposable income fall below the critical limit of family maintenance for unencumbered and encumbered owners? In 13 out of the 25 years, an *unencumbered owner-operator* with a period average of around \$4,600 gross cash income could not have maintained family living expenditures at \$2,400. A *moderately encumbered owner* could not have maintained that living level and an annual debt payment of \$900 in 16 years of that period, of which 15 were consecutive. He would have had a *negative* disposable income in eight consecutive years (1931-38). It is estimated that around one third of all North Dakota farmers lost their farms through foreclosure during the '30's, largely as a result of these conditions.¹⁰ Most farmers were forced to reduce operating and living expenses way below requirements for efficient production and minimum adequacy in family living—to the detriment not only of themselves, but of community welfare and the land as well.

The cumulative effect of the bunching of poor and good years is demonstrated in Table 3. An *unencumbered owner-operator* of an average size farm who started farming in 1924 would under the assumed conditions have entered the '30's with a saving of \$2,100 (of 1947 purchasing power). During the next 11 years, he would have had to go into debt for \$17,500. From 1941 on, had he kept his expenses at the \$3,900 level he would have saved by 1945 more than sufficient (\$17,900) to repay the incurred debt, and would have wound up by 1948 with a net saving over the 25 year period of \$17,350. For an *encumbered owner*, the last 25 years would have wound up with a net deficit of \$5,100 in 1948. In order to maintain the assumed expenditure level, he would have had to borrow between 1926 and 1940 \$32,800—a sum quite beyond his reach. Still, his deficit of \$5,100 might be wiped out by two or three more good years so that he might get into the clear over a 25 to 30 year period. Then, again he might not. This is much too long a time-span for an individual farmer to plan his finances. There can never be any certainty that the deficits will be offset by surpluses within any predetermined time period relevant to individual planning and decision making. The implications of these characteristics of income variability are far reaching.¹¹

The Goal

These characteristics of weather uncertainty and yield variations, in conjunction with price uncertainty and the closeness of the long-time average income level per farm to the critical limits of business and family survival, suggest the following over-all goal for remedial measures to stabilize the farm economy in high-risk areas:

We must find ways, through a combination of individual practices and public policies, that will enable any competent and honest farmer operating an adequate-size unit to ride out periods of drought and very low incomes without starving his family, robbing his soil and losing his farm.

We must discover and apply new farm management and business practices, cooperative methods and government programs that will provide an adequate minimum of economic security over the years for any farm family willing and able to do its share, in face of extreme weather and price hazards.

More specifically: *when, due to no fault of the farmer, his product value falls below the critical limit of necessary farm operation and family maintenance, he should have an opportunity to draw upon sufficient resources from within or outside his enterprise to maintain a minimum adequate level of expenditures.*

As much of those resources as possible should come from *within* his farm unit, from reserves and insurance premiums that he can reasonably be expected to build up and maintain economically on his own. Beyond this source, additional stocks and funds will be needed by many farmers during one or more periods in their active years which will have to come from *outside* their enterprise, in the

form of crop insurance indemnities, credit of various kinds including debt and tax deferments, and in extreme emergencies even public grants in aid (of which price supports represent one kind).

From the viewpoint of resource allocation, the disruption of an adequate-size farm as a going concern under average management due to weather hazards entails a social loss; from the viewpoint of personal income distribution, the disruption of a competent and honest farm family through prolonged deprivation and eventual dispossession as a result of weather hazards spells undeserved hardship and drags a long train of social costs, unrest and frustration in its wake.

The goal is not primarily to reduce yield uncertainty, but to reduce the impact of yield uncertainty upon the security of the farm economy. The goal is not to stabilize income at some long-time average level, but to place a floor at the critical level of farm and family survival. The goal is not to depopulate the high-risk areas down to the Indian level of man-land ratio, but to secure a pattern of farm sizes where each unit is large enough to apply modern production technology and to support a family at acceptable standards of living *under conditions of long-time average yields*.

Remedial Measures

Crop Insurance: The first question might well be, whether the physical yield uncertainties can be converted to "known risks." Frank H. Knight points out: "when the technique of business organization has reached a fairly high state of development, a known degree of uncertainty is practically no uncertainty at all, for such risks will be borne in groups large enough to reduce the uncertainty to substantially negligible proportions."¹² He distinguishes between three different types of probability judgments: "a priori probability" as exemplified by throwing a perfect die; "statistical probability" determined by mass observation and classification of instances in frequency distributions, e.g. fire hazard for buildings; and "estimated probability" derived largely from our intellectual capacity "to form more or less correct judgments about things," from "an intuitive sense of value," such as the estimated probabilities of various relevant events upon which an entrepreneur bases his business decisions.¹³ Only the first two types of probability

¹² F. H. Knight, *Risk, Uncertainty and Profit*, p. 47.

¹³ *Ibid*, p. 225.

can be expressed in terms of actuarial valuation of risks. Certain specific meteorological components of the factors determining crop yields could conceivably be evaluated in terms of "statistical probability."¹⁴

It has been estimated that fairly accurate yield histories over a 25-30 year period would be required in order to establish premium rates which would approximately balance indemnities over such a period.¹⁵ The principles involved here may well have much broader socio-economic significance. The unevaluated *total* uncertainty of a given type of occurrences (in this case wheat yields) is broken down into two parts: (1) one part represents a valuated risk determined by limited statistical observations of certain occurrences (e.g. yield deficiencies) over a relatively short period (e.g. 10-20 years)—the cost of this "*partial risk*" being borne by the "insured"; and (2) the other part represents "*residual*" uncertainty for which we have no way of calculating probabilities and hence cannot determine its risk value—the cost of this "residual" uncertainty being borne by society whenever it rises above the individual's ability to bear.¹⁶ The contractual provisions establishing premium and indemnity rates, therefore, must rest upon a combination of Knight's "statistical" and "estimated" probability judgments—with a strong accent on the latter.¹⁷

Grain, Feed and Cash Reserves: Because of the great uncertainty regarding the length of the good and poor periods, the width of the gap between poor crop output and critical survival limit, the movement of future prices, and the technical limitations of farm storage, I suggest that emergency grain and forage reserves on individual farms can hardly be expected to do more than compensate for a partial

¹⁴ G. Blumenstock, Drought in the U. S. Analyzed by Means of the Theory of Probability. *U.S.D.A. Technical Bul.* 819, April 1942, p. 61.

¹⁵ Summary Report of the Wheat Crop Insurance Consulting Committee, June 30, 1942, p. 17. Also Report of the Federal Crop Insurance Corporation, 1947, U.S.D.A., p. 7. See also Harold Halcrow "The Actuarial Structures for Crop Insurance," this *Journal*, Aug. 1949, Vol. 31, No. 3.

¹⁶ To conform with our goal, it should be worth exploring whether indemnities could be geared specifically to the "survival requirements" of individual farms.

¹⁷ Essentially this splitting of "total uncertainties" into a "budgeted partial risk" cost and an unbudgeted "residual uncertainty" cost is also implied in our unemployment insurance program where the compensation for a stated period of unemployment (e.g. six weeks or two months) is covered by premiums collected and where any "cost" of unemployment beyond that "insured" period is borne by the individuals and by society in some way through relief or public works. In this case, however, society's commitment to bear the cost of the "residual uncertainty" of unemployment is, at least in the U. S., not as explicit as in the case of crop insurance.

crop failure of one year. To carry larger reserves would in most cases prove economically unjustified. Within this limit, however, the returns from such individually accumulated reserves, especially of feed grains and forage, might be very substantial.

What might be an appropriate extent of a *centralized grain storage program*? Storage cost and rate of deterioration are probably substantially lower in terminal elevators than on the farm. As a specific measure for implementing our goal, an *emergency grain storage program* might be conceived that would permit farmers in poor years to *borrow grains up to their survival requirements* and to repay such loans *in kind* during good years with a modest interest charge. The price risk would thus be borne by the government, and the price-stabilizing effect of the storage program itself would reduce the cost of this risk to a minimum.

Cash and other liquid assets are not quite as "idle" as physical reserves as they can earn a small interest. They have no storage cost and do not "deteriorate." The increase in returns if they were invested by the farmer over the nominal interest they draw as liquid savings, however, should be charged against them. On the whole, liquid asset reserves as a safeguard against weather hazards are probably superior to grain or forage reserves kept for that purpose by individual farmers.

Drought Credit: In strictly economic terms, there is no reason why the saving should take place before the event of a poor period. In fact, the inexorable uncertainty of weather hazards speaks very strongly in favor of saving *after* rather than before. The type of credit should be one of "budgeted" or "supervised" loans, administered along the lines of FHA production loans, with local farmer committees advising the agency on applicants' eligibility, and with the borrower agreeing to budget his repayment schedule according to his ability to repay, in consultation with the lender. The agency should have ample power to exact repayment as soon as income rises above the critical survival limit. In all cases where repayment is delinquent on account of the borrower's negligence, incompetence or ill-will, the lender should have all the legal remedies for collection at his disposal.

Flexible Debt and Tax Payments: The foregoing three measures of crop insurance, reserves and drought credit are designed to compensate for income deficiencies below the survival limits caused chiefly by weather hazards. Such deficiencies can often be reduced

from the cost side, by adjusting traditionally fixed cost items to the income flow, to the farmers' ability to pay. The crucial cost items which lend themselves to such adjustments over time are debts and taxes.

The principal issue is how to apportion debt payments *over time* rather than bringing flexibility into the total amount of the debt obligation. I believe in using the full force of the law to safeguard the total amount of the lender's claim upon his debtor; but I am convinced that stability in the farm economy in high-risk areas requires the breaking of the time-rigidity of debt payments. Perhaps the most important type of measure would be a pattern of deferment privileges. The deferment should be granted subject to the borrower's agreement to budget his repayment schedule in consultation with the lender, as soon as his farm income rises above the survival limit. The same reasoning holds for making real estate taxes more flexible over time.

Diversification: Much is being made of diversification as a means of reducing price hazards in the Great Plains. Perhaps price variability of livestock products is significantly lower than that of grains. Undoubtedly, output variability in livestock enterprises is lower because of substitutability among feeds and greater managerial control over input-output ratios. Climatic and market conditions in the Plains place rather severe restrictions upon diversification. Lloyd Barber in his Kansas study found only slight differences in yield variability between the various crops, with wheat yields showing the lowest variability in most cases. Diversification within the crop system, therefore might not substantially reduce output variability due to weather hazards.

Opportunities for diversification in the Plains, however, do exist along two lines: (1) fuller use of non-crop land and land submarginal for crops in many years, say five or more out of ten, and (2) fuller use of under-employed family labor, especially during the winter season. Diversification that takes advantage of these two opportunities helps to prevent income from falling below the critical limit in three ways: by raising the level of income, by reducing the variability of total farm output, and by reducing price uncertainty.

Increasing Farm Size: Yield reduction due to crop hazards does not reduce appreciably the total cost of operating the farm. Operating costs, family living requirements, debt and tax payments stay practically the same whether the crop is good or poor. For this

reason, a larger farm is less vulnerable than a smaller one, within certain limits. A 50 percent reduction in net income means something very different to a farmer with a "normal" \$5,000 income than to one with a "normal" income of \$2,500. Hence, a fairly substantial level of "normal" output reduces the probability that a poor crop will press farm income down below the critical level of survival.

Price Supports: The specific significance of price supports to the high weather-risk areas of the Plains is two-fold: (1) price supports reduce the risk of poor crop years coinciding with ruinously low prices, and (2) grains are the dominant cash crop and have the highest price variability of any major farm product. The heavy dependence upon grains constitutes a serious price hazard which can be substantially reduced by effective price supports.

A long-range price support program that will prevent ruinously low crop returns, *but will not price the region's products out of their markets*, should be particularly helpful in stabilizing the Great Plains economy. A warning needs to be sounded, however, regarding production controls as a means for supporting prices. The danger that a drastic acreage reduction may coincide with a near crop failure is here much more serious than in low weather-risk areas.

There is a high premium for ingenuity, for finding new ways of doing things and for shaking off practices and institutional arrangements that were brought to the Plains from the humid east, and that do not fit the high weather-risk and arid characteristics of the Plains. Everytime a competent and honest farmer loses out in his fight against crop hazards, the region throws a challenge to the resourcefulness of farmers, community leaders, researchers and educators, to the wisdom of statesmen in our farm organizations, state legislatures and Congress. They all are called upon to make their contribution to the fullness and security of rural life in the Great Plains.

THE PROBLEM OF FARM BUSINESS SURVIVAL IN AREAS OF HIGHLY VARIABLE RAINFALL

DONALD C. HORTON AND E. LLOYD BARBER

Bureau of Agricultural Economics

RESEARCH on the problem of farm-business survival in areas of highly variable rainfall should be relevant in terms of yielding information on questions that have considerable long-time significance.

One such question concerns the conditions which cause some farm businesses to survive and others to fail in the same general economic environment. Is there evidence that the farm-firm which survives has been adapted successfully to areas characterized by extreme weather variability; or has survival been the result merely of historical accident or of the industry and good management of the farm operator? How one is to define "survival"—whether in terms of the continued existence of the farm business, in terms of some minimum degree of income stability or on some other basis—can be left to the discretion of the individual research worker.

A second question relates to the degree of stability farmers can afford. Can the farm business that takes adequate measures to safeguard itself against failure earn enough more in the long run to cover the added costs of this protection? In other words, is financial stability of the individual farm business feasible on a business basis in the face of extreme instability of yields and within the present competitive structure of agriculture in this area?¹

A third has to do with the personal distribution of heavy losses and heavy gains in high-risk agriculture. To what extent are the heavy losers and heavy gainers the same, and to what extent are they different groups of people? It is possible that returns from farming in high-risk agriculture over a period of years may average out as high as, or even higher than, those in other kinds of agriculture.

A final, but important, question concerns the attitudes that lie back of the competitive structure of farming in the area. To what

¹ Could a farmer who desires this degree of protection secure a larger net income as the operator of a more stable type of farm business in some other area, such as on a Wisconsin dairy farm, than he could earn on a farm characterized by highly variable crop yields? If so, the question arises as to what degree of protection is a reasonable goal for the farm operator under the present organization of farming in the area.

extent would the farmers of the area be willing to forego the opportunities for large gains in order to minimize the chances of disastrous losses? In theoretical terms, what is the nature of the "risk-preference function"? One aspect of this question is the extent to which the probability of losses is consciously anticipated by farmers who commit their resources to this area. Little, if any, empirical evidence is available with which to evaluate this question. In a sense, we are asking about the nature of the supply curve for entrepreneurship in high-risk agriculture.

These and similar questions help to identify needed fields of research, but they may not provide the most effective points at which to begin. It may be that we can learn something from the physical sciences about selection of specific projects. As in those fields the more effective research often may be that which superficially appears to be far removed from the central problem.

In the brief outline of specific fields of research which follows, two broad approaches are suggested. The first takes as given certain institutional arrangements, including public policies and the general competitive organization of farming. It then examines a number of possible lines of action that the individual farm business might take to safeguard itself against failure. The second takes as given an assumed pattern of farm business management and then inquires as to the costs and effects of public policies applied to entire areas.

Organization and Financial Management of the Farm Business

Research projects in this general field may be further divided into those with primary emphasis on the technical aspects of farming, and those that place primary emphasis on the financial aspects. What contribution to stability, and at what cost, may be expected from specific cultural and other strictly physical farm-management practices? This is largely a job of interpreting the results of physical science research in terms of costs and returns, with emphasis upon the contributions to stability of the farm business.

In this category falls research on the efficacy of physical reserves held by the farm business to increase stability of operations of the farm plant. To what extent can the stabilization of operations through the maintenance of feed and seed reserves be expected to give protection against financial breakdown of the farm business? It is conceivable that under certain conditions such farm-management policies might even lead to a greater degree of instability, as

when large physical reserves are held at the beginning of a period of falling farm prices.

Diversification of the enterprise and the provision of flexibility in the farm plant to allow a wide choice of alternatives are other stability measures of a primarily technical nature that require study. Within the rather narrow range of alternatives that exist in areas of high weather risk, do increased diversification and flexibility offer gains in stability that are at all commensurate with the costs?

In all of these problems, the characteristic uncertainty and variability of farm prices add to the difficulties of analysis. Prices are at once an important independent cause of instability and a factor which the research worker must include in his assumptions in studying the problems of weather risks. The widespread financial distress experienced in the Great Plains during the 1930's followed the occurrence of repeated crop failures in a period when farm prices were generally depressed. What the effect of such a series of poor crop years would have been in the absence of low farm prices presents a somewhat different question.

On the side of financial practices, we need to know more about the extent to which reserve and borrowing practices can contribute to greater financial stability of farm businesses. Holding liquid reserves in the form of cash and readily marketable securities may be viewed in part as the combination of a stable, low-yielding investment business with a relatively unstable farming business. The stable investment business is such that it can be liquidated or expanded with little inconvenience. Phrased in these terms, the question of the cost of such protection may be considered in terms of the returns that might be obtained by concentrating all of the capital in the farming business.

Whereas business-management practices as to financial reserves can be decided largely by the farm operator, the use of credit and the terms and conditions of borrowing depend also upon the lender. Unless a public lender is willing to take large risks as a matter of public policy, the contribution of credit to farm-business stability will be limited to the amounts loaned and the terms and conditions granted by lenders who are seeking to protect their own financial stability. Within these limits, however, lies a broad area of research as to the extent to which it is reasonable to attempt to use credit to supplement farm income in providing the funds to continue a

farming business in years of low income. Assuming that a farm operator has an assured line of credit, should he invest in farming assets and rely on credit to tide him over, or should he place more reliance on financial reserves in the form of low-yielding assets? The answer very likely may be that it depends. Even so, we should be able to determine upon what it depends in order to form a better idea of the respective limits of these related methods of accomplishing the same objective.

Of somewhat the same nature are research problems that relate to the use of insurance as a device for protection against catastrophic losses. The contribution of insurance, except that which may be provided on a cost-sharing basis by a public agency, depends upon the limits imposed by insuring agencies as well as upon the use the farmer makes of insurance. But within these limits are many questions relating to the extent to which stability can be promoted by agreeing to a schedule of fixed insurance charges as the price of protection against hazards which may be unrelated to the major forces that determine fluctuations in farm income. Here one of the problems is the extent to which protection against catastrophic losses is feasible without thereby building up fixed insurance charges that may accentuate financial difficulties in prolonged periods of low prices and yields. In this field fall also life insurance for the family as well as health, accident, and liability insurance. Here, as elsewhere in the consideration of methods of protection against failure of the farm business, the question often is one of how much protection is feasible under the present competitive organization of farming in this area.

In some respects equity investment by outsiders in the agriculture of the area is the converse of maintenance of liquid reserves by the operator. In the case of equity investment by outsiders, two separate businesses are combined in one operating farm. The farm operator conducts a farming business with leased assets and the outsider conducts an asset-owning business; whereas the owner-operator who maintains large financial reserves operates both a farming and a low-yield investment business. In the former, stability is achieved by placing a part of the uncertainty-bearing on an outsider. In the latter, greater stability is achieved by investing in high-grade, low-yielding assets.

This is not the place to speculate on the best techniques for studying these problems or to anticipate results that might be ob-

tained. The scarcity of usable data, however, will continue to tax the ingenuity of research workers. Most of the data now available are byproducts of some other process. Emphasis needs to be placed on the systematic development of statistical series for individual farms that will permit construction of the empirical models needed to study most of these problems. This means that existing data need to be studied for what can be gotten out of them, both as to substantive results and as to ideas for future collection of data. Building up a body of basic data and development of appropriate concepts and other tools of economic analysis are slow jobs at best. The sooner we get started at them the sooner will it be possible to do an effective job of reducing the area of controversy over appropriate farm business and financial management by a corresponding enlargement of the area of tested knowledge about the problem of farm-business survival in the high-risk agricultural areas.

In studying the types of problems outlined above, the research worker should be prepared for results which indicate rather narrow limits within which the individual farm can deal with the business-survival problem. Nevertheless, until we know more about these limits we are not very well prepared to say in what respects governmental or other group action is a superior method of handling the problem.

Governmental Action Affecting Entire Areas

We turn next to the second broad area of research which focuses on action of government in relation to entire geographical areas.

To do effective research, it is often necessary to hold constant for the time being certain phenomena that are not under study at the time. In a study of governmental and other group action to protect farms against failure, it may be most useful to assume that farm business and financial management is constant. One needs to assume also that there are limits to the costs the public is willing to incur to promote greater stability of farm businesses. With outside limits on costs, it is then possible to inquire regarding the specific costs and probable effects of a number of possible kinds of governmental action. Here again it is useful to distinguish between those activities of government that are designed mainly to influence technical aspects of farming and those that operate more at the financial level.

In studying the effects of alternative public policies in this field,

the research worker should take some liberties in assuming, for the sake of analysis, that legal and other institutional obstacles could be overcome if society really wished to follow particular lines of action. If the research worker restricts himself to his specialized job he should be free to study probable consequences of possible policies that seem at the time to be far removed from the realm of immediate adoption.

Hence, one area of research in governmental action relating to the technical aspects of agriculture might well be to determine the effects of specific regulations or inducements designed to direct high-risk agriculture into types of farming that are subject to less variation in yields. It would be instructive, for example, to assume that during the middle 1920's certain areas had been definitely zoned against crop-farming, and then follow through the next 25 years to determine probable net income both under this plan and under farming practices that have been actually followed. We might find resource allocation for the entire period has not been too badly out of line, but the personal distribution of gains and losses might be unsatisfactory.

A more tangible subject for study is the amount of stability for a given amount of cost to be expected from public expenditures on irrigation development. Considerable empirical data are available for such research. To what extent do higher fixed charges and greater vulnerability to small variations in prices replace greater variability in yields as potential causes of farm business failure when a shift is made from dry-land to irrigation farming? How much stability to entire communities, including adjacent dry-land farming, is given by irrigation farming? What does irrigation farming do to the distribution of uncertainty-bearing among farm operators, absentee landlords, and creditors; and is the resulting capital structure more or less vulnerable to variations in prices and costs than that characteristic of dry-land farming? Although it may require some ingenuity, the research worker may find that much of the basic data for such research is already available.

On the financial side, the research worker should also give considerable freedom to his imagination in the choice of projects. For example, what would be the fiscal cost and the distribution of benefits of a minimum net income guarantee to each farm family in a specified area? Similarly, what would be the fiscal cost and income effects of a government-sponsored crop insurance program in

which a specified part of the insurance premium was carried by the Government? What would be the net cost to the Government in the form of reduced income-tax collections of a plan whereby (1) the income-tax accounting period would be made long enough to average out years of high and low income, and (2) the farmer would be required to invest in government bonds in years of high income to obtain the advantages of tax reduction? Assuming that the public is willing to incur a given level of costs in one form or another to reduce the rate of farm business mortality in this sector of the economy, research studies of this type should provide a better basis on which to debate the relative merits of different programs involving similar cost to the Government.

The research areas so far discussed have emphasized direct stabilization of income. On the expense side there are also possible policies whose probable consequences need investigation. What, for example, would be the fiscal cost and probable effectiveness of a government-sponsored credit institution with power to finance specified fixed charges of both farmers and local governments in times of low farm income? The specified fixed charges presumably would include fixed operating costs of both farms and local governments when they are viewed as going concerns. Important in the consideration of effectiveness of such measures is the question of *which*, and what proportion of, farm businesses would be helped immediately by such a financing arrangement. Such a study would need to consider the prospect of losses on loans in evaluating probable public costs.

As emphasized at the outset of this paper, a real contribution can be made by research to the intelligent consideration of important public policy questions without attempting to give answers to questions that are political by their very nature. It is not serious if we spend time enlarging our knowledge of possible effects of actions that are never taken. Probably the transfer of basic knowledge from one area of investigation to another is large. There is even danger that we shall be so practical in our short-run choice of research projects that we may still be dealing with the depression of the 1930's when new problems arise.

DISCUSSION

HAROLD G. HALCROW
Montana State College

The Great Plains may be characterized—as has been done by Dr. Schickele—as a region within which good and bad crop years have occurred in bunches. In spite of this bunching, students of this weather and yield experience are almost unanimous in their conclusion that no definite pattern of length or sequence in weather cycles has been established. In one study based on tree-ring growth, covering 534 years, it was concluded to be impossible to work out any definite pattern of yield series. In another tree-ring study, covering 152 years, the conclusion was that cycles could not be picked out very successfully. In a study of wheat yields representing all the major wheat producing regions of the world it was concluded that chance presumably dominates fluctuations in yields from year to year in individual regions.

Thus, changes in weather from year-to-year usually have been regarded as random fluctuations and scepticism is general as to the existence of periodic cycles in meteorological data. This does not imply that the irregular fluctuations are entirely accidental or fortuitous, but for purposes of prediction the pattern and sequence of weather phenomena takes on the character of a random statistical probability. The bunching of good and bad crop years which has appeared so pronounced in the Plains in the last 20 or 30 years may be a random occurrence in the long range view of weather of the Plains. Uncertainty exists in respect to the weather for next year, for the next five years, or perhaps for the next 15 or 20 years but, on the basis of a priori judgment, a relatively accurate estimate may be made of the general level of weather conditions for the next 50 or 100 years. If this is the case, an empirical evaluation is possible in respect to this longer period of time; a statistical probability exists and the situation is insurable. On the basis of these data, however, the actuarial losses which would be encountered by an insurer should be estimated only in respect to this longer period of time.

For purposes of crop insurance, statistical probability cannot be determined with respect to the individual farmer's yield record in the Plains (1) because his yield record cannot be determined with the desirable degree of accuracy for an adequate period of time, and (2) because changes in a farmer's methods, practices, type of farming, etc., may make the yield probabilities significantly different from the yields existing in the past. Therefore, the type of all-risk crop insurance which has been in operation in the United States is unadapted to the Great Plains in an actuarial sense. Statistical probability may be determined on two other bases in the Plains: (1) long-run yield records for a crop area—such as a county, part of a county, or several counties—and (2) long-run weather records for an area.

In the case of area-yield insurance, a "normal" yield would be developed for each area. Premiums and indemnities would be based on yield probabilities for the area. A farmer in effect would insure a share of the crop in the

area and he would receive an indemnity whenever the area yield was below the level at which he had insured his "share."

In the case of weather-crop insurance, the long-run normal precipitation, humidity, temperature, etc. would be determined for a locality or area. A farmer could insure for a certain percentage of normal weather; i.e., he would receive an indemnity any time the weather in terms of the phenomena selected for the formula was below the standard insured

The relationship between problem, program, and research is a mutual one, as Horton and Barber have indicated. Research should be directed with the purpose to determine how or in what forms stability devices may be developed. Two processes must be undertaken. One is to think through the contribution which any device or program may make and the other is to assemble the data to determine how it may be adapted. In the case of crop insurance, for example, we should have a clear-cut outline of the purpose of insurance and a carefully reasoned statement as to the various forms which the program might take. Then the degree of income stability and the contribution toward efficient use of resources which can be made through use of insurance would be determined through inspection of models representing the various classes of situations. For this purpose we should obtain much greater detail than we now have on the internal construction of farm cases; especially on the individual yield patterns of farms within selected communities.

Likewise in the case of storage—the functions which storage may perform in the Great Plains should be identified and the type of program outlined which could best serve these functions. To what extent should storage be used toward stabilization of feed supplies and what types of storage facilities and instruments are best adapted? If our progress in attempting to answer questions such as these is disappointing, it may be because we have not thought of storage as a device which may be peculiarly adaptable to the livestock economy of the Plains and as a program which must be related to the yield variability of the Plains if the major function is to be performed.

The crucial question in this type of research is the concept the researcher has of the problem and the adaptation of the programs. The same set of basic data may be made to serve more than one purpose. For instance, the idea of expanding the feeding of wheat is currently under investigation in the Plains region. A pertinent question may be. In addition to data on costs and returns, how stable will be the farmer's supply of wheat? The answer to this is dependent both on the yield variability as well as on the storage program followed. The same data on yield variability may be basic to wheat feeding, storage, and crop insurance. Also yield data by farms over a period of years combined with information on prices and costs should be useful in determining what kind of credit policy a lender should follow.

In this type of yield uncertainty, without such stability devices the individual farmer finds it difficult if not impossible to budget inputs or to arrange the capital structure in a manner which will both maximize his net returns and carry him through a period of low income years. He is forced to compromise between the maximum gain and the minimum loss

and precise answers cannot be made to important questions of farm organization—involving diversification, feeding, storage, size of unit, type of farm, etc. Devices or programs designed to counteract some of the production uncertainty should allow greater precision in plans for farm organization and management. Consequently, much greater progress should be made in research fields dealing with farm organization and management in the Plains if programs counteracting some of the production uncertainty were successfully adapted.

The programs and the types of research are interrelated. The challenge involves (1) a type of research directed toward the development of programs which can contribute both to income stability and to the efficiency of resource utilization, and (2) a type of research directed toward the adaptation of farm units to the environment and to the types of programs which may be developed.

DISCUSSION

GLEN L. JOHNSON
University of Kentucky

In my opinion, three kinds of research require more emphasis than given to them in the Horton-Barber paper. The first of these is the need to further develop the theory of dynamic farm firms. A certain air of indefiniteness was present in the Horton-Barber paper about how to proceed in studying the roles of physical and financial flexibility and diversification. This indefiniteness indicates a need, on the part of our profession, for a more adequate theory of the firm. The need also showed up in Professor Schickele's paper where the theory available to him was only moderately productive of aids to the family farm. We might further localize this need by stating that a more adequate theory of the decision-making process is required.

Some exploration on my part convinces me that a combination of the statistical theory of sequential analysis with the theory used by Professor Schickele would yield realistic concepts of windfall profits, windfall losses, and more realistic concepts of returns to management, risk and uncertainty. Also, such a combination promises help in understanding the role of physical and financial flexibility in the making of decisions in noncertain situations. Such an understanding might suggest new managerial principles for use by firms facing high yield risks.

There are other possible lines of investigation which might improve the existing theory of the dynamic firm. For instance, Professor Schickele placed heavy emphasis on uncertainty concerning the length of runs of dry and wet years. Perhaps, the statistical techniques for handling probabilities of lengths of runs could be combined with the present theory of the dynamic firm to yield useful results. Might not such a combination help us understand the actions of a Plains farmer who says, "We've had 12 years of good weather in a row—I'm going to get ready for some dry years"?

It seems that most formal statistical techniques have informal counterparts in the decision-making processes of entrepreneurs. Currently, a rapid rate of progress in the field of statistical theory is offering us an unusual opportunity to work new techniques of statistical analysis into the theory of entrepreneurial decision-making.

Until we have a theory which adequately handles the thought processes of entrepreneurs, our understanding of our five to six million farm firms will remain poor. And, it will be especially poor for firms in high risk areas. Our current lack of understanding reduces the efficiency of our research—our empirical research gropes, only partially guided, and we are unable to predict the results of proposed public policies and institutional changes.

Our difficulty in predicting area wide results of public policies reminds us again that we have practically no theory for combining the effects of risk and uncertainty on the actions of individual firms into area wide effects. Both papers presented here today suffer from our profession's inability to supply a conceptual framework for going from the micro to the macro aspects of our *dynamic* economy. This is the second kind of research which requires more emphasis.

I turn now to a consideration of the third kind of needed research into the consequences of using alternative forms of farm production units more extensively. One reason for carefully appraising other kinds of production units as alternative ideals for the Great Plains is the fact that bad weather often adversely affects the welfare of families closely tied to the production unit. Professor Schickele has emphasized that the income level required for the family standard of living is part of the "critical limit of survival" for family-type farms. The question raised here is far from new—by implication, the universal appropriateness of the family farm was questioned in a report entitled, "The Place of the Family Farm in Our Land Tenure System." This report was prepared by Committee I of the Farm Tenure Conference held at Chicago in 1946. It would be appropriate for our profession to carry out an appraisal of the social and private implications of using other types of production units more extensively in high risk areas. For example, what would be the social and private consequences of large-scale corporation farming in areas of high wheat yield risks as compared with family farming? Another question might inquire as to the private and social consequences of more businesses which include both farm and nonfarm branches? Still another question could ask might not human suffering be less, human happiness greater and public costs lower if certain high risk areas were entered once each year for planting and again for harvesting in the years which produce worthwhile crops? These are examples of questions which might be profitably studied before finally settling on the family farm as the ideal production unit for high risk areas.

THE IMPORTANCE OF IRRIGATION IN THE ECONOMY OF THE WEST

H. E. SELBY

*Bureau of the Census*¹

I SHALL discuss the importance of irrigation in the economy of the West from two approaches: first, the extent of irrigation and some of its characteristics in relation to the economy; second, ways in which irrigation is of economic importance to certain groups of people.

By "the West" I shall refer to the 11 Western States, the states in which irrigation is of greatest importance. These states comprise more than a third of the land area of the country, and contain about 85 percent of the irrigated land.

The most recent statistics on irrigation for the West as a whole are somewhat old. In the 1945 Census of Agriculture, data were obtained on the number of irrigated farms and on the acreage irrigated.² For characteristics of irrigated land and data on irrigation enterprises, it is necessary to go back to the 1940 Censuses of Agriculture and Irrigation. Until we take the Seventeenth Decennial Census next year, however, these statistics will be all that we have except for areas where special studies have been made.

I

About one-half of the half-million farms in the West are irrigated in whole or in part. More than half the income of farmers is from irrigated crops and from livestock and livestock products obtained from irrigated crops and pastures.

According to the 1940 Census about 75 percent of the employed persons in all the extractive industries in the West—agriculture, forestry, fisheries, and mining—were employed in agriculture. Presumably about one-half of these, or 35 or 40 percent of the total employed in the extractive industries, were employed in irrigated farming. The proportion of workers in the nonextractive industries and occupations in the West who are supported indirectly by irrigated farming, doubtless is less than the proportion of workers in the extractive industries who are directly employed in it. This is

¹ Responsibility for the opinions and conclusions expressed is entirely the author's.

² *Farm Census Shows Substantial Increase in Irrigated Land*, U. S. Bureau of the Census, processed release, undated.

because some of the other industries—the Hollywood movie industry, for example—are geared to the entire national economy rather than to the economy of the West. It appears, however, that possibly as much as a third of the total population in the West depends on irrigated farming for its livelihood, directly or indirectly.

The irrigated area in the 11 Western States in 1944 was 17.3 million acres. In the remainder of the country only 3.2 million acres were irrigated, of which more than a third were in Texas.

Without irrigation, most of these 17 million acres would be barren desert or low value grazing land. With irrigation, it "blossoms like the rose" and produces crops that had a farm value of over two billion dollars in 1947 according to estimates of the United States Department of Agriculture.³ That was an average value of around \$150 per acre of irrigated cropland harvested, more than double the United States average for nonirrigated cropland harvested.

California has the largest irrigated area of any state, nearly five million acres in 1944, almost a fourth of the entire irrigated acreage in the country. Colorado is second, with 2.7 million acres; and Idaho third, with more than 2.0 million.

In a study of the longterm outlook for western agriculture, Clawson and Calhoun of the Bureau of Agricultural Economics estimated that 72 percent of the cash farm income from crops and 32 percent of the income from livestock and livestock products originated from irrigated land in 1939, and that irrigation produced 54 percent of the combined total income from crops and livestock.⁴ The more recent estimates of value of irrigated crops in 1947 by the United States Department of Agriculture are that 70 percent of the value of all crops in the Pacific Coast States was obtained from irrigated land and 60 percent in the Mountain States.⁵

Irrigation is responsible for the population of the West having more abundant, fresher, and lower priced supplies of fresh vegetables and fruits. Without irrigation much of these products would have to be imported from other parts of the country. Without irrigation practically all dairying in the West would be devoted to

³ *Irrigation Agriculture in the West*, U. S. Department of Agriculture, Miscellaneous Publication No. 670, November 1948, page 3.

⁵ *Op. cit.*, *Irrigation Agriculture in the West*, page 3.

market milk production and most other dairy products would have to be imported.

Irrigation bears an important relation to the western livestock industry. More than two-thirds of the entire irrigated acreage is used for producing feed crops and pasture. Dairying is the principal type of livestock production on the irrigated lands, but a large part of the irrigated crops and pasture is used for beef cattle and sheep production. Nearly three-fourths of the total land area in the West is range land, used chiefly for grazing beef cattle and sheep. The West has always produced an important surplus of beef cattle and sheep to supply the needs of the rest of the country. For the past three decades, however, production of range livestock has been declining, as a result of declining productivity of the range.⁶ Increasing production of irrigated feed crops and pastures has offset this declining range production to a considerable extent.

Irrigated feed production also makes possible the fattening and finishing of more beef cattle and sheep in the West to supply the expanding western markets. In the early days most of the range cattle and sheep were shipped east to the cornbelt for feeding. As the population of the West increases, more feeding is needed in the West, which would be impossible without the feed crops produced by irrigation.

The net result of new irrigation development is chiefly more beef cattle and sheep production than would have occurred without the irrigation development. This probably sounds like heresy to some persons, because most new irrigation development is based on anticipated production of fruit, vegetables and other cash crops, and dairying. The point is, that there is already a large acreage of irrigated land in the West now used for feed crops that is suitable for producing fruits, vegetables, and other cash crops, and that can and will be used for such crops as rapidly as the market warrants. Also, whenever the western market for dairy products warrants, use of irrigated feed crops and pasture can and will be shifted from beef cattle and sheep feeding to dairying. With new irrigation development, needed increase in production of the more intensive commodities may occur in the new area instead of in some area where it otherwise would have occurred, or production in the new

⁶ H. E. Selby and Donald T. Griffith, *Livestock Production in Relation to Land Use and Irrigation in the Eleven Western States*, B.A.E. Berkeley, Calif., March 1946, processed, p. 8.

area may even displace production in an older area. But the net result of the new irrigation development is largely more beef cattle and sheep produced in the West than would have been produced without it.

It should be noted, however, that the result of new irrigation development in a local area may be less, rather than more, livestock feed in that particular area. The reason for this is that the additional water supply may make it more profitable to raise sugar beets, beans, or other cash crops on land that was used to produce hay when the water supply was less adequate. Such displacement of feed production by cash crops in a certain area, however, tends to postpone similar displacement that otherwise would occur in some other area.

A most important aspect of irrigation is its stabilizing effect not only in the agricultural economy, but in the entire economy of the West. Irrigated farming is much less subject to hazards of weather than nonirrigated farming. Widespread drouth and resultant failure of nonirrigated crops is therefore not so great a hazard to the total economy as it would be if there were no irrigation. By diversifying farm production irrigation makes the region less subject to business depression.

Irrigation is only one phase of the control and use of water resources in the West. Other important phases are flood control and use for hydroelectric power, navigation, domestic water, and recreation. Most of the larger irrigation developments are multiple-purpose projects, combining irrigation and one or more of the other purposes of water control and development. In many of these projects no single purpose would justify the development, but by combining the several benefits the project becomes feasible. Thus irrigation is a factor in obtaining more complete utilization of water resources, and this in turn makes possible more complete utilization of other resources.

But now, although irrigation provides the means by which a considerable proportion of the population in the West makes its living, does that mean that those people are any better off as a consequence of irrigation? Perhaps they could make just as good as or better livings elsewhere. Who benefits from irrigation? Is anyone worse off as a consequence of irrigation? This brings me to the second part of my discussion, on ways in which irrigation is of economic importance to certain groups of people.

II

I shall discuss very briefly some of the ways in which it seems to me that irrigation is of importance to six groups of people, and then comment on its significance to the general public.

1. *Settlers on irrigation projects.*

Probably most people think of the settlers on irrigation projects as the principal beneficiaries of irrigation. In most cases, however, the amount the settler has to pay for his farm, or for his farm and irrigation construction cost combined, is as much or more than its full economic value for farming. Usually he pays about as much as he would have to pay for a nonirrigated farm of comparable productive capacity. Even on Federal projects subsidized by interest-free money, it is questionable whether the settler gets much benefit from the subsidy, for he is required to pay "all the traffic will bear." A statement sometimes heard in the West is that it takes three crops of settlers to make an irrigation project succeed, and that has been almost the case on some projects.

A fundamental principle of Federal Reclamation policy however, ever since the passage of the original Reclamation Act in 1902, has been to provide family size farms for settlers. The policy also is to give preference to families who have no other means of earning a livelihood, or who have been compelled to abandon other farms through no fault of their own. Doubtless these policies have provided opportunities for farm ownership to many settlers whose only alternatives for employment were as farm tenants or laborers. Many other irrigation farmers have developed their own irrigation facilities through individual or cooperative effort and thus have provided themselves with successful farms and homes, and sometimes they have obtained substantial financial returns. Certainly the early Mormon pioneers in the West owed their settlement possibilities to irrigation. But whether most settlers, on all irrigated lands, have been provided better opportunities by irrigation than they could have found elsewhere, is at least questionable.

2. *Owners of land when it becomes irrigated.*

For this group of people the result of irrigation development varies from large financial gains to large losses. When land is irrigated it enhances considerably in value as a result of its increased

productivity. In some cases, the enhancement in land value considerably exceeds the cost of the development, and represents a substantial financial gain to the landowner. In other cases, the cost of irrigation development exceeds the enhancement in value, and the landowners may lose money, or may default on their payment of the irrigation cost and thus pass on part of the loss to the financiers of the development.

With government development of irrigation one of the problems is to prevent speculative increase in the value of the land to be irrigated from absorbing the ability of the land to pay for the irrigation development. By means of antispeculation laws and regulations, owners of land to be irrigated can be restricted reasonably well from selling the land for more than its appraised value without irrigation. But the ability of the land to pay for the irrigation development often gets capitalized into land value through farm mortgage borrowing. The settlers are able to incur so much mortgage debt that it becomes impossible for them to keep up both their mortgage and their irrigation payments. When that situation becomes general throughout a project, it is usually the irrigation payments that are compromised, even though they may be the prior lien on the land, because public opinion would be too unfavorable toward mass foreclosure of the lands for the irrigation payments.

3. Investors in irrigation development.

In some cases the owners of land to be irrigated are able to finance the cost of the irrigation development themselves, but more often borrowed capital is required. Many individual investors have lost money on unsound irrigation development. Many bonds of irrigation enterprises have sold for a few cents on the dollar, or have become worthless. In a recent study made by the Bureau of Agricultural Economics and the Soil Conservation Service, but not yet published, of about 50 selected irrigation enterprises throughout the West, it was found that the financiers of more than a third of the enterprises had lost substantial proportions of their invested capital.

The reason why irrigation enterprises fail financially is almost always that the cost of the development exceeds the value of the increased productivity of the land; that the ability of the land to pay for the development is capitalized into land value before the cost is paid; or, in most cases, a combination of these circumstances.

Financial failure often is ascribed to poor land or to an insufficient water supply. The fundamental cause, however, is the cost of the development relative to the benefits. Relatively poor land can pay for irrigation, and practically any kind of water supply warrants development, if the development cost is low enough.

Financial failure seldom results in abandonment or discontinuance of an irrigation enterprise. Whatever amount the settlers can pay is better than nothing for the creditors. The settlers on the project usually can pay as much or more than could be realized by dispossessing them and getting new settlers. After the financiers of the enterprise take their loss and reduce the debt down to the ability of the settlers to pay, the project becomes a "successful" one.

4. People in industries and occupations that serve irrigated farming.

This group is comprised of the people who transport, market and manufacture the products of irrigated farming and those who supply goods and services to the people engaged in irrigated farming. Irrigation development creates opportunities for employment in the vicinity of the development. It creates need for various specialized occupations such as irrigation engineers, builders of irrigation works, manufacturers of irrigation equipment, water right lawyers, public officials who supervise use of water, and even for college professors who teach irrigation, and agricultural economists who study the economic problems of irrigation.

Where the development is in an entirely new area, entirely new opportunities in the service occupations are created. If the area is partly developed and settled at the time of the new irrigation development, increased volume of business is provided for service occupations already there. The person already engaged in the service occupations may or may not benefit from the increased business. If only one railroad serves the area, it is rather sure to receive an increase in its volume of business. But in some lines of business the new development may attract so many competitors to the area that the volume of business available to the existing firms decreases.

5. Owners of land in villages and towns in irrigated areas.

The need for service industries and occupations in connection with irrigation development causes the villages and towns in the

area to grow and the land to increase in value for both business and residential purposes. As a part of the planning for the Bureau of Reclamation's Central Valley Project in California a study was made of relationships over a period of years between the assessed value of farm real estate and that of nonfarm real estate. The study covered the Central Valley and also the Imperial Valley, both predominantly irrigated farming areas. In both areas it was found that for a given amount of increase in the total value of farm real estate, an increase of about 25 percent as much occurred in the total value of nonfarm real estate.⁷

In a few cases a nominal tax has been assessed on nonfarm land in an irrigated area to help pay the cost of the irrigation development. On the whole, though, the owners of such land have received such enhancement in value as a gift. It is quite probable that their gains from increment in land value, in the aggregate, have been greater than the gains from increment in value of the irrigated land over and above the costs of the irrigation development. It is no wonder that chambers of commerce promote irrigation development in their vicinities.

6. People who would have been better off without irrigation.

As the population of the country increases, more food is needed. Irrigation development increases the acreage of land suitable for crop production. This is one way of getting an increased supply of food, but is by no means the only way. The acreage of land suitable for crop production also can be increased by land clearing, drainage, and soil conservation measures; the production of food on presently available cropland can be increased by more intensive farming; and additional food can be imported. If any particular irrigation development had not occurred, most of the increase in food supply that it provides would have been obtained through development of additional land by other means, or else by more intensive production on existing land. Instead of the opportunities for employment provided by irrigation development, opportunities for employment would have been provided by the increased food production elsewhere.

Increases in value of farm land, in volume of business of service

⁷ Cf. my article *Indirect Benefits from Irrigation Development*, *Journal of Land and Public Utility Economics*, February 1944, p. 50.

industries, and in value of land in villages and towns, more or less comparable to those that occurred in the irrigated area, would have occurred elsewhere. More or less comparable financial gains to those realized from the irrigation development would have accrued to different persons, who were prevented from receiving them by the irrigation development.

Without the irrigation development, the increased farm production and its corollary economic effects might occur in some other part of the country, some other part of the West, some other part of the same state, or even in the same county; or it might occur as a very slight increase diffused throughout many farming areas. If there were no irrigation in the West, the nonirrigated farm land in the West Coast valleys certainly would be at a premium for production of fruits, vegetables, and market milk to supply western markets, and its value would be much higher than it is.

The history of most irrigated areas shows a rather constant increase in intensity of farming—more fruits, vegetables, and other cash crops, or more dairying. This is the result of expanding market demand for these commodities. As more of these higher value commodities are produced, the value of the land increases, because intensity of farming, or value of crops per acre, is the most important determinant of value of irrigated land.⁸ New development of irrigated land may prevent or postpone opportunity for present irrigation farmers to grow more profitable crops and benefit by resultant increase in value of their land.

Increasing farm production by means of new irrigation in periods of surplus crop production increases the quantity of surplus production, and that further depresses farm prices. Even though the crops produced on the new land are not those in surplus supply, they tend to prevent possibilities of diverting land in other areas from use for surplus crops to use for nonsurplus crops. Particularly in times of surplus production, therefore, farmers in other parts of the country look askance at government development of irrigation in the West. There is considerable time lag, however, between the construction of most irrigation projects and the bringing of the land into production. If irrigation construction could be maximized in periods of depression and minimized in periods of prosperity, it not only would bolster employment in the depression periods but also

⁸ Cf. my article *Factors Affecting Value of Land and Water in Irrigated Areas*, *Journal of Land and Public Utility Economics*, Aug. 1945, p. 253.

would tend to bring in the additional production during the following periods of prosperity when it is needed.

Lastly, we come to consideration of the general public and ways in which irrigation in the West is of economic importance to it. The Federal government is spending a few million dollars a year to subsidize irrigation development through the device of interest-free money. What does the general public get for that expenditure?

As population increases, if additional farm land is not developed the additional food that is needed can be obtained by more intensive farming of present farm land. To obtain the additional production in this way, higher prices for food are necessary to cover the additional inputs of labor, machinery, and fertilizer. The higher prices will apply not only to the additional production, but to the total production of food. But if the additional production of food is obtained by development of additional land, and if the development cost is not too great, the increased production may be obtained at the same costs as present production.

Preventing only a very slight increase in food prices could very easily justify the expenditure of many millions of dollars by the general public for irrigation development. So far as I know, no way has been devised for measuring the relationship between irrigation development and food prices. If my theory is valid that the net result of new irrigation development is chiefly production of beef cattle and sheep, a method of evaluating subsidy of irrigation in terms of prevented rise in cost of food perhaps lies in the relationships of supply and demand to prices of beef cattle and sheep.

Obtaining increased food production by means of irrigation development rather than by more intensive production on existing farm land has the important additional advantage that it increases the total area of cropland and thus adds to the natural resources of the country. This advantage also is difficult to evaluate—in time of war the additional resource may be invaluable.

FEDERAL AID TO IRRIGATION DEVELOPMENT

WALTER U. FUHRMAN*

Bureau of Agricultural Economics

THE development of irrigation is a part of the history of agriculture. Modern irrigation in the United States began slightly more than 100 years ago—nearly two decades before enactment of the first homestead law. It was an adjustment to the arid conditions of the West in the face of urgent need for food for an increasing population and winter feeds for expanding livestock industries.

As with other lines of agricultural development, early irrigation was undertaken without benefit of direct Federal aid. Many small irrigation systems were built by individuals or by small partnerships. Conditions in many places, however, required action by larger groups so settlers organized into cooperative or mutual water-ditch companies for constructing and operating irrigation systems. Understandings regarding "water rights" for irrigation purposes became established by usage and over a period of years gradually became formalized into law by statutory enactments and court decisions. Early irrigation associations often based on informal agreements have also been formalized under various state laws into mutual or cooperative irrigation companies, associations, or irrigation districts.

Projects that required simple low-cost construction were sought. The better, more easily developed lands near dependable and readily accessible water supplies were selected for development. As the more favorable sites were occupied, project development became increasingly more difficult and costly. Storage dams, pumping plants, and long canals over difficult terrain increased the cost of later irrigation developments. To assist in financing and operating such irrigation projects, all of the 17 western states have passed irrigation district laws. These differ in detail but irrigation districts set up under state law generally are public or quasi-public corporations having authority to levy assessments against all lands within their boundaries that benefit from district facilities. These districts have proved very useful, particularly in taking over and operating systems built by the Federal Government. However, they have not

* The writer acknowledges with thanks many helpful suggestions received from members of the staff of the Bureau of Reclamation in Washington, D. C., and Boise, Idaho.

commanded financial resources sufficient to construct the more costly projects. A few states, cities, and commercial companies have assisted in irrigation development, but these give little promise of major future contributions except that receipts from water furnished to cities and industries from multiple purpose projects may contribute substantially to payment of construction costs of some projects.

As the nineteenth century drew to a close it became apparent that Federal funds were needed to finance irrigation development if reasonably full utilization of western water resources was to be achieved. As early as 1888, funds were appropriated for the purpose of investigating the extent to which arid regions could be redeemed by irrigation. Two years later an Act provided that patents issued for lands west of the one-hundredth meridian contain right-of-way reservations for ditches or canals constructed by authority of the United States. In 1902 the Federal Government, by passage of the Reclamation Act, entered the field of direct promotion of irrigation. There were then around eight million acres of land under irrigation. By 1945 Federal and private developments had increased this to approximately $19\frac{1}{2}$ million acres. In 1945 Federal works were capable of furnishing water to more than 5,000,000 acres. Slightly over 2,437,000 acres could be furnished a full supply of water from Federal facilities; 521,000 could be furnished a supplemental supply of storage water; and 2,055,000 could be furnished a full or supplemental supply under special contracts. At present, roughly one third of the irrigated acreage is served by individual and partnership enterprises and a third by mutual or cooperative companies. Some 76 percent of the irrigated land in the 17 western states is served by works constructed by private interests, and 13 percent from works constructed by the Federal Government. The remaining 11 percent is served by both Federal and private works.¹

From 1945 to 1948 acreage served by the Federal projects increased approximately nine percent. Future development of large irrigation projects is likely to be mainly in the hands of the Federal Government, although significant acreages may yet be brought under irrigation by individual enterprises through pumping from farm wells or neighboring streams and ponds and by construction of small farm reservoirs.

¹ *Irrigation Agriculture in the West*. U.S.D.A. Misc. Publication No. 670.

When the Reclamation Act was passed in 1902, it apparently was expected that with modest financial assistance from the Federal Government, reclamation would pay its own way. According to a Fact Finders Committee, appointed by Secretary of the Interior Hubert Work in 1923 to make a comprehensive review and appraisal of the first two decades of Federal reclamation experience, it was initially contemplated that money used by the Reclamation Service for reclaiming arid and semi-arid lands by irrigation should not be raised by taxation. Construction funds were to be derived from the sale of public lands in the states to be benefited, to which were added later such moneys as are derived from royalties from oil and potash lands.² Receipts from extractive resource-depleting industries were thus to provide funds for the construction of relatively permanent continuous-income-producing irrigation works. It was intended that this fund should not be lost but should be held in trust as a revolving fund, and reinvested in the reclamation of arid land as fast as paid back.

The Reclamation Fund, however, proved to be inadequate. Net construction cost of projects subject to repayment, as of June 30, 1923 already was, in round numbers, \$143,000,000. This large construction program had exhausted the Reclamation Fund and made necessary a loan of \$20,000,000 to keep the work moving. Such loans also proved inadequate. Direct appropriations have provided most of the construction funds of the Bureau of Reclamation. Total accretions to the Reclamation Fund, as of June 30, 1948 were approximately \$250,000,000, whereas total allotments and appropriations for reclamation purposes had reached a total of around \$1,530,000,000.³ Appropriations for construction purposes to the Bureau of Reclamation for fiscal 1949 were around \$240,000,000. A Bureau of Reclamation program calls for expenditures of \$3,891,900,000 during the 7-year period beginning with fiscal 1948.⁴

With respect to repayment of irrigation costs Congress has steadfastly maintained its original position that costs assigned to irrigation works, including investigation and engineering, should be repaid to the United States. It has, however, liberalized its re-

payment requirements, and increased its legislative safeguards to sound development in several important respects. Terms of payment have become more and more lenient, the sources from which payment can be drawn have been broadened, more thorough investigations have been stipulated, the advantages of multiple purpose projects have been recognized and the allocation of joint costs to their several purposes has been authorized.

With regard to payments, the Act of 1902 authorized the Secretary of the Interior to determine the charges per acre of land with a view to returning to the reclamation fund, in not to exceed 10 annual installments and without interest, the estimated cost of constructing the project.⁵

Before many years, however, a considerable number of projects had failed to meet the schedule of construction charges set up under the 1902 Act. In 1914 all accrued charges were placed in the construction fund and a new start was made under a 20-year repayment plan.⁶ Extension of the repayment period helped, but did not solve the delinquency problem. A few years after the close of World War I many contracts were again seriously in arrears. Congress then provided that all construction charges should be payable in annual installments based on the productive power of the land. The period of payment under this plan was indefinite but originally it was expected to run not more than 40 years. Determination of gross value of crops led to disputes and administrative difficulties, and provision for such contracts was repealed in 1926, but twenty of the irrigation districts which entered into this type of contract with the United States were still paying on this basis in 1947. The Act of 1926 authorized the Secretary of the Interior, upon request of individual waterusers or districts,⁷ to amend any existing water-right contract so as to increase the period for repayment of construction charges not to exceed 40 years from the date of the first payment under the original contract and also to make new contracts with up to 40-year repayment periods.⁸ The 40-year repay-

⁵ The Reclamation Act, Section 4.

⁶ Reclamation Extension Act, Section 2.

⁷ Contracts for payment of irrigation construction charges during the early period were made with individual land owners and homesteaders. Such contracts are still in force on a few projects, but by the Act of May 15, 1922, contracts with regularly organized irrigation districts were authorized. Since then contracts with organized irrigation districts rather than with individual landowners have become the general practice.

⁸ Sections 45 and 46 Omnibus Adjustment Act, 1926.

ment period is still in force but repayment has been modified in other ways which in effect lengthen the repayment period.

The Reclamation Act of 1939 provides for a development period of not to exceed 10 years before the beginning of the 40-year repayment period, thus extending the period of interest-free money to 50 years.⁹ Moratoria granted under special acts during depressions have increased the average contract life by approximately 10 years, according to a recent report by the Bureau of Reclamation.¹⁰

The Reclamation Act of 1939 also permits construction costs to be separated into two parts; (1) those incurred to provide facilities for furnishing the water supply—the main dams, reservoirs, pumping plants and carriage canals; and (2) those incurred for the water distribution system—secondary canals and laterals. Costs of the distribution system are to be paid for under the regular 40-year plan after a development period of not more than 10 years. With regard to water supply features, the Act authorizes water rental contracts with charges sufficient to cover annual operation and maintenance costs of the water supply works, plus a payment on construction costs to be determined by the Secretary of the Interior. These contracts may be short or long, but they may not exceed 40 years. At the expiration date new contracts presumably would be negotiated. Water users or irrigation districts establish no definite water rights under water rental contracts, whereas under repayment contracts permanent water rights are established.

Long repayment periods have been criticized on the grounds that they prevent farmers from accumulating equities in their farms. If construction payments drained off the total surplus above current operating and living expenses, this would be true. The Government, however, has demonstrated neither the ability nor the desire to do this. In determining the waterusers' ability to pay under re-

⁹ Section 7(b) Reclamation Project Act, 1939.

¹⁰ *How Reclamation Pays*, U. S. Dept. of Interior, Bur. of Reclamation, 1947. This publication reports that at the end of 1946 the repayment periods for 66 projects or major divisions of projects involving 177 contracts were distributed as follows.

Number of projects or major divisions	Repayment period (Years)
15	26-39
26	40-49
12	50-64
6	65-79
4	80-99
3	100-150

negotiated contracts, a reasonable return on investment, including normal land values, is included in current operating expenses. This provides a source of savings or capital accumulations for the owner-operator. It is not uncommon for land values to be maintained on projects which are in arrears on the payment of construction charges. Delinquency on water charges, therefore, is by no means conclusive proof of financial distress on the part of the water-users.

Delinquencies on construction charges are not large. The total due to June 30, 1948, was \$84,659,231.71, of which only \$2,369,020.66 (three percent) was unpaid. Delinquencies are kept relatively low, in part, through renegotiation of contracts with projects which are in arrears. Amendatory contracts are being made for projects which now have substantial uncollected items. One aspect of present negotiations is the reduction of annual installments through extension of the repayment period without reduction in the total obligation to be paid.¹¹ The usual reason given for default in payment is that the annual charges are in excess of the district's ability to pay. However, in some cases, there probably is an appreciable element of unwillingness as well as inability to pay. Undesirable features of contracts also may have contributed to delinquency. Virtually all of the earlier contracts provided for fixed annual payments without regard to fluctuation in economic conditions or to changes in the waterusers' ability to pay. Some projects were assessed on substantially more acres than were irrigated, others were authorized under 40-year repayment law with the informal understanding that the ability to repay in 40 years should be thoroughly reviewed before construction payments started.

Contracts are now renegotiated on the basis of detailed investigations by the Bureau of Reclamation regarding the district's ability to pay both operation and maintenance costs and construction charges under expected future average conditions. These contracts usually contain some formulae for adjusting the annual installment

¹¹ An exception is a recent contract on the Tucumcari project which writes off construction charges in excess of the estimated amount that can be collected over a 40-year period. Congress also has written off all the construction charges for five small reclamation projects (approximately \$3,325,000). Four of these were started in the early years in advance of adequate investigations and under pressure. Somewhat more than \$14,000,000 has been written off other projects primarily because of reclassification of land and the suspension of the poorer lands from paying status. Although some adjustments stemmed from the depression of the thirties which also caused substantial adjustments in other kinds of agricultural debts.

on construction charges in accordance with changes which may occur in farmers' dollar income and in the purchasing power of this income. Increased attention also has been given to the effect of differences in soils, topography, climate, markets, and other factors on the waterusers' ability to pay construction charges. Some recent contracts, such as those with the Columbia Basin Districts, allow for full recognition of these factors. These contracts specify differential construction payments. During the 10-year development period, water rental charges in Columbia Basin are to be graduated in accordance with the estimated productivity of various grades of land to produce net income under average management.

The desirability of adequate investigation prior to construction of projects was emphasized by the Fact Finders who stated that "success can come to future Federal Reclamation ventures only if projects are authorized upon a thoroughly scientific consideration of the probable power of the project to enable the farmer to repay construction costs and to win a living from irrigated lands. Community and political demand to secure projects," they said, "should be considered only after full knowledge of the feasibility of a proposed project has been secured."

Congress, in 1924, declared that no new project or new division of a project shall be approved for construction until detailed information is secured concerning the water supply, the engineering features, the cost of construction, land prices, and the probable cost of development, and until a finding is made in writing that it is feasible, that it is adaptable for actual settlement and farm homes, and that it will probably return the cost thereof to the United States.¹²

A showing of feasibility and of probable return of costs to the United States had become increasingly more difficult: (1) because new developments have had to turn to more difficult and costly projects as the lower cost and more advantageously located sites became utilized; (2) because great and disproportionate increases in construction and development costs have occurred; (3) because thorough investigation itself costs something but especially because such investigations by close examination often disclose additional obstacles to be overcome which involve increased costs. Detailed land classification, for example, usually eliminates some land which would be classed as irrigable in a reconnaissance survey.

¹² Subsection B, Section 4, Second Deficiency Act, 1924 (Fact Finders' Act).

In supporting their recommendations for sound policies and full investigation before approval of projects, the Fact Finders noted that in many cases the cost of works built by the Government was more than \$100 per acre. They quoted the testimony of the Chief Engineer of the Bureau of Reclamation to the effect that he knew of no new project where water could be provided at less than \$100 an acre. They also observed, as has often been done since, that "construction costs are in almost every instance larger, in some cases several times larger, than original estimates."

On the Columbia Basin Project the present estimated construction cost of irrigation works, including irrigation's share of the Grand Coulee Dam and reservoir is approximately \$410 per acre of irrigable land.¹³ Very preliminary estimates for the Missouri River Basin Project indicate an average cost of around \$400 per acre for the project as a whole. Cost varies widely among units of the project. For California's Central Valley, approximately \$253,000,-000 of construction costs are allocated to irrigation. The project, as presently authorized, will provide a full water supply to 542,000 acres and a supplemental supply to 510,000 acres. Assuming supplemental water supply at half of the full supply, this would be equivalent to a full water supply for approximately 800,000 acres at a cost of around \$300 per acre.

Water users generally are reluctant to obligate themselves to repay such high costs even though payment is over long periods and without interest. Often it would not be to their economic advantage. Ways of relieving waterusers from the full burden of construction costs have been sought in various directions. Four states—Colorado, New Mexico, Nebraska and North Dakota—have legislation providing for organization of Conservancy Districts authorized to levy and collect property taxes. Levies are made in proportion to the estimated benefits accruing to the property from irrigation developments. The most fruitful means of lowering waterusers' obligations thus far devised, however, is to use power revenues to help pay for irrigation works.

The law requires rates for Federal power to be at least sufficient to cover current operating expenses, plus not less than three percent annual interest on the unretired investment in power facilities, plus such fixed charges as the Secretary of the Interior deems

¹³ On the assumption that 1,029,000 acres will eventually be brought under irrigation, and exclusive of irrigation's portion of \$191,000,000 unallocated costs.

proper. It is the policy of the Department to set these fixed charges so that power construction costs will be returned in not less than 50 years. The interest component on the power construction costs is applied to help retire the cost of irrigation works on a number of projects. If prospective rates and sales of power are such that revenues will be more than sufficient to pay operating costs and interest, and to retire construction costs in 50 years, the surplus revenue from power may be applied to repayment of irrigation costs.

On the Columbia Basin Project, for example, it is estimated that at two mills per kilowatt hour, power revenues will result in large surplus revenues that are to be used to retire irrigation construction costs. The \$410 irrigation cost per acre is expected to be retired roughly as follows: interest component on construction costs, 20 percent; surplus power revenue, 60 percent; and water users, 20 percent. The portion of irrigation construction cost which is to be repaid by water users on the Central Valley Project is around 22 percent—on the Missouri River Basin Project around 23.

The use of power revenues to retire part of the irrigation construction costs has been authorized only for individual projects which have both power and irrigation features. These include some very large projects. There are, however, potential irrigation projects on which no opportunities for surplus revenue-producing power facilities occur. The Columbia River Basin Project report states that many irrigation projects awaiting development in the Basin have no opportunities for power production directly associated with them. Without the assistance of power revenues the report finds that these irrigation projects cannot pay the reimbursable costs. By contrast, however, potential main-stem power development will have repayment capacities far above their reimbursable costs. The report argues for authorization to pool surplus power revenues to help pay irrigation costs on any irrigation project or feature where needed in the entire Columbia River Valley. This authority would appreciably increase the number of irrigation projects which could meet feasibility and repayment requirements because large power revenues would be available to cover high-cost irrigation works.

Substantial aid to findings of feasibility and repayment of reimbursable costs has been achieved by Congressional broadening of nonreimbursable benefits from multiple purpose projects. Present

national policy is to require that construction costs allocated to irrigation, municipal, and industrial water and to power be repaid, whereas costs allocated to flood control, navigation, and fish and wildlife conservation are not. By national policy these latter items are recognized as "public benefits" and therefore are nonreimbursable, although a fully satisfactory explanation as to why benefits from keeping excess water off a river bottom farm are public benefits and therefore wholly nonreimbursable, whereas the benefits from taking surplus water to an arid bench farm are private benefits and therefore wholly reimbursable, has never been brought to my attention.

Bills are now before Congress which, if passed, will recognize additional purposes as nonreimbursable items under multiple-purpose projects. These include salinity control, sediment control, recreation, improvement of public transportation, and promotion of national defense. It is proposed that these measures be adopted not only to improve the feasibility and repayment prospects of projects not yet authorized, but also to reduce the repayment burden on water users and power revenues on projects already built or now under construction.

That the water user is not the sole recipient of benefits from irrigation development is receiving ever wider recognition. Persons engaged in servicing, processing, merchandising, transportation industries, and other pursuits within the immediate area and also in other parts of the country frequently are directly benefited. Various indirect benefits are nation-wide. Methods by which direct payments on irrigation costs might be obtained from beneficiaries other than water users have been sought without great success. Conservancy districts have helped to a limited extent. Power users may contribute indirectly if the use of power revenues to pay irrigation construction costs results in higher power rates than otherwise would have been charged. Present efforts to spread costs widely and thus lighten the allocation to irrigation are in the direction of placing a larger portion of costs in nonreimbursable categories. The legislative trend appears to be heading in the direction: (1) of using power revenues to repay costs of irrigation works; (2) reducing construction costs allocated to irrigation or placing them in the nonreimbursable class and (3) of finding irrigation feasible if there is reasonable assurance that farmers on the least productive irrigable lands will be able to pay average operat-

ing and maintenance expenses, once the irrigation works are constructed.

How much Federal subsidy should go into the building of irrigation works? A sound appraisal of this problem becomes increasingly urgent with mounting construction cost per acre of irrigable land as more difficult projects are undertaken, with relatively lower net benefits per acre as irrigation is extended to less promising localities, and with reduction in the proportion of the cost to be repaid by waterusers. The insistence of local pressure groups for project construction increases as payment allocations to local groups diminish.

The question of how much public investment should go into irrigation works does not lend itself to a direct or simple answer. Its answer is related to those of numerous other questions concerning national policy. How much of the national income should be spent by the Federal Government? How much of this should be used for the conservation and development of resources? How do prospective returns or contributions to national well-being from investment in irrigation works compare with those from investment in other lines—in development of metals, ores and minerals, in power facilities, roads, research, education, health, and wildlife conservation? Public and private benefits flow from all of these programs. All may be proper functions of Government, but all cannot be supported to the degree their more ardent advocates desire.

There is need for a well-rounded forward-looking national program of resource development and conservation. Construction and development of each part of this program should be geared to immediate and long-time national needs, to Government fiscal policy, and to general economic conditions. Contributions of each to the national welfare should be evaluated in terms of broad economic and social objectives. Irrigation development in my opinion, should have an important role in such a program.

ACREAGE LIMITATION IN FEDERAL IRRIGATION PROJECTS WITH PARTICULAR REFERENCE TO THE CENTRAL VALLEY PROJECT OF CALIFORNIA

VARDEN FULLER
University of California

FOR the past several years the acreage limitation feature of federal reclamation law has been in controversy in the Central Valley Project of California. The issue arises primarily because this project deals with privately-owned lands, a good portion of which is already developed under irrigation and is in large ownerships and large operating farms. The project is needed to supplement presently inadequate water supplies and to integrate the uses of the water resources of the entire Central Valley Basin. No acreage limitation was contained in the state legislation of 1933 which originally authorized the project. But the state did not build the project; rather, the assistance of the federal government was sought and in 1935 it was authorized as a federal project subject to reclamation law. Since the people of the state had had little previous experience with federal reclamation, they had little reason to be well acquainted with reclamation law. Only in 1943 and 1944, when construction was well advanced, did landowners become generally aware of the acreage limitation. In the first several years following the initiation of the project, the Bureau of Reclamation, although it clearly should have done so, made no attempt to contract its prospective water supplies nor forthrightly and officially to inform the people of California that all provisions of federal reclamation law were applicable.

Much of the discussion as to the applicability and merits of the acreage limitation within the state and in Congress has been highly controversial. Prominent persons and organizations are lined up on one side or the other.¹ Unfortunately, the controversial atmosphere has obscured some all-important and fundamental problems and has delayed study and consideration of them. Inevitably, both proponents and opponents of the acreage limitation have had to assume extreme positions. It may perhaps truthfully be said that the acreage limitation as it now stands has neither the virtues

¹ For an excellent discussion of the political issues and the positions of parties in respect to them, see Taylor, Paul S., "Central Valley Project: Water and Land," *The Western Political Quarterly*, University of Utah, vol. 2, no. 2, June 1949.

that its supporters ascribe to it, nor the diabolical attributes that its foes ascribe to it.

Purposes of Acreage Limitation

The quarter section (160 acres) has long been a prominent feature in American land policy. Under the Pre-emption Act of 1841, an applicant could file a claim within the limit of 160 acres if he were the head of a family, or a man over twenty-one years, or a widow, but such applicant had to swear that he had no more than 320 acres of other land. Under the Homestead Act of 1862, any single person over twenty-one years, or any person who was the head of a family could acquire title to 160 acres of public land provided he met the residence and improvement requirements. These basic 160-acre limitation features were carried forward into the Reclamation Act of 1902, with the additional power conferred upon the Secretary of the Interior to adjust the limit in an ownership that would be eligible to receive federal irrigation water between the maximum of 160 acres and a minimum of 40 acres. Such a limit was to "represent the acreage which, in the opinion of the Secretary, may be reasonably required for the support of a family upon the lands in question . . ." (Sec. 4 of the Act of 1902). Thus, it appears that the framers of reclamation law intended not only to carry forward the maximum ownership concepts of the Pre-emption and Homestead acts but also to introduce further limitations to reflect differential productivities of land and the value of federally developed irrigation water—these considerations being further equated to the income needs of a family.

In irrigation law and philosophy, the acreage limitation has been expected to serve the dual and mutually consistent purposes of being a formula for the broad distribution of publicly financed benefits and an instrument of achieving family-owned and operated farms. It has been and continues to be expected that the ownership unit and the farm operational unit are one and the same thing, and that the owner will be the operator of his unit and no other. But apart from the determining of income needs and the unit to meet them, there are several problems here: one is in the aggregation of individuals that may constitute the family; another lies in the question of whether the owner will work his land or lease it to another; still others lie in the disposal of privately-owned lands in excess of the eligible acreage.

The basic reclamation statute is now almost a half century old. It has been amended and supplemented at least a dozen times in general legislation and additionally in legislation specific to individual projects. The vast detail of 47 years of legislative, administrative, and judicial experience incorporating the adaptations and concessions made in particular projects contains both affirmation of and divergence from apparent original legislative intent. Although acreage limitation as a general proposition has remained intact, many details as to its application have been changed both legislatively and administratively. As a result, the sort of farm unit now eligible to receive federal irrigation water differs materially from the unit as originally contemplated.

In summarizing the characteristics of the eligible irrigation unit as they were first conceived and in comparison with the provisions and administrative interpretations of current law, the contrasts are as follows:

Ownership Unit: Originally, as under the Pre-emption and Homestead acts, it was essentially a family concept with the rights resting in the head of the family or in a person over twenty-one years having the prospect of becoming the head of a family or a spouse of the head; the individual had to be a real person. Now the ownership unit is any person, without regard to family status, male or female, of any age, real or corporate.

Acreage Eligibility per Ownership Unit: Originally, based upon determination of the Secretary of the Interior of the amount of land needed to meet the income needs of the family, the acreage per ownership unit was set between 40 acres and 160 acres. Now, eligibility is 160 acres for any individual ownership, without regard to the productivity of the land or the income needs of the ownership unit.

Occupancy and Operation: Originally, the individual holding the water right was required to occupy the irrigation unit and live thereon or within a fifty-mile radius. Now, there are no residence or occupancy conditions whatever.

Disposition of Excess Land: In the early administration of the law, water was delivered only to units small enough in total to meet the eligibility requirements. This meant that if a holding was too large, the excess land had to be disposed of before water was supplied to the nonexcess. Now, any individual owner is entitled to water for 160 acres even though he may own 10,000 acres within a

project. Furthermore, water may be received on the entirety of an ownership, irrespective of how big it is, for ten years provided the owner enters into a contract agreeing to dispose of the excess within or at the end of the ten-year period.

With the changes that have occurred as to ownership, occupancy, and the disposal or nondisposal of excess land, it is quite apparent that the operating farm unit may differ very greatly from the irrigation eligibility unit. The operating unit may now include the irrigation acreage limit of each of any number of individuals holding fractional interests in co-tenancy plus excess lands either with or without project water plus any number of absentee ownerships that may be rented and brought into the operational unit.

The maximum divergence between original objective and possibilities under current reclamation law has not been manifest in other projects. Partly, this is for the reason that many of these projects were initiated under earlier law; partly, it is because several of them are covered by more restrictive legislation specific to the project. But more important, most of the projects are located within areas where the scale and type of farming is more nearly in accordance with the characteristics of the traditional family farm than is the case for much of the prospective irrigation service area in California. Here, the many large ownership and operating units already developed into intensively cultivated irrigation farms will quite obviously be subjected only to the minimum accommodation to the acreage limitation that is required under the law. Reciprocally, therefore, the widest divergences from original intent will undoubtedly come to be seen in the application of the limitation in the Central Valley Project.

Application of the Acreage Limitation to the Central Valley Project

The possibilities of setting up operational units much larger than the individual irrigation limit of 160 acres were described above. To what extent will owners and operators in the Central Valley area take advantage of these possibilities? This question obviously cannot be answered in advance but practices of the past should give some indication of the general characteristics of the situation that will come to prevail in the future.

Practices established in the past are indicated by a survey made in 1945 by Edwin Wilson and Marion Clawson, then of the Bureau of Agricultural Economics, of the interrelationships between

ownerships and operating units in the valley floor area of Madera, Tulare, and Kern counties,² which is the principal prospective water service area. The data were derived from AAA records which relate to the year 1940. This survey covered a total of 10,436 farm operating units for which the corresponding number of ownership units was 12,941, or an over-all ratio of $1\frac{1}{4}$ ownership units per operating unit. On one half of the ownership units, ownership and operation were perfectly concurrent, i.e., the owner farmed his own unit, renting no land to or from others. Tenants operating the entirety of an ownership but owning or renting no other land accounted for another 10 percent of the ownership units. Thus, a total of 60 percent of all ownership units was also the operating unit. But these arrangements were heavily confined to the smaller ownerships and, therefore, accounted for only a small fraction of the total land in farms.

With ownerships above 320 acres, the extent of identity between the ownership and the operating unit declines as size increases. From around 640 acres and up, the evidence is that owners become more concerned with renting than with operation.

Of all land in the operating units above 640 acres but less than 5,120 acres, more than half is rented. From 640 acres to 1,280 acres in operating farms, 57 percent is rented land; from 2,560 to 5,120 acres, 66 percent is rented, but the very large operating units over 5,120 acres are based primarily on owned land.³

The study included fifty-one farms which operated between 2,560 and 5,120 acres, of which only ten were based upon a single ownership, twenty-six were operating from two to ten ownership units and fifteen were operating more than ten ownership units.⁴

If, in the future, the practices of the past as revealed by the study of Wilson and Clawson are continued, the operational unit receiving federal water may quite well be several times the individual ownership limit. A community ownership of 320 acres, if added to by leasing land in the same ratio as now prevails for this size group, can be built into an average operatorship of approximately 600 acres. A unit combining the individual ownerships of a man and wife and two children and adding the average ratio of

² U. S. Bureau of Agricultural Economics. *Agricultural Land Ownership and Operation in the Southern San Joaquin Valley*. Berkeley, 1945. 100 p. Processed.

³ *Agricultural Land Ownership and Operation in the Southern San Joaquin Valley*, op. cit., p. 71.

⁴ *Ibid.*, p. 72.

rented land applicable to this size group could be built into an average operatorship of approximately 1,500 acres.

The practice of using rented land from several ownerships to build up large operating units is thus well established in this area. Beyond the possibility of combining ownerships, there are the additional opportunities of continuing to operate the excess acreage without project water or of operating the entire acreage for ten years with project water, received under a recordable contract. The combined effect of these possibilities of operating farms far in excess of the individual acreage eligibility cannot be forecast at this time. There seems to be no good reason why multiple leasing will not continue under federal irrigation, but the extent to which excess acreage will be kept in the operating unit, either with or without water, cannot at present be known. This is because only a small proportion of the total water supply is presently under contract and until all water is contracted, the project service areas will not be known, and until the project service areas are known, the amount of excess land cannot be known. Furthermore, whether the holders of excess land will want to operate it without water or will sell without having established water right, or will apply for project water under the recordable contract are decisions they will probably defer until the change in ground water levels and the assessment practices of the districts with respect to acreages not under service are known or can reasonably be forecast.

Although there are factors yet undeterminable that will influence the effect that acreage limitation may have on the size of operating units, there is little prospect that operating units will be restricted to anything like the individual irrigation limit of 160 acres. Apparently, there will be considerable opportunity to maintain federally-irrigated operating units of from 320 to 1,000 acres without much difficulty. Adding to that such excess lands as may be permanently retained without project water further increases the operating unit. It seems most doubtful, therefore, that the acreage limitation as such will contribute significantly towards the expansion of family-size farm units in the Central Valley Project area.

Conclusions

(1) Present law on acreage limitation—while being in broad terms the result of affirmation and reaffirmation, legislatively and administratively, of the initial act of 1902—now diverges in details

of such importance as to impair the realization of the objectives originally hoped for.

(2) At least in projects where private ownerships are large or other conditions are favorable to large-scale farming, the basic law cannot be expected to serve as a means of achieving family owned and operated farms. This does not mean, however, that supplemental legislation for specific projects prepared in advance of construction cannot be the means of realizing this objective.

(3) As long as tax-supported federal irrigation activity involves subsidy and originates benefits that are privately realizable by only a very minor proportion of the population, some sort of formula for the equitable distribution of such benefits is clearly needed. Although the per-capita benefit that can be realized has unquestionably been greatly increased during the past forty-seven years of legislative and administrative experience, and eligibility has shifted from the little fellow to a per-capita basis, the acreage limitation still stands as a formula for the broad distribution of benefits. For the Central Valley Project, the diffusion of benefits will apparently be realized less in terms of expanded opportunities to own and operate farms than in terms of opportunity to acquire and retain land on a rentier basis.

DISCUSSION

GEORGE W. BARR

University of Arizona

Dr. Fuller's paper comprises a good statement of the operation of land tenure under the acreage limitation clauses in the Reclamation Act of 1902 and as subsequently modified. The purpose of federal irrigation activity as given by Dr. Fuller is subject to question. He stated the "primary purpose" of this activity "is to create farm homes on which the owning family will live and work and earn an acceptable income." This is a sociological objective. Back of the sociological objective and even more fundamental must be an economic objective: the creation of additional wealth-producing properties. Why should not consideration be given to an ownership or operation pattern that will bring most production or most wealth to America? Such a pattern would ensure earliest repayment.

In another part of his paper Dr. Fuller states "... that while federal irrigation law is now stripped entirely of the concepts of a family holding and an economic unit capable of providing a family income, the legislation for specific projects ... may contain limitations incorporating both ideas." The reader should note that the so-called minimum economic unit to which reference is made is "economic" only in the mind of a sociologist. A minimum economic unit more sound from the standpoint of society comprises that sized farm which will keep the operator fully occupied, or in other words which will utilize the full physical and managerial capacity of the operator. Incidentally, this latter minimum unit is the more readily determinable

and it is this unit which is becoming larger as mechanization and specialization develop.

In his closing remarks Dr. Fuller implied that the acreage limitation through its control on sales prices of excess land may reduce "speculation based upon the unearned irrigation value increment." It appears, however, that unless land is appraised and acquired by government before irrigation development is started, the original owners of the land, both large and small, will be the recipients of the largest unearned increment of value because of the enhancement of value before sale.

Mr. Selby in his paper has challenged the importance of irrigation in the economy of the West. His most extreme statement minimizing the value of irrigation follows: "the net result of additional irrigation development is chiefly more production of beef cattle and sheep than otherwise would occur." While it is conceded that irrigation development has made possible certain increase in the poundage and in the finishing of livestock produced in the West, to attempt to convert the net result of additional irrigation to pounds of beef and sheep is certainly a great simplification of the vast irrigation development that has occurred in the West.

Actually, in the twenty years ending with the year 1940 during which irrigation expanded widely, sheep numbers by census count decreased six percent in the eleven western states and numbers of beef cattle decreased 15 percent. It is not logical to take a matter like irrigation development entirely out of its setting. Irrigation development must be considered as a part of the development of the West. Here a new empire has been created. The same initiative, energy and capital that built the cities of Los Angeles and Seattle, that built the San Francisco Bay bridges, that built Grand Coulee, Bonneville, and Hoover dams, that developed the copper mines of Arizona, the coal of Utah, the ferrous and gold mines of Colorado, also built the irrigation works, leveled the land, and made the desert blossom with something other than cacti.

True, there might still be an America without Bonneville, without Los Angeles, without the Bay bridges, without the pleasure highways of the West. America in 1949 could import its copper from Mexico and South America. It might get its fruits and vegetables from Central America. For the love of nature its people might travel the highways of France and Italy and Switzerland. Under such conditions the production and industries of the West would not be competing with the production and industries of the eastern states—but that America would not be the world-dominating America we know at the midpoint of this twentieth century.

DISCUSSION

EARL L. BUTZ

Purdue University

The typical Midwestern attitude toward the increasingly costly reclamation projects in the West can be, I think, summarized in a few words. The attitude is changing. Typically, the people of the Midwest and the East believe in the conservation and development of our national resources including water. However, they have been familiar only in a general way with the scope, benefits, and costs of western reclamation projects. Frankly, they have been rather apathetic toward the entire question of irrigation of

western lands. Moreover many of them have sort of had the feeling that many of the products of irrigated lands in the West were supplementary to the staple agricultural products of the Corn Belt, such as out of season fruits and vegetables which move East in great volume.

Two recent developments are changing the typical attitude of the Midwest and the East toward further irrigation at federal expense. First the increasing federal tax burden paid by all of us, including Midwestern farmers, is causing many people to take a second look at large items of federal expenditure, especially where no direct benefits accrue to the person so aroused. The second development, which is upon us now, will really arouse a flood of protests in a year or so. Our farmers and our farm leaders, and a few college personnel also, will not welcome curtailment of output by government fiat in an area of natural production where water comes free, while at the same time they are being taxed to expand output in unnatural and high cost areas. And these Midwestern farmers will be further aroused when they discover that the net effect of much of the new irrigation in the West will be to increase output of competitive products such as livestock and dairy, as Mr Selby pointed out in his paper.

The Midwest, or any other section for that matter, has no quarrel with reclamation that pays a reasonable share of its way. After all, all sections of the country have had, and now have, considerable government enterprise of this nature. This was a basic principle of the original Reclamation Act of 1902. However, when reclamation becomes an end in itself, on projects that are obviously marginal, to state it generously, from a cost analysis point of view, then we need a new look at the entire process.

We have moved a long way from the subsidy provided in the Act of 1902, namely that project costs were made repayable without interest charges, to the philosophy currently held by many proponents of reclamation that an irrigation project is feasible if there is reasonable assurance that water users will be able to pay annual operating and maintenance expenses, with no charge for construction, as pointed out by Mr. Fuhrman.

It is deplorable that we tend to allocate an ever increasing share of irrigation costs against such non-reimbursable items as flood control, recreation, wild life and game development, and the like, in order to justify another irrigation construction project. This type of subterfuge is usually not in the long time public interest, if it results in uneconomical expenditure of public funds and an unnatural allocation of our production resources in agriculture. If we are going to curtail output of food and fiber in our natural and low cost producing areas, then we should not at the same time resort to a form of public deception in an unrealistic cost allocation to justify huge federal expenditures in additional irrigation projects.

Let's be realistic. If the nation faces an actual food shortage, then by all means let us pursue aggressive programs to reclaim new areas, even at considerable federal expense. But if we are going to act like we already have too much food (and that's the way it looks now), then let us produce our needs as economically as possible, wherever we can.

Let's be consistent. Let's not make reclamation an end in itself, particularly in cases that are clearly marginal or submarginal, but let's make the agricultural part of our reclamation program subordinate to the overall food and agricultural policy of the nation.

WESTERN RANGE LAND USE AND CONSERVATION PROBLEMS

MONT H. SAUNDERSON
U. S. Forest Service

SUPPOSEDLY, now is a time when conservationists are seeing "bogey men" under beds and in dark closets. I'm not going to ask you to peer into such places with me, but I do want to draw a word picture of certain trends in the western range resources, to discuss the economic factors in those trends, and to relate those trends to some significant changes in the operation and management of western stock ranches.

In the general picture, the western range is a declining resource. So definitely is this true that some parts of it can be written off, as having passed or as rapidly passing the point of feasible rehabilitation. This decline is evidenced at the one extreme by rapid and violent erosional destruction of range land and soils; at the other extreme by shifts in the native plant associations to a somewhat lower, though not necessarily less valuable, range plant ecology. In between these extremes we see some widespread displacements of native range plants by exotic range plants that are much less useful as range forage and as soil and moisture conservers. We see some significantly undesirable shifts in the native range plant life of some large range areas.

Some deny these important changes and say that we have not any appreciable decline in the western range resources. Those who express this belief point to the long run uptrend in our western population of range and pasture animals, to the trend of increased calf and lamb crops and higher weights of market animals, to the higher number of animals marketed in ratio to the stock cattle and sheep population, and to the USDA index of range conditions. I refer here to the range conditions report of crop and livestock estimates in the Department. These reports give no indication of a long time trend. By their nature, they could not be expected to do so.

Let's examine, briefly, these "refutations" of statements and beliefs that there has been considerable and widespread loss in western range resources.

Fifty years ago scarcely any of the beef cattle of the eleven western states could be classed as farm cattle. Now, more than half of them must be so classed. At the turn of the century, crop feeds and

protein range supplements were little used in the winter maintenance of range cattle. Now, these feeds account for three or four months of the year's feed and forage supply. Western range lands, excluding those lost to cultivation, now probably yield considerably less grazing than they did forty or fifty years ago. The increased use of crop feeds and the use of more efficient animals obscure this change in the resource, as far as livestock production effects are concerned. We must recognize, too, that for some types of range the livestock grazing use and the weights of the animals marketed may be well maintained for quite a period of years, while, at the same time, adverse changes occur in the soil-holding range plants and in the soils.

Now, let's have a look at some of the changes that have taken place out on the land in the decline of western range resources, and let's see how these changes in the resources have caused consequent changes in the economy of the stock ranches. In presenting this picture, let's use a concept of natural geographic regions of the West. These regions coincide, in a general way, with the main range forage types of the West.

Range resources of the Northern Plains, east from the Northern Rocky Mountains to the ninety-eighth meridian and south from Canada to the Platte River, are neither greatly changed nor much deteriorated, except for the "go back" lands that were once farmed. This is the only one of the main range types of the West that has not undergone widespread change through use. The reason for this is, principally, a relationship between the ecology of this range type and the economics of its use that favors moderate grazing. Heavy use of this range changes it from an association of the mid-grasses and the short grasses to a pure short grass type. The short grasses are sod formers and good soil protectors. Under heavy use the short grasses often form a dense turf that yields only a small growth volume of range forage, and that is seasonally unbalanced. The short grasses are the warm weather grasses, and the mid-grasses are the cool weather grasses that afford much of the spring and fall range growth.

Thus, we see that overuse of the Northern Plains mixed prairie range type brings a quick economic penalty, before the occurrence of any considerable range plant and soil losses. It doesn't pay to overgraze this range, and that situation is usually definite and obvious. Too bad that we do not have this favorable relationship

is a pen good range plant ecology and good ranch production overomics for the other main range types of the West, but we do rapi

Large land resources of the Central Plains, from the Platte Noer to the southern limit of the high plains in northern Texas, In'have an ecologic and use relationship nearly comparable with lase of the Northern Plains. However, the production possibilities at the Central Plains for grain sorghums, dry land corn, and winter hheat pasturage, have induced widespread adaptation of stock anching toward stock farming. As a consequence, good maintenance of the native grassland is of less economic consequence for many of the stock growers. Native pastures are overused and the short grass sod furnishes some summer grazing that fits in fairly well with crop feeds and pastures and serves as an "exercise ground" when the livestock must be out of the fields. However where the Central Plains range lands are used in ranches, the economics of their use is comparable with the Northern Plains. The favorable economics of moderate use is, however, somewhat less definite, since the cool weather mid-grasses are less important and the warm weather short grasses more important in the year's range forage production.

Southern Plains range lands have shifted rapidly during the past thirty or forty years from a grasslands appearance to a brushlands aspect, and from a predominance of cattle grazing to a predominance of sheep and goat grazing. This shift to sheep and goats has been especially pronounced in the Texas Edwards Plateau; also in the Trans Pecos parts of Texas and New Mexico. The total cattle population of Texas did not decline very much during the period of this shift, but the center of Texas cattle population has shifted eastward, out of the range country. Texas sheep numbers nearly tripled between 1920 and 1940, and this has been associated with the shift in the Southern Plains range type to brush, shrub and weed growth and a diminution of the perennial grasses.

Probably this shift in range plant association and the consequent change in ranch economy have not materially lowered the income of the ranches, for the present. But, loss of the perennial grasses as soil protectors has greatly increased the soil erosion problems of Southern Plains range lands.

Let's turn next to the Rocky Mountain Region, which lies between the plateau country to the west and the Great Plains to

the east. Range resources of this region consist mainly of the hill grasslands, of the bunchgrass cattle feed in the ponderosa zone of the mountains, and of the sub-alpine and alpine sheep of the higher mountains. Most of these resources are in a different trend of range plant ecology and soil conditions. For most of the region, however, the consequence of this trend in the range resource does not yet show up in changed ranch economics. As the perennial bunchgrasses have diminished from overuse, the livestock production has been fairly well sustained on the browse feed and on the annual grasses and weeds that are not good soil protectors. Soil erosion can, in this situation, reach an advanced stage before the livestock production and the ranch economics are materially lowered. This is the situation that jeopardizes the watershed land of much of the Rocky Mountain Region, the headwaters of the main streams of the West and the source of much of its water.

We look next at the range resources of the Intermountain Region, the region westward from the Rocky Mountains to the Sierras and the Cascades, and northward from the Mogollon "rim." Most important of the several range types of this region is the great sagebrush range type. It is greatly changed, and the economics of its use is changed accordingly. Once the sagebrush stands were open, with a good understory of the native perennial bunchgrasses. In its early use this range was, principally, cattle range. Much of it was good, season-long cattle range. Overuse for cattle grazing took out the bunchgrasses, the sagebrush stands thickened, and, throughout the eighty million or more acres of this range type, there is now an understory of the Mediterranean brome grass commonly known as cheat grass. This cheatgrass grows early in the spring and dries to a "fire tinder" by June. This change has made this range a spring range instead of a season-long range. It can be used for range livestock production seasonally, in the spring and early summer when the cheatgrass is green, if such spring range can be fitted in with other seasonal ranges, meadow grazing and crop feeds to complete the year's operation. The cheatgrass isn't much good after it dries. Many a cattle ranch has, because of this change in the sagebrush lands, had to reduce cattle numbers drastically and depend much more upon summer grazing of the ranch hay meadows.

In the more arid parts of this range type, such as southern Idaho and western Nevada, cheatgrass range fires are destroying the sagebrush, thus resulting in a pure cheatgrass stand. Cheatgrass

is a poor soil protector on erodible slopes, especially when burned over. Competent range conservationists say that they foresee a rapid trend to true desert conditions for much of this land.

Let's look at California range resources and ranching next. Northeastern California range lands are similar to those of the Intermountain Region, so we will confine our attention to the range lands that rim the California central valley—the Sierra foothills and the hills of the coast mountain ranges. Two important changes have occurred in the range resource of what is now known as the California annual grass range type. This range resource was once an association of native perennial grasses and native annual grasses. Now it consists entirely of annual grasses, native and exotic—the native perennial grasses now occur only in relic stands. In the upper or brush zone of this range type, range brush burning has caused accelerated soil erosion on much of the land in the brush zone.

Growth and use of the California annual grasses are highly seasonal, from November to June, or during the season of winter rains. Stocker cattle are imported in large numbers from nearby states to use this highly seasonal range grazing, and the breeding herd part of the ranch operation is maintained through the summer on the harsh, dry oat and brome grasses, with addition of a protein supplement to the range grazing. Perennial grasses, such as were once a part of this range type, would permit a larger breeding herd operation, with better summer grazing, and a decrease in the speculative purchase of stocker cattle to use the highly seasonal range forage of the annuals.

In the southwestern region, south of the Mogollon rim and between the Colorado River and the Rio Grande, we see a startling contrast between the desert shrub lands and some spectacular semi-desert grasslands in southeastern Arizona and southwestern New Mexico. These grasslands have remained in reasonably good condition.

We are told by competent ecologists, however, that the present southwestern desert shrub lands once had a grasslands aspect; that, before they were long overused they were in a period of soil formation and ecologic uptrend. Now, we see the rapid eroding out of the flat alluvial valleys and drainageways of the streams. An illustration of this is the rapid destruction of the lands of the Rio Puerco drainage, and the consequent high rate of sedimentation into Elephant Butte reservoir. Some of the "desert" lands of this region

that once supported reasonably good yearlong cattle grazing now can be grazed only with stocker cattle in the occasional winter and spring season when favorable precipitation causes the desert annual plants to grow in volume.

So much for our word picture of what is happening to western range resources and the consequent change in ranch economics.

Perhaps considerable loss in the western range resources should not be viewed as of too much consequence, nationally. All of the beef cattle on both the farms and the ranches of the eleven western states account for probably not more than fifteen to twenty percent of the total U. S. beef production tonnage. However, these states produce about a third of the feeder animals, nationally, that go into the feedlots. Probably the foreseeable loss in western beef production as a result of losses in range resources could be offset by some relatively minor changes in corn-belt agriculture.

Continued losses in western range resources will, however, be of real consequence to western economy. Consequences would be a materially lowered income from livestock, and, much more important, some far-reaching adverse effects upon western water resources. I wish to say more about that later on.

It seems probable that we are going to have the conditions for further and considerable loss in western range resources. Likely, we are going to have the profit incentive for carrying as high a number of beef animals as possible. Present prognostications regarding the increase in the human population of the U. S. during the next twenty-five years indicate that we may have need for a beef cattle population one-fourth greater than our past all-time peak. Beef is made mostly from grass. Grain feed accounts for probably not more than fifteen percent of the total U. S. beef production tonnage. Where will we find the increased range and pasture production for any such beef cattle production? Probably in part, by continued pressure on the western range resources.

One of the currently live policy questions in the use and conservation of western range resources is that of private versus public ownership, especially for the lands in Federal public ownership. One viewpoint concerning this issue is that overuse and mismanagement of the resource are more likely to occur on lands in public ownership because of insecurity of tenure and lack of management control by the grazing users. This viewpoint argues for private ownership of all lands used for grazing, perhaps excepting the lands

of multiple uses and significant public interest, on the grounds that the profit incentives of entrepreneurship will best conserve the range forage and soil resources. Corollary with this view concerning private ownership, it is said that for the lands of high public interest that must remain in public ownership, adequate security of tenure for the grazing users will give the needed economic incentives for maintenance of the resource through private entrepreneurship. We note here, as a matter of information, that the present ownership of the range resources of the eleven western states is approximately two-thirds private and one-third public. This is in terms of production rather than of acreage.

It is my belief that, until rather recently, there has not been any significant relationship between the kind of ownership and the good use of western range resources. Some of the best conservation has been on privately owned lands; some large areas long in private ownership have been badly used—the Texas Trans-Pecos District, for example. Until recently, numbers of livestock grazed on the public lands closely paralleled the trends of total western cattle and sheep numbers. Since 1940, however, the grazing of cattle on the western national forests has been reduced during the period of uptrend in western cattle numbers. This is in contrast with the period of the first World War, when nearly a million additional head of cattle were admitted to the national forests for grazing as a “war emergency measure.”

It seems probable that the most important causes of misuse and loss of western range resources are the economic influences and the lack of management “know how.” Most important among the economic influences I would rate the considerable lag between ecologic and economic trends, for most of the main range types; the wide production swings of an arid region and the tendency to base financial structure on the favorable periods; the problems of land tenure in good management, especially for the private lands.

Lack of management “know how” as a cause of loss in western range resources probably can’t be changed very rapidly. Meanwhile, we foresee the probable economic basis for continued use pressure on the western range resources. What are the possible policy and program alternatives for better use and conservation of these resources?

In thinking about these policy and program alternatives, let’s look first at the public lands. Principally, these lands are the 135

million acres of the national forest land of the eleven western states, and the some 180 million acres of the lands remaining in the public domain when the Taylor Act was passed in 1934. Since then, some 140 million acres of these lands have, under this Act, been included in Federal grazing districts.

National forests are, mainly, the western mountainous uplands. These lands are not all timbered: in fact, commercial timber resource accounts for less than half of their area. Timber, brush, shrubs and grass cover most of the western national forests. About half of their area is used for the grazing of domestic livestock.

Because of their watershed aspects, the western national forest lands are heavily fraught with public interest. These lands originate nearly three-fourths of the western water supplies available for agricultural, urban and industrial use in the arid West. Western mountainous uplands above 6,000 feet in elevation yield most of the water. Misuse of the upland watershed lands and consequent changes in vegetation and soils can greatly alter the hydrology of these lands. Surface runoff can be increased at the expense of the ground water storages, time of delivery of the runoff can be considerably changed, quality and useability of the water can be damaged by increased sedimentation.

Grazing use of these lands should be such as will not interfere with good watershed use. It might be argued that, with long-term and secure tenure for the grazing user, profit incentives in the grazing use and the maintenance of good watershed conditions would be coincident. However, for most of the national forest grazing, the usual calculations of production economics do not favor the maintenance of plant and soil conditions needed for good watershed management. Thus, we arrive at the conclusion that the grazing use of the western national forest lands must be constantly subject to review and revision by the administrative management agency, and that the grazing users must accept any changes needed for the watershed use and other uses of high public value.

The question has been raised whether the upsurge of western deer and elk populations during the past four or five decades has contributed materially to the grazing overuse of western wild lands. In localized situations this appears to be true, but it isn't very important in the general picture for the upland range resources. Deer and elk use many browse feeds not much used by the domestic livestock, and the deer eat browse in preference to grass. Much of

the upland summer range used by deer is too rough and inaccessible for range use by domestic livestock.

Somewhat in contrast with the national forests, nearly all of the lands of the public domain are used for the grazing of domestic livestock. These are lands of low grazing capacity—about six head of cattle per section or twenty-five head of sheep per section on a basis of yearlong grazing—and in the past they have been below the margin for investment in management facilities and payment of taxes by private ownership. Livestock prices and ranch earnings of recent years have lifted many of these lands, perhaps temporarily, above the margin for private ownership. As a consequence, there has been a considerable demand for policy and legislative changes to permit ready purchase of these lands by grazing users.

Some of these public lands have considerable value in wildlife and recreational uses. They are the winter and spring ranges for many of the western deer herds. These are not watershed lands in the sense of water producing lands, but some of them have become a subject of considerable public interest and concern as sources of sedimentation. As an illustration of this, it is estimated that the Rio Puerco drainage of the Rio Grande yields 60 percent of the sediment and only 10 percent of the water entering the Elephant Butte reservoir. Competent conservationists state that the arid lands of the public domain have, because of their erosion and sedimentation condition and potential, become the most important problem lands of the West, and that their grazing use must rapidly be subordinated to the necessary rehabilitation and conservation measures that are going to require heavy public expenditures in the general public interest.

For the conservation and good use of the *privately-owned* range resources of the West, we need a good program of educational and extension work in range management. In the Northern and the Central Plains, especially, such work should be closely associated with extension work in livestock ranch production economics, for in these regions it is generally true that range conservation pays dividends, within the time of ordinary foresight and usual business calculation. For most of the other regions of the West, extension work in range management must be closely integrated with the work of the conservation action programs that can use public funds for resource conservation in the general public interest. For here often the ranch production economics results of range land

conservation seem remote and uncertain, due to inherent factors of ecologic and economic relationships, or because the conservation problems have, in our past exploitative rural economy, outrun the capacity of individual entrepreneurship for investment and waiting.

DISCUSSION

WILLIAM N. ANDERSON
Bureau of Land Management

I must confess that Mr. Saunderson gave me quite a start when he said that our range resources have declined to the extent that some parts of them can be written off as having passed or as rapidly passing the point of feasible rehabilitation.

While the Bureau of Land Management has not yet written off any of its depleted areas as not feasible of rehabilitation, we are admittedly stumped for the present on what to do toward rehabilitation of much of our cheatgrass invasion where recurrent burning so far has defied prevention, where repeated burning means continued decline, and where reseeding by present means is not practicable. We are also stumped on what to do about widespread gully erosion in areas where direct structural treatment is financially out of the question.

These, however, appear to be problems of technique rather than cases where the range has deteriorated so far that it will not respond to treatment where treatment is feasible. For example, an area near Bliss, Idaho, was severely depleted for many years by heavy over-grazing and recurrent burning. Vegetative cover a few years ago declined to a point where wind erosion took over and dune formation began. Despite this advanced state of depletion, reseeding treatment reclothed this area and controlled the erosion in two years' time. This experience indicates that proper management and rehabilitation efforts should succeed in preventing declines to "true desert" conditions in this areas as long as precipitation continues at present normals.

Observations in grazing districts indicate that the rate of decline in the range resources has been at least slowed down, and in some areas the trend has been reversed. Nevertheless, still further large readjustments in livestock use must be made in order to entirely halt the decline.

A brighter aspect is seen in many studies which have shown that net returns to livestock operators commonly increase when numbers of stock on over-used ranges are reduced to a point permitting forage recovery. Once an upward trend is established, numbers may be again gradually built up. By careful management the restored range can be made to safely carry even greater numbers than those under which it is now declining.

Despite these favorable signs, I cannot subscribe to the view indicated by Dr. Vass that upward trends in western livestock populations demonstrate a continuing healthy condition of the range as a whole. The point is not clearly demonstrable from production analyses because of the lack of

comparable statistics over a sufficient time period. Many changes have taken place which make it impossible to arrive at conclusions as to the degree the range contributes to increased production. Much former range land now is in crop production; increased livestock populations are supported by these crop lands; present western livestock populations include large numbers which do not use the range at all and others that use it but little; range cattle now are generally sold at much younger ages than formerly, etc. On the other hand, the ecological evidences of decline in such areas as the Edwards Plateau of Texas and the Central Valley foothills of California, noted by Mr. Saunderson, and the similar evidences seen in the continuing increase in sagebrush density throughout the intermountain area, are too frequent and extensive to be dismissed as isolated examples.

As Mr. Saunderson has pointed out, the importance of this decline is not reflected in grazing values alone, but in all associated values. The erosion problem on the Rio Puerco and its effect upon Elephant Butte Reservoir is but one of many examples which might be cited. Proper use of watersheds is essential, whether to protect downstream values subject to damage by flood, sedimentation of water storage or to protect the water shed itself from erosion. The additional importance attaching to proper range use for its effect upon ground water percolation is emphasized by current problems of lowered ground water tables in areas where pump irrigation supplements surface waters to a large extent. The vast areas of public and private ranges doubtless contribute significantly to these ground waters, since they often absorb more precipitation than they shed.

I cannot agree with Mr. Saunderson's suggestion that "Probably the foreseeable loss in western beef production as a result of losses in range resources could be offset by some relatively minor changes in Corn-belt agriculture," and that this decline would be important only to the Western economy. Resource economists commonly point to greatly pyramided benefits to the general economy deriving from relatively minor increments to new wealth from primary production. Is it not reasonable to assume that a loss of basic productive capacity of similar scale would be equally pyramidal in its adverse effect upon the general economy? I do not feel that we can dismiss the western range economy as unimportant to the nation. Certainly we cannot dismiss as inconsequential the combined effects of direct range production losses and associated losses in irrigated agriculture, power development and other associated values.

There can be no doubt that the natural human tendency—or perhaps I should say to this group the natural economic tendency—to overstock the investment-free, tax-free public ranges while protecting privately owned lands has accounted for much of the existing depletion on public ranges. It should be observed, however, that the reasons for this practice have been largely removed under the permit system on National Forests and on grazing district lands. Much of the formerly abused public range is now in individual or small-group allotments. The users have essentially the same incentives for careful use as on owned lands. Even on unallotted, common-use ranges the unauthorized user has been virtually eliminated, so there is

no longer occasion for the dog-eat-dog tactics which prevailed in the days of the open range.

With an assured tenure on grazing district range lands, the range user is expanding his natural interest in conservation to cover his whole set-up, including the public ranges. He realizes that his whole operation is no stronger than its weakest link. Hard-earned gains made on well-kept private lands are quickly lost on run-down public lands which supply the forage for his stock for a certain season. With well defined national conservation policies governing the use of these ranges, it would appear that the greatest danger of overstocking in the future will be on privately owned ranges, where economic circumstances might compel the owner to over-use in an attempt to keep land investments liquid.

There is no particular magic in either public ownership or private ownership—each seems to have found its place largely on the basis of the management and development needs and the productive capacity of the lands involved. The general lack of interest of present range users in buying the public lands, seems to indicate that the division between public and private ownership may become permanently stabilized at about present levels.

DISCUSSION

H. R. HOCHMUTH

Bureau of Agricultural Economics

It is apparent that the problems of the range area are many. Some will say that overgrazing is the primary problem, others point to tenure, or climate, or government land ownership as of greater importance.

Although not specifically stated one gains the impression from Mr. Saunderson's paper that there can be no great separation between ecological and economic trends. These two sciences always closely associated when applied to the management and use of the range resource are factors contributing to the wealth of conflicting viewpoints. The concomitant effects of economic and physical pressures on the ranching environment are not easily isolated.

One can recall statements by conservationists that in general the range has trended downward in productivity since 1890. If that be true then the effects have been obscured by the insidious advance of breeding, irrigation development, and management. The producer has not been convinced of overall range deterioration. The calf and lamb crops are higher than in the past and the livestock market weights by age class are superior to anything previously obtained. And so the chasm between producer and conservationist widens. Actually it is a socio-political-physical problem.

If we could devise a means of indicating proper land use in terms common to all factions, progress would be more rapid. The producers think more in terms of food and fiber production and income than in terms of overgrazing and plant indicators. To prove (to the producer) that overgrazing is present, conservationists should present significant differences in net production of meat between overgrazed and properly grazed ranges. And these differences should be ascribed solely to the forage production factor. The effects of feedstuffs, animal husbandry, and other non-forage

factors should be eliminated. At that point we could then be on common ground and separate fact from fable.

Mr. Saunderson has been pessimistic to the extent that we get a broad picture of range deterioration and poor land management. Everywhere there are examples of range lands that indicate good land use and management. It would be desirable to study these lands as examples of economic use of resources. The negative approach to good land use has not occasioned the desired objective.

Where Mr. Saunderson feels that range deterioration is widespread, Dr. Vass finds no such indications for Wyoming. Dr. Vass is inclined to take the producer viewpoint that it is uneconomic for the rancher to overgraze, therefore, in the long run, he cannot afford to do so. However, the statement that the Forest service ranges should respond in the same manner as do private lands seems erroneous. The private ranges of the west lie mostly at the base of or between mountain ranges. These ranges, of course, do not include the extensive short grass areas of the plains. For the most part the National Forest areas are highly seasonal ranges with rugged topography. In all aspects of use, management, multiple use, climate, and forage production they have no comparability with private range—unless that private range is intermingled. Particular management factors not applicable elsewhere must be applied to the use and administration of National Forest ranges.

Tenure may have a greater import on the problems of range economy than does overgrazing. Perhaps there is reason to wonder why in our system of free enterprise some public lands exist that do not differ in any important aspects from adjacent private lands. If the federal government wished to dispose of them by sale would the users buy them—would they return the tax cost over lengthy periods through climatic and economic depressions?

It is a well established principle in public land areas that some of the value of public range forage is capitalized into private investment. This is due to at least two factors; (1) the scarcity of certain types of seasonal range, and (2) the economic rent from public lands which is capitalized into private holdings. This would indicate that perhaps grazing fees are less than the full rent from such land. Furthermore because our land taxing system is less than perfect, private lands comparable as to site and use are taxed in like ratio. But private lands associated with public grazing privileges have economic advantages not available to lands lacking public grazing privileges.

Calculation of the value of an animal unit month of forage is liable to misdirection if one computes only on a forage or TDN basis. If we had a perfect competitive system for obtaining forage from public lands then the question of proper allocation of economic rent between various land ownerships would be academic. The Ricardian theory of distribution and law of rent has extensive limitations when applied to land in the public range states. It is difficult, to say the least, to calculate the residual return to land—land that may have no alternative uses—when the return to that land is dependent upon use of and return from other parcels of land. A grazing animal recognizes no tenure relationships.

THE OBJECTIVES, EFFECTS AND COSTS OF FEED GRAIN STORAGE*

GEOFFREY SHEPHERD

Iowa State College

THE United States Government has been conducting a feed grain storage program for nearly sixteen years—ever since the Commodity Credit Corporation was organized in October, 1933. We should be able now to appraise this program, and make recommendations for the future, in the light of specific experience as well as general economics.

In order to appraise the program properly, we need to know first what objectives the program was set up to attain, and whether they were appropriate objectives. Then we can match performance against objectives, and benefits against costs.

Objectives of Feed Grain Storage

The original objectives of the CCC storage program were set forth in a brief statement by Henry A. Wallace, then Secretary of Agriculture, in 1936. In his view, the chief purpose of the “ever-normal granary” was to stabilize supplies against variations in production due to good and bad weather.¹ The first Annual Report of the CCC, published in 1940, took in more territory. It listed “three fundamental functions of the Corporation’s loan program: Namely, to protect and increase farm prices, to stabilize farm prices, and to assure adequate supplies of farm products.”

Were these valid objectives for a storage program?

A storage program can't raise long-time price levels. It is obvious that the first objective is not valid. A storage program clearly cannot “increase farm prices” over a period of years. What goes into storage must eventually come out; and when it comes out, it will depress prices about as much as it raised them when it went in (if the demand curve is a straight line on arithmetic paper). A program to reduce production, or to destroy some of the production, can raise the level of prices over a period of years, but a storage program cannot.

A storage program shouldn't stabilize prices against variations in

* Journal Paper No. J1684 of the Iowa Agricultural Experiment Station, Project 1013.

¹ The Agricultural Situation, Bureau of Agricultural Economics, U. S. Department of Agriculture, XX: 1, January 1, 1936.

demand. It is not an appropriate means for evening out the effects of variations in general demand. These variations in general demand, due to wars, depressions, booms, etc. do not last merely for a year at a time, to be followed by a new situation the next year, like variations in production. They may persist through most of a decade, like the depression of the 1930's, or they may be very brief. It is difficult to forecast when they will come and how long they will last. Nobody can tell in advance, therefore, how much to store nor how long to store it.

Furthermore, a storage program to stabilize prices against variations in general demand would have bad effects on low income and unemployed groups during a depression. It would accentuate the paradox of want in the midst of plenty. The government would be withholding food and raising food prices, against the interests of its consumers, many of whom would not be getting enough to eat.

A storage program however can stabilize prices against variations in supply. It can stabilize the farm prices of durable products against unpredictable variations in production due to weather. It can do this by putting the excess over average production into storage in big crop years, and taking it out in small crop years. That is the proper function of a storage program.

The question is whether we need a storage program of this sort for feed grains.

In order to answer this question, we need first to measure the variability of feed grain production, and then to show the effects of this variability on livestock production. This will provide a basis for measuring the effects of a feed grain storage program. Then we shall need to measure the costs of the storage program. The final step will be to compare the benefits with the costs.

Variability of Feed Grain and Livestock Production

The variability of the production of feed grains is shown separately by crops in Figure 1.²

Corn is by far the most important of the four crops shown. It makes up from 50 to 60 percent of the total feed concentrate supply. The greatest change in corn production from one year to the next took place from 1947 to 1949, when production increased 35 million tons—more than 1.2 billion bushels. The variations resulting from the drouth years of the 1930's were almost as great. "Year-to-year

² BAE Neg. 43928-X, Ag. Outlook Charts 1949, p. 31.

changes in United States corn production during the past 30 years (1919-1948) averaged 408 million bushels, or about 15 percent of the average production for the period (2,635 million bushels)."³

In one way, this quotation understates the variation, from a storage point of view, since corn production occasionally changes in the same direction for two or three consecutive years. The coefficient of variation⁴ about the trend over the period as a whole was 14.1 percent. This means that in a normal distribution, a band ranging from 14.1 percent above average production to 14.1 percent below average production—a total range of 28.2 percent—would include 68 percent of the series of corn crops. Also, a range from $14.1 \times 0.67 = 9.5$ percent above and below average production—a total range of 19 percent—would include 50 percent of the series of corn crops.

The next most important crop, oats, appears to be less variable than corn. But this appearance is deceptive, resulting from the smaller average size of the oats crop. Proportionally, the coefficient of variation for oats—16.1 percent—is greater than for corn.

The full impact of the variation in feed grains production upon livestock production is cushioned to some extent by offsetting variations in the carryover from year-to-year, and by variations in imports. Figure 2⁵ shows the feed concentrate supply (production plus carryover plus imports). The picture here is distorted a bit by the fact that government storage programs were in effect part of the time, reducing the variation in market supplies to some extent. Yet the coefficient of variation over the period shown was 13.4 percent, nearly as great as the figure for corn production.

The effects of this variation in feed concentrate supplies on total livestock numbers is shown by the dashed line in the upper part of Figure 2. Other factors also affected the numbers of livestock fed, for example, the war in the latter part of the period. But Figure 2

³ "The Feed Situation," Bureau of Agricultural Economics, U. S. Department of Agriculture, December, 1948, p. 11.

⁴ The coefficient of variation—the standard deviation divided by the mean—is used here, to enable direct comparisons to be made among the different series, independent of the units in which they are expressed. The deviations are measured from trends fitted by the method of orthogonal polynomials.

A curve of higher degree was used whenever its use brought a significant reduction in the variance. Linear trends were used for feed concentrates, hogs on farms, total livestock, and pork. Second degree polynomials were used for corn and oats. A third polynomial was used for total meat.

This job was done by Joe Boyd at North Carolina State College.

⁵ BAE Neg. 46500A-X Ag. O.C. 1949, p. 34.

shows that the controlling factor was the total supplies of feed. No matter how high livestock prices go, farmers cannot produce more livestock than their feed supplies will support.

The numbers of livestock fed annually are shown separately by species in Figure 3.⁶ The coefficient of variation for total livestock numbers was 6.7 percent. Hog numbers were the most variable of any species. Their coefficient of variation was 14.2 percent.

Total meat production varied a little more than total livestock numbers, as shown in Figure 4.⁷ The coefficient of variation in this case was 8.6 percent. Pork production varied more than other meats; its coefficient of variation was 14.3 percent. Milk production was relatively stable.

In sum, then: The variation in corn and oats production (averaging roughly from 10 percent above to 10 percent below average production) does not cause much variation in beef cattle production nor in milk production; but it does cause an equal variation (from 10 percent above to 10 percent below average production) in hog and pork production.

Effects of Stabilizing Feed Grain Supplies

The objective of a feed grain storage program should be to smooth out the variations in feeds production by storage operations, and thus smooth out the variations in livestock production.

This smoothing out would have two effects. It would affect the income of feed grain and hog producers, and it would affect the cost of producing hogs.

The demand curve for corn is a straight line on arithmetic paper, with an average elasticity of about -0.65 . Simple arithmetic shows that a storage program for corn, in effect converting large and small crops to average crops, would increase growers' incomes between two and three percent. (Details omitted here.)

Most of the corn crop, of course, is fed to livestock, not sold as cash grain. The demand curve for hogs, which are the principal consumers of corn, happens to have about the same elasticity and curvature as the demand for corn. A corn storage program that stabilized hog production would increase hog producers' incomes in the same way that it would increase corn producers' incomes if they sold their corn as cash grain.

⁶ BAE Neg. 46824-X, Ag. O.C. 1949, p. 35.

⁷ BAE Neg. 43812-X, Ag. O.C. 1940, p. 37.

A feed grain storage program would also affect hog production, processing, and distribution costs. Hog and pork production varies fully as much as corn production. Variations in production increase production and distribution costs. Equipment adequate to handle the peak load stands partly idle when production is low, and idle equipment increases per unit costs.

A full quantitative study of how much the variations in hog production raise costs is a farm management and distribution problem beyond the space limits of this paper. But earlier studies indicate that stabilization, especially stabilization that was assured in advance, would reduce hog production costs perhaps two or three percent. It would also reduce the costs of distribution.

Costs of a Feed Grain Storage Program

Corn is by far the most important feed grain crop. Oats is the second. It is cheaper to store corn on the cob than threshed oats. For these reasons, stabilizing corn supplies, with an allowance for oats too, would provide reasonably complete stabilization of total feed grain supplies at the lowest cost.

Complete stabilization of the market supplies of corn would hardly be practical. From 1870 to 1900, storage stocks of corn up to a billion bushels in size would have been large enough to stabilize corn supplies. During the decade from 1900-10, however, seven large corn crops occurred in succession, and the stabilization stocks would have increased to about two billion bushels. In the 1920's they would have grown larger yet, to nearly three billion bushels. Yet they still would not have been large enough to fill in the gap caused by the succession of four short crops from 1933-36 inclusive.

Drouths as severe and close together as those of 1934-36 have occurred only once in 80 years. It would be dubious wisdom to carry large stocks for 20 years or more in order to cope with drouths like these, especially since this would involve heroic extrapolation of stabilization base trends in a situation where everything else was unstable. If the years 1934-36 are excluded, stocks of a billion bushels would have been large enough to stabilize corn supplies.

An additional 100 million bushels of corn would take care of the variations in oats production. Feed wheat stabilization, a comparatively small matter, probably should be conducted in the western wheat feeding areas, close to the livestock where the need for it is greatest.

An additional quantity of corn should be stored to meet unforeseen short-time increases in demand. For military preparedness, a billion bushels would not be too much. But that is a military matter. Those stocks should be carried, if at all, on a military budget. We will stick to peacetime requirements here. For this purpose, a relatively small quantity—say two hundred million bushels—may be sufficient.

These minimum reserve stocks might also come in handy for another purpose. The stabilization stocks should not be drawn down to zero, even in a very short crop year, for the next crop may be short too. This happened in 1935 and 1936, after the very short crop of 1934. This is such a rare case, however, that it would hardly justify carrying reserve supplies for that reason alone.

The three items above add up to 1.3 billion bushels. Stocks amounting at their maximum to this figure would be large enough to do a reasonably good job of stabilizing the supplies of feed grains.

Study of Figure 1 shows that the distribution of corn crop sizes is asymmetrical. There is a tendency for several years of moderately good corn crops to come consecutively, followed by one or two severely short crops. Stabilization stocks usually would build up over a period of several years and then be drawn down at one swoop. The stocks frequently would need to be carried for as long as five years at a time. Stocks would have accumulated like this for several years, and then have been used up in one year, over several five-year periods in the past—from 1919 to 1924; from 1925 to 1930; from 1931 to 1936; and from 1942 to 1947.

In the preceding sections, we estimated that quantities of corn ranging from 200 million bushels minimum reserve up to 1,300 million maximum—averaging 750—would need to be carried, sometimes for as much as five years at a time, and frequently for two or three years at a time. The average length of time would be perhaps three years. Thus corn on the average would be carried for about three years, and dumped on the fourth. This would require carrying an average quantity of $750 \times \frac{4}{3} = 562$ million bushels of corn annually.

Before World War II, the estimated cost of storing corn on the farm was about half a cent per bushel per month, or six cents per year. The CCC paid farmers five cents a year for several years, then seven cents. Now it is offering farmers 10 cents per bushel to reseal

their 1948 corn until July 31, 1949, a period of nearly two years. It pays seven cents per bushel for storing wheat.

The CCC only offers to pay storage in certain years when it considers that conditions warrant it. Perhaps the CCC will do this about half the time. This would make the cost to the CCC equivalent to five cents per year.

Large bins like those that the CCC is putting up this year cost from 17 to 29 cents per bushel erected. They should be good for 15 years, with only modest maintenance costs. Thus the annual cost of these large bins would be less than four cents per bushel. Smaller farm-sized bins would cost more, perhaps as much as six cents per bushel.

These costs would be incurred on the entire storage capacity of 1,300 million bushels, whether the bins were full or empty. If about half of the capacity were large CCC bins and the other half were small farm bins, the average annual cost would be about five cents per bushel. That would amount to 65 million dollars. On an average crop of three billion bushels, worth a little more than a dollar a bushel, that would amount to about two percent of the value of the crop.

We saw in the preceding sections that a feed grain stabilization program would increase corn producers' incomes from two to three percent, and reduce hog production costs by a less exactly determinable amount, perhaps also two or three percent. These amounts would add up to about five percent. The storage program would cost about two percent of the value of the corn crop. The total value of hog production in the United States averages about two thirds of the total value of the corn crop. Some reductions also would be made in distribution costs. Ignoring several other qualifications and complications, we can conclude that a feed grain storage program would be worth (to producers in the short run, and to consumers in the long run) several times as much as it would cost.

A Feed Grain Storage Program Could Finance Itself

In a narrow but specific financial sense, a feed grain stabilization program need not cost anything. It could finance itself.

The loan rates for large crops could be set slightly lower than the rate for small crops. This would provide something less than complete stabilization, but complete stabilization appears impractical

anyway. The rise in price from large crop years to small crop years then would cover the costs of storage.

The loan rates for large crops could be set lower than the rate for small crops by setting up, in advance, a schedule of loan rates varying inversely with corn supplies.

A total range of 20 percent—only half the range of 40 percent that is written into the Agricultural Act of 1948—would be more than ample for this purpose.

For other crops, such as cotton, where stabilization of incomes is desirable, the range of 40 percent is not great enough. For these crops, the range should be increased at least to 60 percent.

In any case, the basic loan rate (the rate for an average-weather crop) should be announced early. March would be early enough to help farmers plan the acreage they would plant. But if the rate could be announced several months earlier yet—in November, before farmers breed their sows for the spring pig crop—that would help farmers plan their hog production as well. The final rate for the current crop (as determined by the size of the current crop plus carryover) could be announced shortly before, so as to clear up the final announcement for the current crop before the basic rate for the new crop was announced.

Setting the Basic Loan Rate Each Year

The final problem then would be how to set the basic loan rate for the new crop year.

The principle involved here is clear. The basic rate should be set at the level that would move an average-weather crop on the anticipated acreage into consumption.

The problem is how to put this principle into practice. It is not easy to forecast the strength of the demand from one to two years ahead. Millions of farmers, however, now do it every year as best they can, as individuals; the U.S.D.A. ought to be able to do it better. The more difficult problem is how to resist the political pressure on the U.S.D.A. to set the loan rate high in a futile effort to raise long-time average price levels.

The existing parity formula and the recently proposed modifications of it are not suitable bases for loan rates. Parity is based on the past rather than the future, and it is designed to stabilize prices against variations in demand as well as supply. Loan rates based even on a modernized parity are likely to be too high, reducing con-

sumption and increasing production until storage stocks grow beyond the size needed for stabilization purposes.

Loan rates based on parity could be brought into line with economic realities by writing into the law the provision that whenever the corn storage stocks at the end of the crop year (that is, the carryover October 1) exceeded the quantity needed for stabilization purposes, the basic loan rate for the next crop would be reduced proportionally.⁸

Similarly, at the lower end of the range, if the carryover were less than the minimum quantity needed for stabilization purposes, the basic loan rate for the next crop would be increased proportionally.

Thus if the carryover were 1.43 billion bushels, 10 percent in excess of the 1.3 billion maximum needed for stabilization purposes, the basic loan rate for the next crop (to be harvested a year later) would automatically be reduced 10 percent. At the other extreme, if the carryover were only 70 million bushels, 10 percent (of 1.3 billion) less than the 200 million minimum needed for stabilization purposes, the basic loan rate for the next crop would automatically be increased 10 percent.

This system would be clumsy, slow, and in certain circumstances could be a bit erratic. But it would move the loan program from where it is now toward a more rational system, and do it automatically.

The Program is Basically Physical

Let us now take a little longer look at the future.

In principle, the best way to run the feed grain storage program would be to have no loan rates or loans at all.

A feed grain storage program is essentially a physical program. The purpose of the storage operations is to smooth out the variations in feed grain production, by putting the excess over average-weather production into storage in good crop years and taking it out in poor crop years.

This program need not involve loan or price problems at all. Instead of the loan rates determining how much is put in or taken out of storage, as at present, the program could be handled purely

⁸ A proportional reduction is suggested here only for simplicity and brevity. Perhaps the reduction should be only one-half as great as proportional for the first 10 percent excess of quantity, to throw the loan rate reduction process into gear less suddenly.

as a physical matter; the quantity put in or taken out of storage then would determine the price.

The simplest way to run this sort of a program would be for the U.S.D.A. to remove and later return the proper quantities of feed grains to the market by buying and selling rather than by loans. This would give the U.S.D.A. the most direct and positive control over the storage stocks.

Some practical difficulties would lie in the way of putting these principles into effect.

The first difficulty is a minor one. It is cheaper and more efficient for the U.S.D.A. to make loans on corn in the crib on the farm where it was grown than to buy it and take care of it itself. A buying and selling program would cost more, and get the U.S.D.A. more into the grain business, than the present (primarily) loan program.

The second difficulty is a major one. In the past, the feed grain storage program has been so much an integral part of the whole agricultural price support program that separating the two appeared to be a more drastic operation than the patient would accept or perhaps survive.

A fundamental change may be taking place, however, which would reduce or remove this major difficulty. Secretary Brannan's proposal to let the prices of perishable products seek their own levels and make up the difference between those prices and the "support" levels by direct payments to farmers has been rejected by Congress this year, but the idea may be accepted at some later time. It could be extended to durable products as well as perishable products. No one would worry then about the level of loan rates or open-market prices. The U.S.D.A. then could simply buy and sell feed grains on a physical basis, so as to keep market supplies stable from year to year, untrammelled by any complications about loan rates. Or, if the advantages of loans rather than purchases and sales were considerable, it could use loans as at present, unhampered by upward pressure or unsuitable formulas for loan rates. The upward pressure and the formulas would be applied instead to the "support" prices, not to the loan rates as at present, leaving the storage program free, as it should be, to deal exclusively with the problem of variable feed supplies.

DISCUSSION

ROLAND WELBORN

Swift and Company

Dr. Shepherd has a long and enviable experience in the study of corn prices and their relationship to livestock production and to the agricultural economy generally. He has for years given detailed study to the broad economics of corn storage. It would therefore be somewhat presumptuous on my part to do anything more than to raise certain questions regarding both the philosophy back of his conclusions and the basic evidence from which those conclusions are drawn.

1. So far as I can judge, Dr. Shepherd's calculation of the coefficient of variation of corn production is based on simple historical deviation of production from the long-time trend, including the variations attributable to both the extreme drought of the mid-thirties and the stimulus of two world wars, both of which he rules out as extremities which a storage program should not attempt to anticipate. I would be interested to know how much change would be involved in his concept of normal variation if he measured variation in terms of animal units fed, as he does (which is a more logical measure of availability of feed grains) allowing for trends, but *leaving out of the computations the extremes attributable to droughts and wars.*

2. I must leave to those who are more proficient statisticians than I the task of evaluating the accuracy of Dr. Shepherd's regression of supply on price. I find myself doubting greatly the significance of the calculated two to three percent variation in income from normal vs. variable crops, particularly in view of the fact that the basic data from which those estimates are derived is scarcely accurate within those limits. While such estimates are useful as a basis for price anticipations I would raise the question as to whether they are sufficiently dependable to provide a basis for investing 1.5 billion dollars in an untried economic venture.

3. Dr. Shepherd uses CCC's storage rate as the total cost involved in a corn storage program. These additional refinements may make a significant difference in his cost estimates: (a) there is an interest charge on the investment in corn of at least two or three percent per annum which should appropriately be charged against the program; (b) the same argument that is used to show reduction in the cost of producing pork is applicable in reverse to the cost of storing corn. That is to say, the cost of storage must be calculated as the cost of the facilities necessary to store the largest anticipated volume. If facilities for 1.3 billion bushels of corn storage must be constructed, the cost of those facilities becomes the perpetual cost of a storage program regardless of year to year variation in storage volume; (c) there is a relatively negligible item of administrative cost—minor in this instance, but a persistent part of a broader pattern of costs that in the aggregate has come to absorb a substantial portion of the total national income.

4. The estimated savings as a result of stabilization of pork production presupposes that grain supply stabilization would indeed stabilize pork

output. While the influence of corn supply is a major element in determining hog numbers, it is still appropriate to question how much of the variation still remains after full allowance for feed grain supply variation has been made. It is also an interesting question as to how much variation actually occurs in hog production on farms where any considerable amount of the overhead is specifically assignable to the hog enterprise.

5. I will pass over lightly the question as to whether the level of corn price is likely to be raised or lowered beyond what it would otherwise be by the existence of large stockpiles of corn. In theory, of course, the case is clear. But practice is something else again, and I am personally somewhat fearful that the existence of an average inventory in excess of needs of over 500 million bushel would result in an average corn price to farmers 15 to 20 cents per bushel lower than would otherwise prevail. That consideration is of no significance, of course, if the price is always at the loan rate, but I, for one, hope that there is something better for the future than a perpetual reliance by corn producers upon the United States Department of Agriculture price support program.

6. If Dr. Shepherd's notions of the profitability of such a program is correct, it is interesting to raise the question as to why the private economy has not undertaken it. While I have no proof to offer on the subject, I would like to suggest the following answer: excluding war periods and the mid-thirties drought, there have been only 23 years out of the 69 years since 1880 in which corn price actually increased from year to year by more than 10 percent. I submit to you that as an ordinary business proposition you wouldn't invest much money, even if you were a hog producer, in a scheme that has such a dismal profit record behind it.

All of the foregoing has been debate over quantitative judgments, a debate which can never be totally resolved, although the evidence can be clarified by a continuation of careful technical work. The major questions are those which remain, if I may paraphrase Frank Knight, after the economist has made his contribution, thereby clearing the way for a discussion of the broader issues.

The science of economics (and those who profess it) has a long tradition of argument to the effect that the material well-being of human kind is enhanced by the free play of economic competition. The only basis for the violation of these principles in the public interest is where clear evidence exists of institutional imperfections which prevent the maximization of total income through the exercise of individual initiative. Until more convincing evidence has been presented than I have thus far seen of the failure of private industry to adequately handle the distribution of corn supplies through time, and subject to a more convincing accounting of the gains to the whole economy to be made from monopolistic manipulation of corn supplies and prices, I doubt seriously that the type of institution proposed by Dr. Shepherd would make any material contribution to economic efficiency or to human welfare over the long run.

THE MISSOURI RIVER DEVELOPMENT PROGRAM

HARRY A. STEELE

Bureau of Agricultural Economics

THE purpose of this paper is to outline the major features of the Missouri River Basin development program and to estimate some of the economic magnitudes involved. Other papers to follow will appraise some of the problems.

Next to the Mississippi River drainage system, of which it is a part, the Missouri Basin is the largest basin in the United States. It includes more than a sixth of the land area, about a fourth of the farm land, and a fourth of the cropland of the country. The basin contains about 10 percent of our farm population. Half of its farm population is concentrated in the lower fourth and the remainder is sparsely populated.

The Pick-Sloan Plan

The programs for development of the Missouri Basin represent an evolution of plans by various agencies based on years of experience and investigation. For example, the Corps of Engineers formulated a basin-wide plan in 1943 which expanded the previous flood-control and navigation plans to include additional multiple-purpose reservoirs on the main stem and tributaries of the Missouri River, and flood protection works for municipalities and agricultural lands. In the following year, the Bureau of Reclamation recommended a plan for basin-wide development for irrigation, power and other purposes. These reports were integrated by the two agencies and presented to Congress. In the Flood Control Act of December 22, 1944, Congress approved the coordinated plan, commonly known as the Pick-Sloan plan. Since that time additional proposals have been made. Present plans include about 150 reservoirs with a storage capacity of about 100 million acre feet; levees for protection of two million acres of agricultural lands in the Missouri Valley and major tributaries below Sioux City, Iowa; levees for municipal areas; systems for distribution of irrigation water for new lands totaling five million acres, and supplemental water for another two million acres; hydroelectric plants having an eventual installed capacity of 1,600,000 kilowatts of power and an annual output estimated at 10 billion kilowatt hours of electrical energy;

and improvement of the channel and provisions for navigation from Sioux City to the mouth of the river.¹ Congress has authorized a total amount of \$350,000,000 to be expended by the Corps of Engineers and \$350,000,000 to be expended by the Bureau of Reclamation for partial accomplishment of the program.²

According to the Pick-Sloan plan, the multiple-purpose reservoir projects on the Missouri River will provide for the maximum practicable storage of water on the main stem. The water to be impounded in these, as well as in the other multiple-purpose reservoirs on tributaries, will be utilized for irrigation, navigation, power and other multiple purposes. Sufficient storage will be reserved in each reservoir to provide for flood control needs. To protect towns or municipalities and agricultural areas that are subject to flooding from run-off originating in storms over areas not controlled by the reservoir projects, the plan provides for a system of levees on both banks of the Missouri River from Sioux City, Iowa, to the mouth and the required flood-control works on tributaries. Water will be available for domestic and industrial water supply and pollution abatement, and it is proposed to develop the recreational uses of reservoir areas.³

Shortly after approval of the Pick-Sloan plan for the Missouri River Basin by the Congress, the Missouri Basin Inter-Agency Committee was established to provide a means for the participating federal agencies to coordinate their activities among themselves and with those of the Missouri Basin states. On this committee are five Governors of the Missouri Basin states who were selected by the Governors of the 10 states in the Basin to represent state interest in the Program. On the committee, federal interest is represented by one member each from the Corps of Engineers, War Department, the Federal Power Commission, the Department of Interior, the Department of Agriculture, and the Department of Commerce.

³ Message by the President to the Congress of the United States on the *Comprehensive Plan for the Development of the Mississippi River Drainage System*, July 16, 1947. Appendix 1: Comprehensive Plan for the Missouri River Basin.

The Agricultural Program

Many of the people connected with the Inter-Agency Committee and interested in development of the Missouri River have recognized that the Pick-Sloan program does not provide a complete authorization for resource development because it provides for control and use of water in the main stream channels only. They have urged that an agricultural program be developed to deal with watershed, conservation, and other land-management problems of the basin. At first it was thought that this need could be met under existing national programs. However, it was soon discovered that the agricultural phases of the development were lagging and that it was very difficult to integrate national agricultural programs with other phases of the development which were on a project basis.⁴ In July, 1948, after three years of participation in the Missouri Basin Inter-Agency Committee, the Secretary of Agriculture ordered an agricultural plan to be prepared which would integrate the activities of the Department relating to the development, utilization, and conservation of natural resources into a unified basin-wide program.⁵ The program would be designed to: "Conserve and improve the lands of the basin; build up and protect the forest resource; protect and develop the water resource; enlarge and improve the farm plant by irrigation and drainage; reduce flood and sediment damages, enhance recreation and wildlife; and otherwise support, complement and balance the programs of other agencies—particularly the engineering activities being carried out under the Pick-Sloan plan."

The agricultural program was prepared by a field committee made up of representatives of various bureaus. This group had the active cooperation of representatives of the Land-Grant Colleges and several other state and federal agencies. An inventory of land and water conservation and development needs in the basin was prepared based on past experience and investigation.⁶

The program that has been developed to meet these needs offers no startling innovation in land use or in its approach to the con-

⁴ Opinion in the Department of Agriculture has been divided. One group has favored preparing special basin programs. Another group has felt that such a move would jeopardize existing national programs.

⁵ Secretary of Agriculture Memorandum, No. 1220, July 9, 1948, *Preparation of an Agricultural Plan for the Missouri Basin*.

⁶ *Missouri River Basin Agricultural Program*. U. S. Department of Agriculture, April 1948.

servation problem. The body of the program represents functions and activities which already are under way in some measure in the basin. The unique qualities of the program are: (1) a procedure by which all phases of a complete program of land-management and upstream engineering can be applied to problem areas for conservation and flood control; (2) a procedure for integrating the work of the Department of Agriculture with that of other federal agencies on irrigation, drainage, and other land- and water-development projects, and (3) the recommendation of a greatly accelerated program for the basin which would keep pace with the engineering phases of the Pick-Sloan plan.

The agricultural program has five major operating phases.

1. A program of conservation and improvement measures on grassland and cropland is designed to reach all of the 582,000 farmers and ranchers in the basin. The goal is the application of good land-management and conservation practices to the farm and ranch lands of the basin. This would involve adoption of improved management and land use practices on the 113 million acres of cropland in the basin and the seeding of 20 million acres to grass and legumes for rotation hay and pasture. Needed also would be measures such as 1,900,000 miles of terraces, grassed waterways and others to retain or dispose of water. The privately owned grassland also needs improved management. This includes reseeding of 17,500,000 acres of depleted range, development of water supplies, fire guards, and fences.
2. A program for forest and forest range would cover an estimated 45 million acres, of which 22 million is in public ownership. The forests are a resource with many uses—timber, grazing, recreation and wildlife, and the protection of water supplies. This latter function is of particular importance in federal forests which are the source of a substantial share of the water available for irrigation. The program is designed to improve forests and ranges by applying better management, fire protection, plantings, and many other improvements. On privately owned land the program would be carried out by furnishing technical assistance and financial aid to private owners.
3. A program of stabilizing measures for small watercourses has been proposed to assure safe disposal of water in small watersheds and the lesser tributary streams. This will reinforce land conservation measures, contribute to flood control and to the protection of lands being destroyed by major gullies, bank-cutting, and sedimentation. The program contemplates the construction of measures which generally affect more than one farm. These would include gully-control structures, floodways, bank-protection works, small retarding basins and others.
4. The program for irrigation involves (a) educational, technical, credit, and financial assistance to rehabilitate and improve the use of land

and water on existing irrigation projects, (b) factual data and technical advice in areas for which new irrigation is planned, and (c) assistance and services to farmers in developing land improvements and systems of farming under new irrigation.

5. The drainage program for the Missouri Basin is planned for an estimated 5,800,000 acres now in drainage districts or needing additional drainage. It is estimated that half of this acreage needs some degree of improvement or rehabilitation. The Department will assist farmers in rehabilitating drainage systems and in constructing new systems. It will also help individual farmers with their drainage problems.

These operating phases of the agricultural program are supported by research and investigations, soil surveys and land classification, education and credit.

1. A much accelerated program of soil surveys and land classification is needed to guide the land and water program. The soils of the basin show enormous diversity. Seven types of surveys are recommended to meet the requirements of various parts of the basin. These range from intensive surveys for proposed irrigation projects to extensive surveys in forest and grazing areas.
2. Research and investigations needed to support the recommended programs of land and water development have been designed through the combined efforts of the Department of Agriculture and the Land-Grant Colleges of the Missouri Basin. Accelerated research is recommended to precede and guide the greatly expanded programs of irrigation, drainage, land treatment, and watershed management in prospect.
3. Agricultural extension activities would be intensified to assist rural people to make maximum use of land newly developed for irrigation and protected from floods by levees and drains; to make the best use of electric power; to apply accelerated land conservation and flood-reduction measures and to adjust farming to new crops, new markets, and new methods.
4. Special credit facilities are recommended to supplement private credit agencies in view of the expectation that farmers, ranchers, and landowners will invest three to four dollars for every dollar of Federal funds expended for conservation. Application of conservation measures, and development and improvement of irrigation and drainage systems often require a type of developmental credit that is unavailable from private lenders.
5. Special studies are recommended to assure that the rural electrification systems for the basin will be completed and integrated with the power features of the Pick-Sloan plan. Continuation of present authorizations will provide ample loan funds to complete electrification of the area.

The agricultural program was submitted to the Missouri Basin

Inter-Agency Committee at Rapid City, South Dakota. The Committee meeting at Helena, Montana, July 21, 1949, passed a motion that the "Inter-Agency Committee thank the Department of Agriculture for preparing the report, endorse the general objectives and recommend that Congress take the necessary steps to put the program into effect."⁷ As soon as review by other federal agencies has been completed, the report will go to Congress.

Cost of Missouri Basin Development

The cost to the Federal and State Governments of the Missouri Basin Development has been currently estimated as follows:

Corps of Engineers ⁸	\$2,019,000,000
Department of Interior ⁹	3,024,000,000
Department of Agriculture ⁹	3,092,000,000
Other Federal (6 years) ⁹	20,000,000
State Government (6 years) ⁹	100,000,000
	<hr/>
	\$8,255,000,000

The development period is usually thought of as extending over a long period of years. If 30 years is used as in the agricultural program, the annual rate of expenditures would be about \$275,000,000 for federal funds. In the fiscal year 1949 the Corps of Engineers received \$92 million for the basin, and the Department of the Interior, \$87 million, or a total of \$179 million. The Department of Agriculture made expenditures for the type of work covered in its program from its regular or national funds of about \$24 million in the Missouri Basin, but received no special appropriation in 1949 for this area. From these rough calculations it can be seen that a considerable acceleration of the agricultural program is needed to put it on a schedule that will be comparable to the other phases.

Land Use Changes

It is not the purpose here to attempt a benefit-cost analysis. However, part of my assignment was to estimate the agricultural changes from the Basin development. These might be summarized as follows:

⁷ Minutes of the Thirty-Second Meeting of the Missouri Basin Inter-Agency Committee, July 21, 1949.

⁸ Missouri Basin Inter-Agency Committee, *6-Year Program for Missouri River Basin*, July 29, 1948.

⁹ U. S. Department of Agriculture, *Missouri River Basin Agricultural Program*, April, 1949.

Two million acres would be given protection from floods.

Five million acres now dry-farmed would be brought under irrigation.

Two million acres now irrigated would be furnished supplemental water.

One million acres of small irrigation would be developed.

Three million acres would be benefited by new or improved drainage facilities.

Ten million acres of cropland would be returned to grass.

Another ten million acres would be shifted from soil-depleting crops to rotation hay and pasture.

A land management and conservation program would be applied to all lands.

Two and one-half million acres are included in reservoir sites.

Of this, one million would be flooded only occasionally and could be continued in agricultural use.

Data on expected production changes are rather meager. Such estimates as are available indicate, for example, about a 10-percent increase in value of crop production from irrigation in the Missouri Basin and about a 19-percent increase in crop production from the conservation program. A small loss from reservoirs would amount to less than one percent.¹⁰ The net increase in production from these sources would be about 28 percent when compared to crop production in the basin and four percent when compared to national production. Other changes in production would occur because of flood protection and drainage, range management, timber production, etc. These changes would take place gradually over a long period of years.

¹⁰ Bureau of Agricultural Economics unpublished estimates based on data from the Bureau of Reclamation, Corps of Engineers, and the Soil Conservation Service. Comparisons are based on 1939-44 prices.

AN ECONOMIST'S APPRAISAL OF THE MISSOURI RIVER DEVELOPMENT PROGRAM

R. R. RENNE
Montana State College

THE magnitude of the Missouri River Valley in physical area and the variety and complexity of its resource use problems are such as to cause proposed resource development programs for the area to have general appeal and interest throughout the nation. In appraising the proposed developments which have been presented in the preceding paper it would be wise for us to keep two things in mind: (1) the great importance of agriculture in the Basin; (2) the strategic role of water.

The Missouri River Basin is primarily agricultural and promises to remain so for a great many years. Therefore, any sound or complete development program must, of necessity, include a sound agricultural development program including land management and soil conservation, and give primary emphasis to all aspects of the overall program which will improve and help stabilize the farm and ranch operations of the Basin.

In the upper Missouri Basin states, normal rainfall is relatively low and extremely variable with recurring droughts. In this semi-arid part of the Basin, the conservation of water through sound watershed management, storage and wise use, is of primary importance; while in the lower part of the Basin a humid climate exists and flood damage is considerable. Because of these conditions maximum economic development and use of water in the Basin is a key to maximum human welfare in the area. Control and use of water in the main stream channels through big construction projects is only a part of an adequate water use program. Sound land management and cropping practices to control run-off, sound forest and range management practices to achieve maximum water-holding capacities, and stabilization of water courses to reinforce land use practices in order to hold water on the land and ease it to the main stream channels without flood or overflow damage, are all highly significant parts of a complete water use program along with large dams or construction projects.

Agricultural Development Program

Unwise management of land and poor land and cropping prac-

tices are common throughout the Missouri Basin. This in itself does not justify an extensive agricultural program of the nature proposed, however, because similar conditions exist in other river basins of the country. What justification is there for a special agricultural development program for the Missouri Basin? Is this a mere starting point for similar programs to be proposed and urged for other river basins in the nation? Or is the need in the Missouri Basin for such a program particularly acute and timely?

The Flood Control Act of 1944 places irrigation in the front rank of priority uses of water in the West. The Pick-Sloan Plan, developed by the Corps of Engineers and the U. S. Bureau of Reclamation, proposing construction of some 150 large reservoirs and for which Congress has already authorized a total of 700 million dollars, makes a complete agricultural program essential. The scope of the Pick-Sloan Plan is such that unless other programs are designed and carried out for the area which will make available the information necessary for sound overall development, a great waste of public funds as well as incomplete and unsound development may result. Moreover, the uncertain growing conditions in the upper Missouri states because of the semi-arid climate make it imperative that this large agricultural area of the nation be developed in such a way as to stabilize its production and contributions to the national welfare as quickly and as completely as possible. Large public expenditures for relief and feed and seed loans in the Upper Basin states were necessary in past years when adverse weather and business conditions and severe insect pest ravages occurred. Development programs that will help stabilize farming and ranching operations in these states will relieve the government of future relief and emergency expenditures. More important, sound agricultural development programs will permit the Missouri Valley with its great grain and meat production capacities to make its maximum contribution to the national welfare. We should not forget that one-fourth of the nation's farmland lies in the Missouri Basin. Farm output in the Basin during the past decade under favorable weather conditions has been a very significant factor in making it possible for us to improve our level of living at home at the same time that we carried out a major war and its attendant post-war reconstruction and rehabilitation programs.

The question immediately arises as to whether an agricultural

development program such as that which has been explained in the preceding paper should precede a major engineering or construction program such as the Pick-Sloan Plan, or whether it should be carried out concurrently with such a program, or whether it should follow the construction program. The facts are, of course, that the large engineering and dam construction program is already under way while the detailed agricultural development program is merely in the proposal stage. Some contend that construction planned in the Pick-Sloan program will not only needlessly flood hundreds of thousands of acres of land but will create huge silt traps, without at the same time checking serious flood water damage in the small water courses and farming areas generally. To carry out the agricultural program concurrently with the dam construction program may result in our discovering that the basically sound agricultural program will leave us with many large reservoirs which will never operate as now planned. Hence some suggest that the research and educational phases of the agricultural development program together with the land management phases should be pushed rapidly now, before any further work is done in the construction of large dams as contemplated by the Pick-Sloan Plan. The Department's agricultural program as presented indicates that what might normally be undertaken over a one hundred-year period has been telescoped into a thirty-year project proposal, but perhaps it should be telescoped still further into a fifteen- or twenty-year proposition, particularly since much of the information and resulting developments are essential for a future sound system of major dams in the Valley.

This should not be interpreted to mean that agricultural development as proposed in the five-point program should be complete in 15 to 20 years. As a matter of fact, full agricultural development will probably never be complete. The educational and research phases of the program, however, need to be greatly speeded up. The next five to 10 years should reflect tremendous expansion along these lines.

Is the Missouri Development Program Needed?

Currently we are faced with the threat of great surpluses in several farm products including wheat, one of the major products of the Missouri Basin. Acreage limitations are being worked out to reduce wheat acreage. Under these conditions, what economic

justification is there for undertaking the five-point agricultural development program proposed? It is said that the development program will ultimately result in increasing the irrigated farm land of the Basin two and a half times from the present five million acres to some 12,500,000 acres. This more than doubling of present irrigated acreage would mean a great increase in the agricultural production of the Missouri Basin, but it is estimated it would increase the total farm production of the United States by only a small amount. For example, the increased irrigated acreage contemplated under the Pick-Sloan Plan would result in a 70 percent increase in the crop output in the Upper Missouri Basin states, and a 40 percent increase in crop output for the entire Basin, but would result in an increase of only about five percent in the total United States crop output.

Part one of the five-point agricultural development program, "Conservation and Improvement Measures on Grasslands and Croplands," is designed to achieve good land management and conservation practices on all the 582,000 farms and ranches of the Basin. More than a third of the approximate three billion dollars proposed for the agricultural development program (\$1,189,630,000) is proposed to be spent on Part One. Certainly this part of the program should result in increasing the farm output of the Basin as well as to make the output more certain, consistent or stable year in and year out. The prospective increase in the country's population for the next thirty years does not seem sufficient in and of itself to warrant any large increase in farm production. Present prospects for large exports of farm products at profitable prices also do not appear bright. But, if the management and conservation practices result in increased livestock and meat production through better forage, hay and feed production, rather than increased cash grain farming, the Basin agricultural development program should fit in well with national needs for the next few decades.

The major objective of increased irrigated acreage in the Missouri Basin through large dam construction should be the stabilization of existing agricultural operations, primarily the range livestock industry through the production of more hay and feed supplies. It is generally agreed that increased numbers of livestock will be needed in the United States to maintain a satisfactory standard of living, particularly in view of prospective population increase during the next thirty years. The stabilization of the

livestock industry in the Missouri Basin can best be brought about by integration of irrigated lands with the surrounding dry bench lands and grazing areas. Development of additional irrigated farms for the production of cash crops will not contribute to the welfare of the Basin population or to the national welfare as much as will a program in which the newly irrigated lands are primarily used to stabilize operation of existing dry farm and ranch units. If ways can be worked out whereby the new irrigated acreages can be made a part of existing units and used primarily for the production of hay and feed supplies, maximum beneficial production and the most satisfactory and stabilized agriculture for the Basin can be achieved. For example, if a limited acreage, say 40 or 80 acres, of irrigated land could be made available for the individual operator where he could have his home and his operating headquarters, he could, in addition to having a satisfactory garden, produce adequate hay and feed supplies for his livestock. He might also have allotments in grazing districts for summer range of his beef cattle and produce grain on near by benchlands. If, on the other hand, newly developed irrigated areas are developed to be complete operating units alone, and are used primarily for the production of cash crops, such as wheat, beans, etc., the lands will not contribute to the further stabilization of output of existing farm and ranch units. There is no assurance in programs already under way or being proposed that such integrated use of irrigated lands will be achieved. Much good thinking and administrative action is needed along these lines now.

When one ponders the scope of some of the proposed developments, he is likely to conclude that it is some bureaucrat's idle day-dreaming. For instance, 500,000 new ponds seems like an excessive number, but the Missouri Basin covers a large area and anyone who has traversed the Plains knows it is "big" in every sense of the word. The proposed 14,000 to 16,000 small upstream dams and 400 to 600 desilting and debris basins may sound excessive, but careful study of the many small streams and water courses of the Basin will show that the number may be an underestimate, rather than the reverse. The one billion dollars proposed for this phase of development is absolutely essential if we are to get value received from the five billion dollars proposed to be spent by the Corps of Engineers and the Bureau of Reclamation in constructing 150 large dams or reservoirs.

Experience with heavy silting of large reservoirs already con-

structed in the West should emphasize that Point 3 of the five-point agricultural development program, "Stabilization of Small Watercourses," is not competitive with the Pick-Sloan large reservoir construction program, but complementary and absolutely essential for its successful operation. Point 1, "Conservation and Improvement Measures on Grasslands and Croplands," including terracing, grassing of waterways, reseeding depleted ranges, strip cropping, and contour farming is likewise basic and complementary. It would appear that the tentative allocation of two-thirds of the total of three billion dollars proposed to be spent on the agricultural development program for these two phases is justified.

Conclusions

Although the agricultural development phase of the Missouri Development Program does not have the dramatic or glamour appeal to the public imagination of the big reservoir construction phase, it nevertheless, over the long pull, promises equal if not greater advantages to the Basin and to the Nation. The estimated total cost of somewhat over eight billion dollars for the entire program is a large sum, but in terms of modern federal fiscal accounts does not loom as excessive. Before we can be certain that this eight billion dollars will be a good investment much sound thinking must be done on other phases of overall development in the Basin comparable with that which has been done by the Department of Agriculture staff members, in developing the proposed Missouri River Basin agricultural program. Reference is made to power development and utilization, including rural electrification and industrialization, and to navigation. These two enterprises are emphasized in the large dams construction phase of Missouri Basin development along with irrigation and flood control, but much heat and little light has resulted from the discussions of these two enterprises to date. There are many phases of public power development which need to be studied and an adequate program mapped out, but the navigation aspects particularly should be subject to very careful scrutiny from the standpoint of possible economic benefits before any further steps are taken to allocate water for this use in achieving a "9-foot channel," etc. Water is a very precious thing in the Upper Missouri Basin, and while the agricultural development program, if adequately carried out, would go a long way to conserve and make possible maximum avail-

ability of water in the Upper Basin, it will be of little local or national avail if the resulting water is not put to its most important and best uses. Whether navigation can qualify as a claimant in this category has certainly not been established on any sound basis. It would seem that in the long run, Basin, national and world interests would dictate that wise conservation and utilization of water for stable and maximum production of food and fiber would be a "better" use of such waters, if not the "best."

This writer concludes that the proposed eight-billion-dollar expenditure in the Missouri Basin can be a very good investment for the nation in the years ahead. Because they lack the glamour and appeal to the public imagination which some other phases of the program possess, there is grave danger that the agricultural phase and similar detailed information and proposals needed on other phases of the overall program will be sidetracked or carried out inadequately. They are basic, however, to a sound over-all development program and should take a position of priority rather than a second- or third-rank position.

For the next few years it would seem highly desirable to emphasize the five-point agricultural program and to speed up work particularly on the educational and research aspects, especially soil surveys and land management, before we proceed too far with construction of large dams and reservoirs. The agricultural development program is essentially a grassroots program. To be fully effective it will require adequate support for its educational and research phases. If such support is forthcoming and the Land-Grant Colleges and Universities' staffs are equal to the challenge, a long step will have been taken toward assurance of sound overall development of the Missouri Basin for the years to come. Complete development will take many, many years, but it's high time that we put first things first in the Missouri Basin. The proposed agricultural development program presents an important challenge to Land-Grant institutions, particularly to agricultural departments, and more especially to departments of agricultural economics and rural sociology.

A CONSERVATIONIST'S APPRAISAL OF THE MISSOURI DEVELOPMENT PROGRAM

T. L. GASTON
Soil Conservation Service

THE Missouri Basin includes about one-sixth of the land area, one-fourth the farm land and one-fourth the cropland of our United States. The Basin is, of course, paramount to the people who inhabit it and the agricultural significance, together with the industrial and other parts of our economy within its boundaries, makes the Basin of no little importance to the nation.

During the last three or four decades we have stepped up the development tempo within the Basin—at least the part involving direct exertion of the public's efforts. A number of lines of public endeavors were initiated during the 'teens and 'twenties. Some of these were federal activities involving application of a nation-wide program either throughout or within a specific portion of the Basin. Some were endeavors by states or through local government—as counties, municipalities, irrigation districts, drainage districts and the like. In the thirties, partly because of the depression and the drought—which was particularly severe in a large portion of the Basin—certain going public activities were re-emphasized and additional ones were initiated. Several of these stressed either new or increased emphasis upon conservation, use and development of agricultural land and water resources.

From the conservation viewpoint among the most significant of these new endeavors and results perhaps were:

1. Programs for the public providing technical services and grants of direct aid for conservation purposes;
2. Beginning of soil conservation districts as local governmental subdivisions through which landowners and operators, when they so choose, can cooperatively exercise their own initiative and responsibility for soil and water conservation purposes and obtain help from all public and private sources in so doing;
3. Increased attention to irrigation in parts of the Basin and to proper drainage in others;
4. The growing knowledge on the part of landowners and operators and the public generally that the nation's land and water resources are not limitless but that these resources could be

used to maximize productive capacity on both a current and a sustained basis and, if need be, on a reserve basis.

In 1944, we added the Pick-Sloan Plan for the Basin. This plan deals primarily with major structures along the mainstem and the large tributaries, such as large dams storing water for power production, for irrigation, and for flood control and navigation; levees and revetments for flood control; and major canals and ditches for distributing irrigation water or for draining off excess water. This plan¹ apparently serves the same general functional purposes as the declaration of policy in the most frequent type of legislative authorizing act.

And in 1949, we have the Missouri River Agricultural Program.² Since Congress has taken no action, it is still in the embryonic stage insofar as legislative action is concerned. This plan deals with two categories of activities: first the practices, measures and land uses which when adopted on the land and small tributaries conserve the land and water, and retard and reduce runoff thereby reducing floodwater and sediment damages; and secondly, activities that facilitate programs leading towards adoption of such practices, measures and land uses. The "on-site" and "off-site" effects of such of these practices, measures and land uses, as are soundly applied in the locations where they are adapted, bear both directly and indirectly on the works described in the Pick-Sloan Plan. Thus, the work described in each of the two plans is intended to be supplementary and complementary to the work described in the other. When once the work gets into gear there would be no twilight zone between the necessary large engineering works along the mainstems and the necessary work on the watershed lands and small tributaries.

In view of the setting, a conservationist's appraisal of the Missouri River Development program probably should include considerations of the need and major approaches and problems.

Cursory examination by the close observer points quickly to the need for further conservation in the Missouri Basin. Examination of available research results and survey reports shows even more vividly the necessity for this work. There can be little question but

¹ Public Law 534—78th Congress.

² The Missouri River Basin Agricultural Program, a program recommended by the Secretary of Agriculture Charles F. Brannan for the development and conservation of land, water, and forest resources, and for flood control in the Missouri River Basin, USDA, April, 1949.

that further conservation and development will be accomplished within the Basin. Also, there can be little doubt but that further conservation and development is practicable from the separate or combined viewpoint of individuals, local governmental subdivisions, the states, and the nation. The many questions as to what, how, and when will only be answered month by month, year by year, and decade by decade as progress is made—but then not to the satisfaction of all. The estimates on quantity of work needed as shown in either the Pick-Sloan or in the Agricultural Plan developed by the Department of Agriculture will undoubtedly be subsequently proven less than completely correct. But the main consideration is that the types of work described need to be done. Surely methods and approaches will be improved from job to job as the work progresses, experience is gained and additional research conclusions become available.

Each type of work described in the five operational programs and in the five facilitating programs of the agricultural plan are now being carried on—to varying degrees—under one or more legislative authorities. If the objectives are to be attained in the time estimated—30 years—the problem becomes one of accelerating the various types of work in proper timing and sequence. To do this will require both careful timing in the availability of the required public funds and adeptness in using those that become available.

Too, it seems likely that in the computations back of the various estimates, the proportion of the total cost the public should bear has been overemphasized. Broadly speaking, for the work that really needs to be done, surely the public should bear the proportion of the cost inputs that represent “off-site” benefits. And landowners and operators should bear the costs for “on-site” benefits. There are numerous indications that the “on-site” benefits are greater than are generally recognized. If approached with reason and practical recommendations, the landowners and operators will apply and maintain a larger proportion of the needed work than if they are otherwise approached. The proportion of costs currently estimated as the public’s share can probably be lessened as the measures and practices are applied.

The public is composed of *all* individuals and interests. It carries on its endeavors through units of government. The people, through their state, county, municipal and other local governments, stand to benefit from the proposed work being performed. Units of

government other than the federal should, therefore, proportionately share in the work that is done. It is entirely probable that current estimates have under-emphasized what should rightfully be done by the members of the partnership represented by units of government other than federal.

The old axiom relating to the whole and its parts is equally applicable to the Basin. Sound conservation analysis and action for a region of this size and complexity must encompass several physical areas of progressive inter-dependencies.

1. The watershed.
2. A sub-watershed (or major tributary).
3. A minor watershed (or minor tributary).
4. The very small watershed including a few such tracts.
5. The individual tract of land—farm, ranch, road right-of-way, etc.

The predictable effect of some measures may be nearly all "on-site," the effect of others may be partly "on-site" and partly "off-site." And still others may be entirely "off-site" or downstream from their location. While the agricultural plan, of course, failed to describe all the problems and solutions in realistically clear perspective, there is a tone of interdependence between the work and activities recommended that is somewhat uncommon. Hence, to the degree that the plan is carried out, it will be useful as a guide to facilitate integration of the various activities and types of work.

Considerable progress has been already made in getting conservation on the land. Close to 400 soil conservation districts have been organized covering about two-thirds of the Basin. Thus far, these districts have helped farmers and ranchers bring under conservation management around 40 million acres. Of these, about 25 million acres have been completely treated with a good conservation program safeguarding the productive capacity of the land and increasing the efficiency of farm and ranch production. And, about 600 thousand of these acres represent intensive irrigation and drainage practices. The remainder involves practices and measures for conservation of soil and water, proper management of soil, crops, range, woodlands and includes also the conversion of approximately $1\frac{1}{2}$ million acres from crops to grass or other permanent cover.

The formation of these districts has taken place during the last twelve years. Their accomplishments in large part have occurred

during the last five years, and progress of the movement can be said to be most encouraging.

While the type of work just mentioned has considerable "off-site" benefit its primary effectiveness is on the land where it is done. The other phase of upstream conservation—with the objective of retarding runoff, of increasing infiltration, of stabilizing small water courses, and reducing sediment damage on land and in reservoirs, and of other downstream values—has just begun. Historians are likely to say that the '30's and '40's were a period during which we went through the mental throes of understanding this concept and developing ways and means for doing something about it. (By way of parenthesis I add, many of you will recall that only about two decades ago did we begin to really try to do something about the conservation of the nation's land—especially the privately held farm and ranch land. Now, conservation is generally accepted and the common statement is that accomplishments need to be speeded up.)

At present, this second phase of conservation work is being carried on in the Basin with particular emphasis only on the Little Sioux Watershed consisting of some 4000 square miles in Iowa and Minnesota. Work is underway in 17 of its sub-watersheds. Both phases of conservation work are being done as an integrated job. Conservation treatment and use of the land, and small flood-water retarding structures, measures for the control of headcutting gullies, and other measures for stabilizing small watercourses all become integral parts of a single job. Twelve soil conservation districts are taking part in this undertaking. The district commissioners—as district governing body members are designated in Iowa—have organized themselves into a watershed working committee to determine priority of sub-watersheds and to properly relate the work in each sub-watershed to the work in the others.

It takes time for farmers and ranchers to understand their land and water problems, to organize themselves, and to make the decisions they need to make in order to move the work along in an orderly fashion. In developing approaches for attaining conservation and development objectives in the Basin we must not overlook our cherished system of private land titles under which is held, in fee simple titles, a large proportion of the agricultural land, including range and woodland. Those holding title may be intensely interested, or have no interest in the success of their tract. They

may live on the farm, or in a nearby town, or thousands of miles away. Soil, slope, topography and climate vary from one section of the Basin to another and from farm to farm or ranch to ranch. The desires, aptitudes, likes and dislikes of individual farmers and ranchers also vary from unit to unit. And so it is that the conservation and land use practices applicable on one farm in the upper part of the Basin are not likely to be either practical or effective in the lower part—or perhaps even on an adjoining tract. The conservation practices and land uses must fit the land and at the same time suit its owners and operators.

The meanings symbolized by the first three words of the Constitution of our Nation, "We the people . . ." are at work and are bringing about the conservation and development of the Basin. The problems confronted are many and complex. Progress is rapid but the job is big. Attainment of objectives will require many years.

AN ENGINEER'S APPRAISAL OF THE MISSOURI BASIN DEVELOPMENT PROGRAM

JOHN A. SHORT

Missouri Division of Resources and Development

IN CONSIDERING the Missouri Basin Development Program from an engineering aspect, it seems almost impossible not to touch upon certain other aspects such as economic, political, and social considerations. Engineering considerations must always take into account various other influences. Any good engineer will recognize these influences and temper his engineering decisions to some degree in accordance with those outside influences. However, these outside influences should never be allowed to predominate to the point where good engineering becomes secondary.

The Missouri Basin Program is certainly of national importance in many ways. The economy of the area will always be a vital factor in the economy of the nation. The bulk of the expenditures being made for development come from the federal government, yet has any economic analysis of the program, from a national point of view, ever been made? Is it desirable to carry on the program at such an accelerated pace during this particular national economic level? Do we need increased production, in some cases costing hundreds of dollars per acre, at this particular time when we find it necessary to have price supports on farm products at a high level?

Soil erosion is depleting the productive capacity of the Basin at a rather alarming rate. In order to maintain and increase the productive capacity, it seems logical that soil conservation measures should occupy a high priority in any development program for the Basin. Strange to say, this matter has received serious consideration only in recent months and very little work has been done to accelerate the program of soil conservation. On the other hand, irrigable land represents a potential productive capacity that does not deteriorate when not in use and can be brought into use at the proper time to bolster national production when it is most needed.

It seems that the first requirement for the Missouri River Basin is to enhance the economy of the region to the point where it becomes a national asset rather than a national liability. I seriously question whether the development program, as it is now being carried out, will of itself accomplish this. I see very little attention being given to industrial development. Industry is certainly one

important factor in developing the potential economy of the Basin. Power produced from the development program may constitute some inducement to industry but of far greater importance are transportation costs, markets, capital, labor, and industrial know-how. I see nothing in the present program that gives serious consideration to any of these factors. There are many other resources such as minerals and forests which are not receiving the attention they should in the program.

One must conclude that, from an engineering standpoint, the planning and execution of the Missouri Basin Program is almost entirely backward. The reasons for this are many in number and varied in character. In the first place, this nation continues to grope blindly for want of a suitable comprehensive national policy with respect to resources development. Hence, as a nation, we are totally unprepared to squarely face a problem of the magnitude of the Missouri Basin Program. The engineering features contained in the Program were planned by various agencies which by law are restricted to narrow objectives. The Program was authorized by Congress hastily as the result of a wave of hysteria resulting from the floods of 1943 and 1944 and of the rising tide of sentiment for a Missouri Valley authority. It is true that the projects authorized had been under consideration and analysis for a number of years, but always with limited objectives in mind.

The first logical step in planning a River Basin Development Program is to take an inventory of the resources and problems and then list them in the order of their relative importance. Planning should then proceed as nearly in accordance with this listing as practicable. This has not been done to date in the Missouri River Basin.

Engineering for the Missouri River Basin Development may be divided into four phases. The first phase is the engineering planning. The second phase is the design of engineering structures. The third phase is the construction and the fourth and last phase is the operation of the completed structures. A large part of the planning has been done although I expect some of it may have to be redone. Considerable design of specific structures has been accomplished and we are in the process of carrying on the construction at a rather high rate. Operational problems to date have not been encountered in major proportions, but they will surely come. In my opinion, the planning phase is the most important of all the engineering

tasks presented. I think, perhaps, this has been the weakest of all the engineering work.

Engineering design has become a rather set mathematical science. Construction under American engineering direction is something that the whole nation can well be proud of. Operation becomes a matter of making the most of the physical conditions at hand. Operations problems can become extremely difficult if the planning and designing phases have not been properly carried out. For instance, if a flood control reservoir has not been properly planned for use with other reservoirs in a system or if the design capacity is insufficient, certainly operation of that reservoir becomes an extremely difficult matter. If irrigation storage is not properly placed, or is inadequate because of insufficient data on available water, the operating engineer again takes a beating. Certainly, if irrigation storage is constructed without a thorough knowledge of the soil to be irrigated, considerable difficulty may be encountered. Likewise, if drainage problems are ignored on land to be protected by flood control reservoirs, or a system of reservoirs, release from the reservoir may well cause trouble. If a stream flows from three-fourths to bank full for a long period of time as a result of release from a flood control reservoir, or a system of reservoirs, the land adjacent to the stream cannot be properly drained and crops will die just as surely as if they had been covered for a lesser period of time by flood water. I am firmly convinced that some of the land which is now considered to be irrigable and on the basis of which irrigation storage is being considered, may later prove to be unsuitable for irrigation. I am also convinced that insufficient attention has been given to land drainage in general and especially on land below flood control reservoirs.

Some \$350,000,000 has been spent on the Missouri River under the name of river navigation. Yet, to date, there is no appreciable navigation on the river—certainly no amount commensurate with the expenditure of funds that have been made during the last twenty years. I am "from Missouri" on the question of navigation on the Missouri River. I think it would be a fine thing if it would develop to the point where it would completely pay its way. I question whether this point will be reached and I question the engineering feasibility of producing a navigable channel that will encourage the use necessary to offset the cost. I especially question the open-channel methods now in use.

From strictly an engineering point of view, the present laws pertaining to power distribution are not satisfactory. The shortest possible transmission distance from the point of power production to the point of consumption is the situation which the engineer likes to see. Distribution losses can thereby be kept to a minimum and the maximum amount of power reaches the consumer. Under existing law, public bodies such as municipal distributing bodies and power cooperatives receive first priority in the purchase of federally produced power. Hence, in order to reach these public bodies, longer transmission distances than would otherwise be necessary will frequently be encountered. I further question the adequacy of these laws from a political and social standpoint.

I am amazed at the popular misconception as to what the Missouri Basin development program will accomplish. There appears to be a feeling that a huge expenditure of Federal money in the Basin will automatically insure prosperity regardless of how the money is spent. Some people pretend to believe that the program will eliminate droughts, floods, blizzards, and grasshoppers. People of high standing have been led to believe that construction of reservoirs in the upper part of the Basin will almost entirely eliminate floods in the lower river. They consider that the upper states are making considerable sacrifice for states in the lower part of the Basin. As a matter of fact, if all the reservoirs planned outside of Missouri and Kansas were constructed, the people in the lower part of the Basin would find it difficult to notice any difference in floods. I say this in spite of the large flood reductions that have been accredited to the Fort Peck Reservoir. Any honest engineer who knows anything about the hydraulic characteristics of floods would not claim that a given reduction of peak flow at a certain reservoir site would carry undiminished for hundreds of miles downstream.

There is widespread misunderstanding as to what a soil conservation and improved land management program in the Basin can accomplish. The major physical benefit from a good land management program accrues to the land on which the program is placed and not from any off-site benefits. I wish to repeat that statement. The major physical benefit from a good land management program accrues to the land on which the program is placed and not from any off-site benefits. If there were a hundred percent participation in an optimum land management program throughout the Basin, the effect on floods in the lower main stem of the Missouri River

and its major tributaries would be so small as to not be measurable. There are technical computations and results of research which will verify this but which I do not have time to elaborate on here. Please do not get the impression that I am opposed to such a program. I strongly recommend that an improved land use program be initiated, or perhaps I should say accelerated at the earliest possible date. I urge this because of the great benefit such a program would be to the land on which it is placed and not primarily for any off-site benefits it would bestow.

Some experts, in their enthusiasm for "holding the water where it falls," may run head-on into state water laws in the upper states of the Basin. Some of the water they expect to trap and use where it falls may already be allocated by law to downstream users.

The destructive effect of silt on some of the large reservoirs planned and under construction should not be minimized. However, I find that the seriousness of this problem is frequently very much exaggerated. As far as possible, soil should be retained in its original position on the land. Beyond this point, it is frequently more economical from every point of view to trap it in large reservoirs than it is to install costly supplemental works to keep it out of the reservoirs.

Perhaps this paper has been pointed too much toward criticism of the Missouri Basin Development Program without much of a constructive nature. However, the magnitude and economic implications of the program seem to call for all the honest and straightforward thinking of everyone. I feel that we have not done enough of this. The Missouri River Basin Program, if properly planned and executed, can be of tremendous benefit to the national economy. The mere expenditure of federal money will not insure its success. Unless the states and the people of the Basin recognize and assume their responsibilities rather than depend entirely on the federal government, the program will be a miserable and costly failure. The economy of a region depends on the resources of that region and how fully and wisely the people use those resources. Government can provide some stimuli and assistance, but beyond certain limits, it is ineffective. It is ultimately up to the people of the Basin to "carry the ball."

NEW DIRECTIONS FOR LAND ECONOMICS RESEARCH: WEST

M. M. KELSO
*Montana State College**

TWO related but dissimilar approaches to this discussion are available. One—the more usual—rests on advancing a formal definition of land economics in order to distinguish it from other fields of the parent discipline “economics” and to follow this definition by a break-down of land economics into sub-fields with a listing of research needs under each sub-field. In such an approach, fine-spun distinctions with hazy boundaries are common and terms such as “land utilization,” “land classification,” “land settlement” and the like, the content and meaning of which are nebulous and more conducive to argument than to agreement among research workers, will be found liberally sprinkled through the discourse.

The other approach—the one I will follow—starts with the common sense knowledge that there are distressing economic problems in our western society that have their roots in the peculiar structure of the western natural environment and in the institutions man has erected in the West for guiding his behavior in the utilization of that environment. The focus in this approach is on *problems* thus rooted in the “land” and in “landed” institutions. Whether all of them are problems that fall clearly within the logical categories that might be advanced in the first approach is totally unimportant. The problems are there; they must be tackled by somebody interested, trained and experienced in their analysis. Whether such investigations are entered into by organizational units carrying “land economics” in their title or by specialists dubbed “land economists” is solely an administrative question private to each research organization. The crucial matter is to recognize the existence of the problems that may be called “land economic” problems and to assign men of appropriate qualifications to their investigation.

The discussion that follows will be concerned with land economic *problems* peculiar to the western United States. They are problems that warrant consideration under the heading “land economic research” only because they have a common source in the peculiar

* Contribution from Montana State College, Agricultural Experiment Station. Paper No. 220 Journal Series.

structure of the western natural environment or in the institutions man has erected in the West for directing his behavior in the utilization of that environment.

Problems Rooted in the Structure of the Environment

The physical environment of the West exhibits peculiarities of great economic consequence. Much of the land economics research in the West must, if it is to come to grips with the crucial facts of the environment, be directed to such problems as these environmental peculiarities create. They will be discussed here in three categories: (1) Those problems that grow out of a fluctuating, semi-arid climate; (2) those that grow out of the peculiar inter-relatedness in production of resources located at widely separated geographic points; (3) those created by the peculiar importance of "multiple-use" of much western land.

The economic consequences of a fluctuating semi-arid climate. If the question were asked, "What single environmental condition is most characteristic of the western United States?" probably most persons would reply, "aridity" and some would add the adjective "fluctuating." Yet much of our research into the economics of resource utilization rests on "soil surveys" or on "soil and slope" classifications. Rarely, except as to areas distinguished by the amount of rainfall, do we relate our research to crucial climatic differences.

Frequently of greater importance than soil type or slope and always of at least equal importance in the triumvirate of soil, slope and climate, are such factors of the climatic environment as amount, seasonality, time, intensity, and variability of rainfall; humidity and evaporation rates; and levels and variability of thermal energy. Admittedly the shortcomings in our economic research related to climatic factors are due in part to shortcomings in the basic physical data. Probably we economists should prod the natural scientists into giving us better basic climatic data. But in the meantime we should undertake research into the economic significance of climatic phenomena. We should not hesitate to get into analyses of basic climatic data ourselves. The work begun by Dr. Marion Clawson in the variability sequences of rainfall in the West¹ should

¹ Clawson, Marion, "Sequence in Variation of Annual Precipitation in the Western United States," *Journal of Land and Public Utility Economics*: August 1947, pp. 271-287.

be carried further and greatly broadened to embrace other climatic factors, and the economic significance of the variability patterns developed should be explored.

We need to do a great deal more research on climate and the delineation of "climatic patterns." We need to investigate their economic significance; their relation to entrepreneurial risk and uncertainty; their bearing on economic stability. We need to explore means for attaining and maintaining economic stability in a region of climatic instability. How can firms "roll up and unroll" like a corn leaf to survive in the face of climatic changes?

The economic analysis of the inter-relatedness in production of geographically separated resources. Agricultural land resources in all areas of the nation exhibit a pattern in which the characteristics of the resources at one point are different from those at another point. But only in the West are these resources, though at widely separate points, commonly organized into single agricultural economic entities. In the West acute economic problems arise because the characteristics of the agricultural resources associated in a single firm are often widely variant and frequently are not combinable at all or only with great difficulty in proportions that permit maximum productivity. Typically in much of the West, the "firm" in agriculture is not a localized geographic unit. Often different types of grazing and hay lands must be associated in a single firm and geographically they may be located many miles apart. The pioneering study of sheep migration in the inter-mountain region by Hochmuth, Franklin and Clawson is a good example of an excellent start in research into this problem.²

Irrigation farming exhibits the same characteristic. The tillable area usually is located at long distances from the source of the water that may be the limiting factor in the economy of the firm. We need to investigate the economic consequences of this condition relative both to the firm involved—its risks and uncertainties, costs and returns—and to the community's and society's concern over the wastes and inefficiencies in the use of water that may arise due to this wide geographic separation.

There is a growing tendency in the West to combine irrigated and dry land resources in a single firm even though they may be miles apart. What are the economic causes and consequences of

² H. R. Hochmuth, Earl R. Franklin, and Marion Clawson, *Sheep Migration in the Inter-Mountain Region*. U. S. Dept. of Agr. Circular 624, January 1942.

this development? To what extent should public policy in development of irrigation recognize it in its plans?

The economic analysis of multiple-use of resources. Nowhere else in the United States does the multiple use of resources have the economic impact it has in the West. This condition is probably a corollary of the condition discussed just previously—that resources used by single firms are frequently not geographically localized—and is also probably a result of the extensive federal ownership of resources in the area—a condition to be discussed later. But all agricultural economists in the West recognize the complex and difficult economic research problems posed by the phenomenon of multiple-use. A single area may be used for grazing by domestic livestock and by game for the hunter, for water production for domestic use and irrigation, for water impoundment for irrigation and flood control, and for recreation. The joint, competing and complementary economic relationships are baffling and obscure but terrifically important. In the West we need, as we need nowhere else in the United States, research into the economic evaluation and the economic consequences of this phenomenon. We need research that will serve as a guide to the public agencies in making their difficult but necessary decisions as to which use or combination of uses in a given area creates the greatest economic return.

The problem is difficult. But we should not pass it by for that reason alone. Only by making a start someplace will paths through the tangle open up before us.

To summarize this section of the discussion, most of that economic research usually called land utilization, or land classification, or type of farming research should in the West be addressed to problems flowing from three significant peculiarities of the western environment—its variable semi-arid to arid climate, the widely separated resources frequently composing or required for the composition of single firms and the multiple-use of much of the West's land resources.

*Problems Related to Institutions Erected to Guide Man's
Utilization of the Environment*

Here in the West our utilization of the environment is guided by a structure of institutions basically the same as those in the United States as a whole. But they exhibit many peculiarities related to the underlying peculiarities of the environment already discussed.

Land economic research in the West should concentrate on these peculiar western institutional differences. For example, private property in land is the basic land institution in western agriculture as elsewhere. But public property in land occupies a more prominent place here than elsewhere in the country. Also, "private property" in water is a vastly different thing morphologically, physiologically, and therapeutically than is private property in the land surface. These peculiar differences in western landed institutions should be reflected in western land economics research.

Research in water rights and water law. Elsewhere in the United States we have research in "land ownership." Generally such research is concerned with the human behavior content and economic significance of ownership and tenancy. It distinguishes various kinds of ownership and tenancy and their relations to resource utilization; it describes the economic and social status of the individuals who compose the relationships; it analyzes the economic relations established between the individuals caught up in the tenure restrictions.

Here in the West private property in water is a crucial and critical aspect of our institutional structure. But research into water rights and water law in any degree comparable to that into property in the land surface is noticeably lacking. We need to devote a great deal more of our attention to describing the content of water law in terms relevant to human behavior, to research into the human behavior and human relationships that flow from water law, and to the economic analysis of water rights. We know as little about the behavioristic content and economic significance of water rights today as we did about property rights in the land surface a generation ago. If land economics research is to get hold of something vital in the West, it must tackle the "property in water" problem.

A listing of suggestive focal points for research into water rights may be helpful.

1. A description of the significance of water rights in terms that bring out their "control, liberation and expansion" of human behavior in the use of water and land surface. To whom do the restrictions and liberations apply and with what economic consequences; what are the magnitudes and costs of the risks and uncertainties of the entrepreneurs and other beneficiaries of water rights?
2. What are the inter-individual, inter-area, inter-state relations and conflicts implicit in water law? What are the inter-use conflicts of water that grow out of the content of water rights?

3. What are the "costs" of water—the "value" of water—in various situations and under various rights? What are the relations between "costs" of water and the "value" of other resources used in conjunction with water, notably the land surface?
4. What are the relations of water rights to resource utilization, to entrepreneurial costs and returns, to social benefits and costs, to efficiency in the use of resources?

In these, and in other focal points that could be mentioned, only the surface has been scratched by economic analysis—frequently the surface is unmarred. Land economic research in the West has a wide open field and a great opportunity in advancing understanding of these problems.

Economic analysis of the public ownership of resources. Nowhere in the United States is the public ownership of resources as widespread as in the West. The land area of the 11 western states is 54 percent in federal ownership; on this area is a significant portion of the supply of merchantable timber and of the grazing resources, and well nigh all the recreation and sources of water for domestic, irrigation, power and navigation uses. These cold statistics do not tell the whole story. Of more vital importance from the standpoint of research in land economics is the further fact that much of the resources on these federal lands is utilized by private entrepreneurs for their private profit. Here is another of those situations peculiar to the West—publicly-owned resources utilized by private enterprise. Where, elsewhere, land tenure research has been concerned with "landlord-tenant" relations—meaning always *private* landlord-tenant relations—here in the West this problem is predominantly one of *public* landlord-private tenant relations. At first glance by the uninitiated, this would seem to be a distinction of academic importance only. But upon analysis a host of intriguing differences come out that lead one almost to the conclusion that it is a wholly different problem.

Just what is and, of equal importance, what ought to be the landlord-user relation between the public agent and the private entrepreneur? What are the freedoms and the restrictions placed by the relation on the behavior of the public agent on the one hand and on the private user on the other? How is the relationship established and maintained? What are the "risks and uncertainties" experienced by the private entrepreneur and by the public administrator? What are the economic consequences to the private entre-

preneur on the one hand and to the public on the other? How can the relationship be established and maintained to the maximum benefit of all parties concerned?

Strictly from the standpoint of the economics of the firm, the problem presents intriguing facets for study. What is the economic impact on the dynamic planning of the firm of the risks and uncertainties peculiar to this different kind of landlord-tenant relation? What economic consequences on entrepreneurial decision, on the combination of resources in production and on the value of privately owned resources flow from the fact that "rents for grazing" on federal lands are administered prices rather than competitive market prices? On the other hand, how can the interests and values of other users of the services of the same land and the interest of society in the maintenance of productivity of the resource be adequately protected?

Research in this field has barely commenced. Little if anything was done on it before two years ago. Now the Western Agricultural Economics Research Council is sponsoring a regional research study of the problems of "public land management" in the West. To date California, Nevada, Utah, Colorado, Wyoming, and Montana and the Bureau of Agricultural Economics have expressed a keen interest in undertaking research in this field. Work has actually commenced in California and Utah.

Another aspect of the problems growing out of the public ownership of land in the West is the impact of public ownership on the fiscal condition of local governmental units. Where and under what conditions does federal land ownership place a fiscal burden on local government? Where and under what conditions does it aid local fiscal conditions? What arrangements might enhance the favorable and reduce the unfavorable effects of public land ownership on the fiscal condition of local units of government?

Economic problems of settlement on new irrigated land. Vast new areas of irrigation are either now opening up for settlement or are planned for the near future under extensive "river basin" development programs in the west. Perplexing questions related to the financing of such settlement are unanswered. Traditionally on federal projects, the government has placed a tract of raw land in the settlers' hands and installed the facilities to deliver water to the high point on the tract. From there on, clearing, levelling and subjugating the land, erecting buildings and fences, putting down

wells, constructing "on the tract" irrigation works, equipping the place with machinery and livestock and providing a livelihood for the family over the few or many years that all of this may take is the entire responsibility of the settler. Either the settler must come to the project pretty well heeled financially or it means a serious burden of debt. Or the finally "successful" settler may have benefited from the investments of time and money made by previously "unsuccessful" settlers. As in all such situations where heavy investments are needed, the pressure of interest charges and the risks and uncertainties of debt operating either through the unwillingness of creditors or the reluctance of debtors or both, results in an uneconomic limitation on investment. Such limitations on investment often accrue to the detriment of the settler and the public through uneconomic production and slow repayment of irrigation costs. The question posed is what sources, kinds and amounts of credit are best adapted to the job. Government development before the settler is put on the tract? Direct government loans for development? Private loans guaranteed by the government? Or should we go ahead in the future as in the past? Comparisons should be made between irrigated areas where various means of financing have been used. Comparisons are particularly possible between no development and full development because full development was practiced on the Wheeler-Case projects constructed before and during the war whereas no development has been traditional on Bureau of Reclamation projects.

These are the new directions for land economics research in the West. The starting point for these new directions is any socio-economic problem arising directly from the peculiarities of the physical environment or from the institutions erected for guiding use and enjoyment of that environment.

SOME NEW DIRECTIONS OF LAND ECONOMIC RESEARCH IN THE NORTHEAST

HOWARD E. CONKLIN
Cornell University

THE directions of research discussed in this paper concern problems associated with:

1. The "urbanization" of the open country.
2. The retreat of the extensive margin of arable farming.
3. The geographic localization of farm income differentials within areas suited to farming.

The first of these phenomena is relatively new in many areas. The other two are older, but research methods and ideas for meeting problems are changing.

The "Urbanization" of the Open Country

I refer here to problems arising from the development of a non-farm segment within open-country populations. Issues raised by concentrated urban expansion along rural-urban fringes are not included. The urbanization of the open country is less spectacular, but has far reaching implications. In New York and a number of other states a majority of the working people in many rural communities are not employed on full-time commercial farms operated under their own direction. A large number of these nonfarm people are employed in manufacturing, trade, and service industries at the present time. When these employment opportunities contract, many of them will be in the same position as similar workers in the cities. Some hope that a small acreage—often of poor land—can provide them protection against a depression. Most will be disappointed, as they have been before. Full-time commercial farming no longer is a business one drifts into and out of in response to variations in an off-farm job.

Most nonfarm open-country residents live in an economic world distinctly different from that of their farmer neighbors. They are, nevertheless, a real part of the rural community. They own part of its tax base, drive over its roads, send their children to its schools, and share generally in the community life. Many of them were raised on farms, so they are at home in farm surroundings even though they are no longer in the farmer's economic world.

How can people in different economic worlds live together in social harmony and economic justice under these circumstances? How should they share tax burdens? How can agricultural service agencies serve part-time as well as full-time farmers? What urban service agencies might extend their activities to rural people in the urban economic sphere? How can the nonfarmers, especially the "agriculturally disinherited" among them, be made aware of the difference between farming to reduce living costs and farming that can compete on a commercial basis? How can everyone be made to realize that the gulf between the economic worlds of nonfarmers and farmers is wide, even though both call the same community home?

These questions indicate an area of research opportunity. Not all of it lies in the field of Land Economics, but a share of it is here. The area is not an entirely unexplored one. There have been studies of rural community adjustments to urban influences, of the relative merits of urban and rural homes for city workers, and of part-time farm operations. The subject needs to be re-examined, however, from broader points of view. Studies now are under way to identify and count the members of important segments in the open-country population. This is the first step and one that cannot be by-passed via Census data. Recent publications report such counts in New York and Illinois. In parts of four scattered counties in New York only one-quarter to one-third of the open-country residents operate full-time commercial farms by even a liberal definition. The Illinois publication reports that in one southern county of that state only one-third of the household heads in the open-country are employed solely in farming. These studies are a beginning in a potentially important area of investigation.

The Retreat of the Extensive Margin

Experience indicates that land abandonment is a continuing process in the Northeast. Observation indicates that we have not solved the problems raised by this process where it stood ten years ago. These problems are quiescent now because of economic forces outside our direct control. They certainly will be outlined in bolder relief in the near future, and we will be worrying again about the fate of some of the identical parcels of land so much discussed last time.

The abandonment of land once used for full-time commercial

farming in states like New York appears to be much less the consequence of soil erosion, mistakes in land settlement and farmer ignorance of optimum factor combinations than the consequence of technical and scientific progress. This progress has increased yields most where yields already were highest and cut costs most where costs already were lowest. It is an accident, perhaps, but in this part of the country, progress has not greatly disturbed the relative economic-opportunity positions of various grades of land. It has stretched, however, the range of the economic-opportunity scale. We can reasonably expect a continued stretching of this scale in the Northeast, and expect land as well as agricultural workers to be technologically displaced in the future.

Some claim submarginal land does not exist. This is quite possible in pure logic where the land market is made perfect, where there are no skewed distributions in command over capital, where buyers and sellers of land are omniscient, and where taxing processes operate ideally. In the real world, little land that has passed by default from fulltime commercial farming can be used by private individuals in any way now known to obtain going rates of return on normal investment and labor. I am forced in honesty, however, to say that most of the abandoned land is in private hands today and that most of the taxes on it are paid in full. Whatever in the way of an economic skeleton still exists (outside of the houses) is supported in a large measure by capital replenishment from outside. It is when this replenishment stops, as it must in a depression, that submarginal land problems reappear.

What is to be done? The biggest job is teaching people the nature of the land abandonment process. It is easier to explain nuclear fission to many persons than it is to explain land abandonment—they have fewer preconceived notions about nuclear fission. Men believe in the land they live by, even though they do not live by it very well. They also find it difficult to concede that new machines, plants and animals, by which poor land can be made to produce more with less human effort, can make that land worth less on the economic scale. These things can be taught, however. We also can teach the techniques by which differences in land can be identified and their significance spelled out. The teaching of these things can help to dry up the capital replenishment that supports misguided attempts at farming, and supports artificially high land values and taxes, in what are now submarginal land areas. This, perhaps, can

open the way for the economic development of these areas by private forest, grazing, and other extensive land using enterprises. Then a claim for the non-existence of submarginal land can hold a greater share of truth than it does now.

Research can explore the economic possibilities of alternative abandoned land uses, examine alternative institutional arrangements affecting private enterprise on this land, and consider public enterprises that might be established in these areas. It has been recommended more-or-less as a matter of course that abandoned land be returned to forests, without a careful investigation of the economic returns promised by forestry. Forestry has been promoted as a religion rather than on the basis of hard economic facts. As a religion it has made meager progress in comparison to its potentialities. Economic facts may reveal the bottlenecks. Grazing, recreational and other extensive uses also can be investigated.

The Localization of Farm Income Differentials

Research to discover reasons for variability in incomes from farm to farm was begun in this country some years ago. It probably was recognized ahead of time that the functional relationships underlying this variability are very complicated. Progress has been made however, and various patterns of stochastic causal and associative relationship have been discovered. One of these patterns is geographic. Farmers in certain areas have been found generally to be making higher incomes over the years than farmers in certain other areas. It also has been found repeatedly that these income patterns often are associated with geographic patterns in such physical factors as soil, climate, topography, and location.

The land classification system now identified with Cornell University grew directly out of these findings in farm management research. This system has as its fundamental supposition the generalization that there are geographically localized differences in farm incomes within such areas as states and counties, that these are mappable at a reasonable level of categorical and cartographic detail, and that they persist long enough to give these maps a sufficiently long useful life to justify the cost of making them. It has as a closely related supposition the idea that localized income differences are associated with physical land differences. Numerous operating assumptions also have been necessary. These also have been based upon farm management research findings. The use of

the roadside farm appraisal (the widely known, so-called building classification) has involved one of these operating assumptions. In this case it is assumed that the evident appearance of a farm and its buildings is related to the income of the farmer. The fundamental suppositions establish the general character of the classification system. The operating assumptions are used in carrying out the classification processes involved in the system. Operating assumptions may be changed or replaced within limits without changing the essential character of the system. Actually, however, the distinction between fundamental suppositions and operating assumptions was not clearly recognized early in the classification work.

A variety of farm characteristics always can be found in any area that are related, causally or otherwise, to farm income. In New York State intensity of land use, as inputs per acre, is one factor generally related to farm income. There are others similarly related, but as it happened, intensity was chosen early in the classification work and explicitly advanced as the classification criterion. Among the other farm and land characteristics that are related to past and probable future incomes in various degrees, a group was chosen that offered the advantage of being easily ascertainable, usually on rather rapid visual inspection. These were termed the "bases" of classification. They included principally the outward appearance of farms and farm business, kinds of crops and other vegetation on the land, soil characteristics, and assessed valuations. These particular farm and land characteristics were found to be suitable indicators of farming success in the areas of the state where classification work was begun and were made a part of the classification routine on that basis.

Fundamental suppositions, criterion concepts, and operating assumptions were confused with one another in the standardized classification routine that crystalized out of the early classification efforts. This routine was adequate in the areas where it was born, but is not suited to all major areas of New York. It is unsuited, moreover, to many areas outside New York, and workers elsewhere often have been unable to separate from it the ideas that might have been useful to them.

Regardless of the deficiencies we think we see today in the original form of the system, it, nevertheless, was outstandingly successful in the circumstances where it first was applied. It was simple, and at the same time portrayed differences farmers them-

selves could see when they stopped to look. I think this relatively simple device has contributed more to a general understanding of land use problems in New York State than any other single activity. The system also represented a fundamental departure from established land classification systems at the time it first was advanced and for this reason it stimulated basic thinking about land classification. Up to that time no major classification system had discriminated among levels of economic opportunity within major use areas. This feature of the system still seems to have no meaning to some land economists. I shall attempt later to show how an acceptance of traditional theories of land use and farming returns can cause a blind spot in one's comprehension at this point.

The recent re-examination of the system by workers at Cornell was prompted by the apparent unsuitability of the original routine in certain areas within the state and also by a desire to spell out the fundamentals of the system in a manner more widely applicable and understandable. In this they have drawn heavily on the work of men who have applied the fundamental ideas of the system to a variety of conditions both in the United States and Canada. Workers in Virginia, Canada and the State of Washington have contributed especially. Attempts also are being made to tie the system into traditional theories of land use and farming returns. This can provide logical shoring for inductively derived notions and a linguistic common denominator for those who approach land problems from established theory and those who approach them via the everyday problems of farm management.

As visualized now, the land classification methods being used at Cornell have more in common with farm appraisal techniques than with any other clearly identified process in this general field. The methods and the thinking go well beyond a mere estimate of probable sale price, however. They go into that area where lie part of the factors determining such things as debt repayment ability. In this respect, then, an application of the system parallels the work of a qualified loan representative, who not only estimates sale price, but also recognizes farm income differentials that lie beyond this. The land classifier, of course, tries to visualize a farm in terms of a farmer typical of the area, rather than to evaluate the ability and integrity of the individual farmer. His appraisals also are much more hasty and his results are recorded in a categorically and

cartographically generalized form. The intent is much the same, however. In fact, the land classification system now is referred to as an income-expectancy type of classification.

In this form, the large judgment element present in the system is obvious. It can be judgment objectively exercised, however, and surely is judgment in an area of immediate practical concern to farmers, farm lenders, agricultural service personnel, governmental agencies, and many others. With judgment elements clearly recognized and with fundamentals separated from expeditious adaptations, it is possible to critically analyze the system and to outline directions of thinking and research that offer promise of improving it. It is possible also to visualize the likely usefulness of the system in new circumstances.

First, however, we should clear up some inconsistencies between the fundamental suppositions of the system and established economic theory. As always, we must accept the theorist's disclaimer to exactness and complete generality. We must hold him, however, to portraying central tendencies in stochastic relationships through time and space, if he means to have his theories approximate real world situations. With this central tendency idea in mind, we can say that traditional theory categorically denies the possible truth of both the principle and associated suppositions of the income-expectancy system of land classification. In traditional theory, land either is made a residual claimant, or is attributed a marginally imputed share. In either case, non-land input factors are assumed to be mobile in varying degrees and to seek maximum returns across land grade lines. It is presumed, then, that these factors in time attain a substantial degree of equality in returns for equal input effectiveness everywhere they are employed. Types and intensities of land use are adjusted to equalize marginal productivities for all inputs in all directions of application. The land market capitalizes the share left for, or imputed to, land in establishing the market price of this input factor. All dollars invested in land at going market prices thus earn equal rates of return everywhere. In this body of reasoning, then, a farmer should receive neither more nor less for either his time or his capital than any other farmer, unless his time or his dollars are more or less effective input factors.

This theory leaves no place for persistent geographic localizations in farm income differences, except under some rather far-fetched

assumptions. The most often promoted assumption of this kind maintains that geographic differences in farm incomes within most limited areas are the consequences of geographically localized differences in the managerial abilities of farmers. There are both empirical and logical items of evidence to refute this notion. The idea appears especially out of place when one leaves the marginal zones and makes comparisons between high and very high farm income areas. Similarities in cultural and educational backgrounds, intermarriages for that matter, seem to rule out the likelihood of inherent differences in farmer abilities. If the differences are acquired, then there must be an external cause. Even not acquired there may be a sorting of managerial ability by grade of land. But why should differences in managerial abilities become localized without an external cause? If, indeed, economic opportunities are the same on all land, why should the more capable farmers gravitate to areas where soils are deeper, and the land naturally better drained, better watered, less steep or otherwise physically better suited to agricultural operation?

Actually it seems quite meaningful in the real world to consider the price a farmer pays, or promises to pay, for his farm as going a long way toward determining his degree of subsequent financial success, and then to focus attention upon the characteristics of the land market and of the participants therein. The land market comes far from embodying a theoretically perfect process, its participants are far from omniscient, and they come to it on widely unequal footings. Most farmers do not possess sufficient knowledge of land over wide areas to justify a contention that the prices they establish in buying and selling farms represent an accurately capitalized value of any explicitly recognized return. They do recognize some differences in land to be sure, but there are good grounds for expecting them to underestimate the actual differences and therefore to average their prices across land grade lines to a considerable extent.

There also is a highly skewed distribution in command over capital among farm purchasers. Many people have the price of a cheap farm, but few have what it takes to buy a high priced one. Almost certainly this skewed distribution in command over capital causes more intensive bidding at the lower end of the price scale.

Lack of complete knowledge and a skewed distribution in command over capital combine with desires to be "one's own boss" and desires for security, to produce an actual land market that is far

from the theorist's ideal. The discrepancies between the actual and the ideal follow a generally systematic pattern, however. They are such that degree of financial success in farming very commonly is an increasing function of land price. There are definite limits, however, to the generality of this relationship. Where differences in land are sharp and clearly recognized and where capital is equally available to the groups on each side of such land lines, this relationship ceases to hold. For this reason we often find equal economic opportunities between highly priced land areas in irrigation districts and cheaply priced lands in grazing areas above the high-line ditch. For this same reason, too, we find roughly equal average opportunities in farming between Wyoming and New York. Land in Wyoming is not confused in any buyer's mind with land in New York, even though land within either state may be confused with land farther down the road.

It is in this general fashion that the income-expectancy system of land classification is being tied into established theory and given logical support.

With this background let us turn to thinking and research that might improve the present income-expectancy system of classification. The following are possible directions such thinking and research might take:

1. Toward a more precise expression of what is meant by income expectancy.
2. Toward a re-examination of the suitability of various easily observed or measured indicators of income, toward a quest for new indicators, and toward refining techniques for stepping from indicator information to income estimates at the individual farm level.
3. Toward more precise technical definitions of land classes as cartographic groupings of farms.
4. Toward more systematic procedures for drawing the land class lines that create the cartographic groupings of farms, and toward devising and applying more refined statistical techniques in measuring the "goodness" of a given set of lines and in maintaining uniformity within land classes among widely separated areas.

The making of income-expectancy land class maps will remain a judgment process, in large measure, regardless of the thinking and research that is done. The classifier must add up a large

amount of information that can never be summed reliably in any mechanical manner. He also must look into the future if his work is to be most meaningful. Judgment processes can be ordered and aided, however, and the kinds of activities suggested above would help in this way.

Farming returns, and therefore farm income expectancy, can be measured in many ways. In land classification work the particular measure adopted may vary with the objectives and circumstances. In an area where farms are predominantly family-sized and owner-operated, the farm management measure known as "labor earnings" is likely to be appropriate. For land classification purposes, however, such a measure should be modified to span a period of years, perhaps the ordinary working life-time of a farmer. Generally, the measure chosen should be one whose values will be closely correlated with such things as debt paying ability and general level of living. For special purposes and in certain circumstances labor earnings per man would be a suitable concept. Other concepts may be appropriate in other instances. A "typical" or "modal farmer" concept also must be part of any expression of what is meant by income-expectancy. We do not classify land for specified individuals but for the "most likely" individual.

In any case, however, the land classifier will not often be able to measure even actual past incomes in the areas he classifies. He seldom has the money. Instead he must use easily observed or measured indicators. The appearance of a farm is such an indicator. Soils can be indicators; so can kinds of crops, size of farm business, rates of production, market value of capital, and other farm and land characteristics. These factors possess indicative value to the extent of their correlation with long-run incomes. They need not be causally related to income to be useful in the classification process. Their relationship to income need only be stable in a known space and time. It is obvious that some indicators are likely to be more satisfactory than others. The usefulness of an indicator depends on its cost, on the one hand, and its closeness of relationship with long-run incomes, on the other. An adequate interpretation of indicator information of any kind must rest upon a knowledge of regression functions. These regression functions need not be continuous and precise, but they must make it possible to put individual farms into significantly different income-expectancy categories.

At present there are no technical definitions of income-expectancy land classes. It will be very difficult to construct such definitions. Land classes are cartographic units and each unit nearly always must contain the full range of universe values if it is to be of reasonable size and not unreasonably awkward in shape. Land classes can be distinguished most meaningfully in terms of various characteristics of frequency distributions. They should not be distinguished exclusively in terms of one characteristic of these distributions—the arithmetic mean, for example. I believe that the task of defining land classes in technical terms offers a real opportunity for imaginative thinking.

The development of systematic procedures for drawing land class lines is an even more difficult task than the construction of land class definitions, though closely related thereto. It is strictly an art at present, even when individual farms have been assigned to suitable categorical income-expectancy classes and the corresponding designations noted on maps. In drawing these lines attention must be given to the spatial distribution of farms with different characteristics, as well as to the kinds of frequency distributions shown on the tabulator when the job is finished. Statistical measures can be used as partial tests of the goodness of a classification and may replace to some extent a need for systematic procedures in the drawing of lines. No statistical measures yet known, however, can reflect satisfactorily the spatial element.

It is possible to visualize a more "scientific" income-expectancy classification of land (perhaps we should say, of farms), but there are plenty of unsolved problems along the way.

I should not close this paper without pointing out explicitly that the income-expectancy system of land classification is not the long sought ideal that does all things for all men in all circumstances. There are instances where geographically localized differentials in farm incomes do not exist in a mappable pattern, cases where dispersed non-contiguous operations make mapping on a farm unit basis impossible, cases where major use issues are paramount and must be settled before any persistent pattern of incomes will crystallize, cases where institutional arrangements constitute the most significant limiting factors, and cases where the problems at hand involve helping a population on the land keep body and soul together in an unfavorable situation from which it cannot escape. In a number of widely separated areas, however, the system has

proven valuable. Maps made with it have helped many private individuals and organizations directly and have helped others indirectly by serving as guides in the formulation and promotion of governmental programs and policies. Such maps can help solve a general problem in so far as lack of information underlies differentials in economic opportunity upon the land.

Is the making of these maps research? I will side-step this by saying that a land classification program of this type often can form an important part of a departmental research program. It can identify significantly different strata for sampling purposes and it can aid materially in constructing the kinds of observational designs that are beginning to be suggested in farm management and related fields. It also can form a nucleus around which it is possible to organize ideas of what constitute optimum combinations of factors of production on various lands.

DISCUSSION

MELVIN L. UPCHURCH

Bureau of Agricultural Economics

Professor Conklin says that land economists in the northeast will be concerned with problems related to the urbanization of rural areas, retreat of the extensive margins of agriculture, and with land classification. Let us not condemn too readily the urban employee for wanting to live in the country. Although social security has improved his economic position, his real problem is that of maintaining urban employment rather than proper adjustment to his rural environment. He may need some help in understanding the limitations and possibilities of his part-time farming venture.

From Professor Conklin we have again heard about the "Cornell land classification system." (The fact that it is a farm classification system he parenthetically admits.) Drawing lines on a map around areas of good farms and around areas of poor farms may be a desirable starting point for research in land economics. Such a procedure graphically illustrates the occurrence of certain observed characteristics in much the same way that a bar chart graphically portrays the occurrence of items in a statistical array. The delineation of areas having certain characteristics is valuable for extension work and for other purposes. We do not need, however, to rationalize the making of a bar chart by referring to economic theory. It does not take a theorist to observe that some farmers have high incomes and some low even when the observation is made by visual inspection of his buildings or other assets rather than by an accounting system. It may take a good theorist, however, and painstaking research to discover why some farmer's incomes are high and others low.

Perhaps a fruitful way to consider what is new in land economics re-

search, at least in the West, is to consider the major trends in land use and landed institutions. In the West we have seen a rapid expansion of irrigated land in recent years and will see further expansion in the near future. Secondly, we have seen in recent years much greater control exercised over our public and private range lands and in the near future I think we will see a much more intelligent and intensive use made of them. These two major trends in the West should be of primary concern to land economists.

In the field of irrigation, land economists have much to do. We must study further the economics of organization and operation of irrigation districts and other institutions peculiar to irrigated farming. This list is not at all exhaustive. There are many other problems that need attention.

We have much to do in the field of the economics of range land use and control. Experiments to determine how we may practically increase the production of feed from range lands are of fairly recent origin. These experiments are showing rather startling possibilities. The economists have much to contribute in helping to determine how we can use range land more intensively. Problems of ranch organization and management are involved.

Land economists in the West must be aware also of the fact that government, all levels of it, is a more direct factor in the economic environment of western agriculture than in other regions. It is not uncommon for a western producer to deal with one or two or more government agencies to obtain grazing for his animals; he deals with another to help him control predators. He irrigates his land with water, the right to which is protected by the state. This water is brought to his place by a municipal corporation which collects for this service through the county taxing mechanism. This municipal corporation may, in turn, receive the water from a federal project or a public corporation. It is evident that the actions of government are a vital and determining force in western agriculture, as vital perhaps as the prices received and costs incurred in production. A new direction in land economics research would be to develop techniques for properly evaluating this factor in our economic analysis.

DISCUSSION

VIRGIL GILMAN

Extension Service, U.S.D.A.

In my discussion of these excellent papers I want to direct my remarks to making land economics research useful. In organizing and carrying out any research project many things can be done to facilitate the utilization of the final results. It is necessary to develop a clear idea not only as to *what*, but also as to *whose*, problems we are tackling; in other words, whose land use interests are involved and who the users of anticipated research results will be. This helps focus the analysis and aids in selection of illustrative materials that will appeal to the users.

Participation by people who live upon and use the land is of great im-

portance. As prime movers whose initiative and cooperation is essential in any program of land use adjustment they have an important layman's contribution to make in identifying the problem and assisting with certain phases of the study. I wish to emphasize this point above all others in these comments of mine. A close, progressive, working understanding between the man of science and the man of the soil is, I feel, of fundamental importance in paving the way for the utilization of research results.

In passing it is important to note that land economists can very properly carry on some research for the purpose of improving their own science; for example research work regarding such things as land classification, land valuation, the application of theories of location, and the character of institutions affecting land use.

Both papers stress the great importance of basic physical data. One of the fine things about the income-expectancy classification discussed by Dr. Conklin is its careful tie-in with soils and other resource data. Dr. Kelso's proposal for studies of the economic consequences of a fluctuating semi-arid climate should yield very useful information. Men everywhere in the West are intensely interested in the weather and its bearing on problems of risk, uncertainty, and economic stability. I feel that we need much more information on soils, especially expressed in terms of potential productivity under alternative soil management plans.

I was much interested in Dr. Kelso's discussion of the inter-relatedness of geographically separated resources. The factor of distance is important but so is the factor of *pattern*; the many area combinations in which resources occur. His suggestion for research into this problem in terms of agricultural operating units is an excellent one. However, since agricultural uses are often intermingled by areas and geographically with non-agricultural uses, an analysis of agricultural operating units might well be accompanied by an economic analysis of non-agricultural uses. I wonder if land economics research doesn't often neglect the economics of forest, grazing, recreational, and watershed use. Dr. Kelso in his discussion of the need for economic analysis of multiple-use resources, and Dr. Conklin in his discussion of important research opportunities in exploring the economic possibilities of alternative abandoned land uses point out this shortcoming quite clearly.

Recognition of legal institutions as factors affecting the use of land resources is most properly emphasized in Dr. Kelso's paper. An economic analysis is much more useful when accompanied by an analysis of the institutional framework within which economic activity is carried on.

Regarding the economic analysis of public ownership of resources I wonder if it wouldn't be more feasible to look upon the whole tenure structure as a *combination of public and private rights* and to analyze both types together. I feel that the goal we seek is a good combination of public and private use rights. The necessity for such a combination grows out of the varied character of our Western land resources, the natural overlapping of private and public interests at many points, and the natural, desirable, and inevitable intermingling of two or more types of use in many areas.

I was much impressed with Dr. Conklin's discussion of an income-

expectancy type of land classification. He indicated that this relatively simple device has contributed more to a general understanding of land-use problems and land economics processes in New York State than any other single activity. This indicates that this procedure is a useful reconnaissance way of looking at farms and at land in a systematic manner. I am familiar with a similar classification made in a number of Washington counties and I am certain that the maps and accompanying descriptions made there have been an eye-opener to many who were not aware of the great variation in soils and farm income from area to area.

Dr. Conklin makes a statement to the effect that the income-expectancy system of land classification is not the long sought ideal that does all things for all men in all circumstances. This leads me to make an observation of my own, namely that any one general land classification procedure, like any one general economic theory, is often inadequate or unsuited to a particular problem situation. I am inclined to look upon land classification as a type of tool the design of which must be varied, sometimes radically, to fit the *time* and the *place* and the *problem*. I feel, too, that any economic classification map is apt to be a broad generalization based on many types of information. Any generalized land classification map needs to be explained in terms of soils maps, type of farming maps, land use data and other types of specific information on which the generalization is based.

Dr. Conklin's discussion of the need for bringing up to date our knowledge of the urbanization of open country areas is certainly timely and his list of questions is an excellent one. This urbanization development is not peculiar to the East; we have Western versions of it in the Pacific Coast States; here in the Rocky Mountains, and even in desert areas in the Southwest and the Great Basin. I have long felt that we are too prone to divide the economic universe into two big subdivisions, "agriculture" and "industry," and to overlook a broad middle zone of economic activity and living that is some mixture of the two.

I agree with Dr. Kelso that the economic problems of settlement on new irrigated land are going to need a lot of attention. His discussion is largely in terms of public policy and program problems of financing development. In addition, as he indicates, there are many farm organization, farm management and family living problems on individual farms. Some progress has been made, some excellent research work has been done, but we still have a long way to go.

In reading the papers given here and in reflecting on the scope of land economics, I am much impressed with the fact that land economics is indeed a social science; perhaps the most social of them all. I say this because of the number of other disciplines with which the land economist is constantly in touch—ecology, farm management, sociology, political science, public administration—to name major ones. I understand that the modern trend throughout the world of scientific scholarship is to try to bring workers in the various fields of science into closer working relationships with each other on a team work basis. If this is true, then there is in land economics a point of view, a method of operation, and a background of experience that is very much in tune with the times.

DEVELOPING AND APPLYING PRODUCTION FUNCTIONS IN FARM MANAGEMENT

IRVING F. FELLOWS
University of Connecticut

PRODUCTION functions are being discussed with increasing frequency in economic and related literature. Actually, economists are adopting new terminology to express old ideas. In the mathematical sense, a function is simply a description of the definite relationship that exists between variables. Research in farm management has long been aimed at the discovery of such relationships. Outstanding examples are the studies in the 1920's by Dr. Spillman of the relationship of crop yields to fertilizer applications. Later, the pioneering work of Tolley, Black, and Ezekiel initiated input-output studies covering many problems. Dr. Jensen and co-workers in the field of dairy husbandry made a major contribution with their research on the relationship of milk production to feed intake. These studies and countless others, whether they used the terms production coefficients, crop and livestock response, or input-output ratios, all sought to establish relationships between variables so that prediction might be made with greater certainty.

Adopting the terminology of production functions has several advantages. As mathematics becomes a tool of the economist in the expression of ideas, it is helpful to adopt the definitions of that discipline. A common language assists in comprehension and solution of problems. Mathematical manipulation of a function is possible and leads to greater precision and facility in the use of cost curves. Total, average, and marginal cost concepts can be expressed and integrated. When the interrelationships of several variables upon a dependent factor is studied, graphics can no longer serve and the function equation must take its place. More and more often, production economists are asked to evaluate response when the influence of several factors are felt simultaneously.

Production functions are useful at several levels in farm management research. In the phase of agricultural policy that affects agricultural production, functions can be used to summarize the relationships between aggregate factors. This knowledge could be helpful in determining the impact of policy and the adjustments that might occur on farms, between farms, and between areas. Some attempts have been made to develop production functions

showing the relationship between organizational characteristics and farm output for groups of farms. Heady, Tintner, Brownlee, and associates at Iowa State College have published several papers dealing with this level of use. The most common level has been one concerned with crop and livestock response to variable conditions. Most of this work is well within the scope of the physical production scientists. Examples of such research are familiar to all and need not be elaborated here.

In farm management research and extension at Connecticut, we have taken the position that it is at this latter level—physical production response—that production functions can be of greatest help. True, such research lies within the technological sphere, but therein may be one of the greatest benefits. Farm management may be considered as an integrating vehicle for physical production data. By the application of price or cost information, input-output relationships can be appraised to determine combinations that will achieve given ends—efficient resource utilization or profit maximization within welfare considerations. Cooperation with the physical scientists helps to indicate to each group the problems and needs of the other.

The decision stems also from another tenet—that the grouping of farms on a type-of-farming, type-of-enterprise, size-of-business or any of the familiar bases used in farm management has generally failed to give help to individual farmers in their management problems. Efficient resource utilization, within the framework of the limitations that exist on each farm, cannot be achieved by resorting to the factors-affecting-farm-profits approach derived from group data. Across-the-board recommendations to increase crop indices, to decrease investment per animal unit, to enlarge the size of business, and the like, are in opposition to primary principles in economic theory and underestimate the individual management problem.

It was on somewhat similar grounds that we chose not to use production functions descriptive of organizational characteristics from groups of farms. If these functions are used to initiate adjustments on individual farms, the same criticism can be made as of the factor-analysis approach which tends to recommend the general application of specific management practices.

Farm management as a science and an art is a much more subtle problem. It is a tremendously personal problem, too. Each situation

is filled with human and environmental conditions that border on uniqueness. Yet if we assume rational action, we have available the economic theory and the mechanics to help meet this problem. Using physical production functions as our building blocks and applying price or cost data, it is possible to synthesize economic models. After they have been altered to meet real limitations that may exist on a particular farm, the models can serve as goals or objectives that indicate possible directions of adjustment. Also indicated are the changes that are necessary in resource organization and use, an approximation of the costs in terms of expenditures, an estimate of returns, and the impact upon personal value systems and existing habits. We believe such a program brings help to the individual farmer in his role as an entrepreneur. Alternative opportunities are set up and with each is associated the management practices that are required and the returns and costs in monetary and human values. With this knowledge each operator is then able to choose which alternative maximizes returns within his value system.

Having defined production functions and discussed their usefulness in general, and in particular for farm management research and extension in Connecticut, perhaps it is time to make a major confession. In my opinion, adequate physical production functions are not available now nor will they be in the reasonably-near future unless there occurs a marked change in agricultural research. Research on farm problems has been done at scattered points throughout the country. Scientists working within this framework have naturally worked on those problems of greatest interest to themselves and to farmers in the area in which they are located. As a result, spotty coverage has been given farming problems. Moreover, because of our propensity to classify and order, institutional segmentation has been established. Problems have been viewed in segments much as the blind men "viewed" the elephant. Agricultural engineers have been primarily concerned with structural strength of a barn, a silo, or a piece of haying equipment. Dairy husbandrymen have considered hay or silage from a feeds or feeding standpoint. Agronomists have attempted to develop more useful forages. These approaches are necessary and desirable but what is lacking is an integrated research plan. Lost somewhere along the way is the problem that transcends all others—the use of farm resources to achieve maximum profit.

Because of deficiencies in sampling, experimental design and control, and analysis, only fragments of input-output curves have been developed, and these fail to show the interrelationship of important variables. Practically none of the studies have pushed experimentation to the point where total output levels off at a maximum with continued application of inputs. Progress is being made in research on technological relationships, however, and in time economists may be able to assist on the problems of resource allocation and utilization on a farm through the medium of function equations. Until that time, assistance can come from a less refined and more time-consuming method—synthesizing efficient farm units by budgeting the influence of alternative set-ups with physical relationships based upon standards of performance.

A short discussion of a project we have recently completed at Connecticut in cooperation with the University of New Hampshire and the Division of Farm Management and Costs of the BAE may help to visualize this method. The study is entitled, "Cost Reduction in Dairying," and the purposes were to establish ideals in resource organization and utilization within present technological limitations and given price relationships, to determine areas wherein cost reduction opportunities lay, to summarize existing standards of performance on crops and livestock and point up the gaps that exist in these data, and to indicate the usefulness of this approach in farm management. The theory associated with the determination of economies of scale was used as a vehicle to achieve these objectives. This was done because the scale technique is almost a discipline within the discipline of economics. Agricultural economists could immediately construct the conditions impinging upon the study. Furthermore, the technique neatly accomplishes the several objectives. As the scale curve is drawn tangent to firm curves representing the most efficient utilization of resources at different size, it is necessary to collect and integrate physical response data. Gaps in the existing information are indicated in this process. The technique also sorts opportunities for cost reduction into those associated with changes in the size of business and those associated with the organization and use of resources in the business.

Synthesizing the farm business is dependent upon input-output data for segments of the production process. I call these data standards of performance because they are over-simplified versions

of production functions. They represent superior but attainable levels of accomplishment under precisely defined situations when many of the usual variables are eliminated. In later application to individual farm planning, it is possible to show how the performance rates are altered by introducing some realistic variations into the situation. But in synthesis, we used the unadjusted standards such as alfalfa yields of 6000 pounds of hay per acre from a medium productive soil subjected to specified treatments, total milking time of five minutes per cow per day for a given man-equipment-barn combination. Once these standards have been obtained for a sufficient number of segments, synthesis of the average cost curves and scale curve is possible. Achieving the most efficient combination of resources and practices from the numerous alternatives is accomplished by budgeting to recognize marginal concepts and interrelationships of adjustments. Gradually the farm unit takes form around one definite item, such as size of the labor force, to give firm curves for the farms of different scale.

For the most part, performance standards were obtained from the studies of agronomists, dairy nutritionists, etc. Some standards, particularly those dealing with labor and equipment use, were developed by agricultural economists at New Hampshire and Connecticut. In developing these rates, physical input-output relationships were studied either on vanguard farms or on experimental farms. An approach to controlled conditions was achieved even under a farm environment by breaking jobs down to elements which could be precisely defined and which were subject to repetition. A description of physical inputs and outputs and the conditions under which they operate was secured. Comparisons between and upon farms were then made to determine the highest production efficiency for each necessary element in the job under any standardized condition one might select. A performance rate, arbitrarily set somewhat below this highest level, was then derived for the production phase with an indication of variability around this rate due to physical differences in such things as hauling distances, stoniness, barn layout, operating speed, load sizes, etc., that will vary between farms from the standardized situation.

More valid comparisons can be made between labor-equipment combinations through the use of these standards than by using the usual average data. By combining element requirements derived from the most efficient operators, an approach to experi-

mentally-controlled conditions can be achieved. For example, usual average data for haying equipment reflect differences in field conditions, labor capabilities, equipment conditions and management characteristics, as much as they do the basic differences between equipment. The construction of standard rates minimizes such unwanted influences by eliminating some of the physical differences, and by using a selected sample. A basic assumption is that there is less variation in management characteristics between the most efficient operators of groups using different kinds of haying equipment than there is between all operators in the groups.

In the Farm and Home Planning activity of Connecticut extension work, these standards have proved very helpful. In the step-by-step adjustments on his farm, the operator has been able to visualize what levels of accomplishment were reasonable under his situation. Average rates, on the other hand, have a nebulous character which does not permit meaningful application to an individual problem.

The usefulness of standard performance rates as a device to improve farming practices is demonstrated by the spread of the rapid milking method. After studying this problem, standards were established that were related to the performance of those dairymen who were using superior techniques. The goals and associated practice recommendations were then made available to other farmers. By applying these methods, milking time has been reduced on many farms even though, in this case, there was the problem of training the dairy cow as well as the dairymen. Another example shows how standard performance rates and associated techniques were used to improve hay-harvesting methods on an individual farm. After studying the problem and comparing his own operations with those which are recommended, the operator in this case was immediately able to reduce by 30 percent the time required to move one load of hay from the field into the mow. By making alterations in the barn and adding other installations, the time per load could have been reduced to 45 percent of the original requirements.

In summary, this presentation has emphasized that production functions are basic tools in farm management research. Although they can be applied at several levels, we believe that they are most helpful when used to express the interrelationship of input variables upon output in crop and livestock production. These data are necessary information when economic models are constructed to

assist the individual farmer by indicating possible directions of adjustment and the steps in achieving these objectives. Inadequacies in existing physical input-output relationships warrant the use of a less complex type of function which we have called standards of performance. These standards have been very valuable in farm planning to initiate individual adjustments.

Throughout this paper, emphasis has been upon the role which farm management plays in achieving adjustments on individual farms. We believe this is a necessary starting point before we can attack the broader problems of intra- and interregional competition, and of resource ownership and control. We believe that these problems along with the individual's management problems are met best by concepts of what could be rather than what is. Therefore this is the area and the methods we have chosen for our work in farm management research.

MEASURING THE MANAGEMENT FACTOR

F. J. REISS
University of Illinois

IN THE analysis of farm financial data it is a common practice to evaluate the level of management on the individual farm as a residual earning expressed as management earnings, operator's labor earnings, rate earned on the investment, etc. These factors are in a sense measures of management; but they are not entirely satisfactory for this purpose for perhaps three main reasons: (1) they are "after the fact" measures: they can be used only after the activity has been completed, and hence they have no prior predictive value; (2) they are not reliable as measures of management because they also reflect windfall profits and losses entirely apart from management. Likewise, they are not corrected, in the usual methods of calculation for earnings which result from varying degrees of exploitation of both human and physical resources; (3) and, finally, they measure a residual output rather than management as an input factor. It is quite conceivable that varying proportions of land, labor and capital associated with the same level of management will yield varying residual returns as measured by the factors mentioned.

So we are interested in finding a measure for the management factor per se, and such a measure as will admit, if possible, of predicting the level of management prior to the completion of the activity in question. Our problem then is a special segment of the more general problem of predicting human behavior.

Prediction research in human behavior concerns itself with two general problems: (1) finding a suitable criterion or measure of success in the activity, and (2) finding those situational and personal factors which are related to success, or are indices of factors which are related to success in the activity. Given the criterion and the predictive factors, appropriate statistical techniques can be applied to measure the degree of relationship and provide a quantitative basis for making predictions.

Predictions are usually based upon the degree of relationship between the criterion and one or more of three main types of predictive factors: (1) previous performance, (2) proficiency tests, and (3) personal characteristics. The first one requires that the individual be engaged in or have had previous experience in the activity.

Therefore it has limited value for vocational guidance to rural youths who have assumed no farm managerial responsibility. Proficiency tests measure previously acquired skills or knowledge, and therefore have limitations in the management field in addition to the difficulty of administering such tests. Personal characteristics admit a much broader interpretation of fitness for a given activity, but they present a more difficult problem of appraisal and quantification for prediction purposes. Nevertheless it is along this line that we are attempting to measure individual differences in farm managerial ability.

With these general methods and techniques in mind we are ready to approach the problem of measuring the management factor in farming, or predicting the level of success most likely to result from the personal and situational factors surrounding the individual farm operator.

One of the first problems is finding a suitable criterion of success in farming. In addition to the comments I have already made on the conventional measures of farm success, I must raise the question as to whether we can accept maximization of money income as the sole end and goal of farming. What about the non-material satisfactions in farm life, in effort directed toward the enrichment of community living, and in the use of leisure time in the pursuit of the cultural arts?

Wallace's Farmer, an Iowa farm magazine, conducted an opinion poll among Iowa farm people in the fall of 1947 on the question, "Who is a farm success?" The persons interviewed were asked this question: "Which of the following statements best describe your idea of the most successful farmer? Pick three statements marking them 1, 2, 3 in order of choice." The seven statements from which they were to choose were:

- "1. The one who gets the biggest yields per acre.
- "2. The one who follows the best soil conservation practices.
- "3. The one who is able to retire at the earliest age.
- "4. The one who gets the most income per dollar invested.
- "5. The one who has interests and satisfactions that do not depend on income.
- "6. The one who gives his children the best education.
- "7. The one who is the best leader in the community."

On the basis of first choices only, 43 percent of the men interviewed gave first choice to the best soil conservation, 16 percent to the most income per dollar invested, and 12 percent each to the big-

MEASURING THE MANAGEMENT FACTOR

gest yields per acre and the non-material income and satisfactions. The women agreed with the men on soil conservation with 38 percent of their first choices, but gave second place to the non-material satisfactions with 19 percent of their first choices. The biggest yields were third with 15 percent and the highest return per dollar invested fourth with 13 percent.

These were the results as published in *Wallace's Farmer*, November 1, 1947. However, using a weighted average (weights of 3, 2 and 1 for first, second and third choices respectively) for the men interviewees reduces soil conservation to 30 percent (still first place), raises most income per dollar to 18 percent (still second place), raises non-material satisfactions to undisputed third place, educating children to fourth place, and drops biggest yields to fifth place.

I quote this survey because the results are interesting, and because it illustrates some faults in a technique that has been used in studies on the management factor at Illinois and in other states. Aside from the statistical techniques employed in making the summary of such a survey, it must be recognized that the interpretation of the results must definitely be limited to the choices made available. For example, Iowa farmers may have felt that the one who has the best kept buildings and the neatest farmstead is the most successful, or the one who owns the most land, or farms the largest number of acres, or grows the tallest corn; but they had no opportunity to say so in this survey.

Furthermore, the degree of intercorrelation between items in the schedule gives rise to interpretations in the minds of the persons interviewed that cannot be treated statistically in the type of answers given. For example, some of these Iowa farmers actually made the statement that soil conservation was necessary to achieve and insure the goal of highest income, and hence they gave it first choice over income because they felt that the income would be a natural consequence.

Enough for the present on selecting a criterion of success. In our future work at Illinois it is my hope that we can introduce sufficient refinements into the measures calculated from our farm records that we may have a suitable criterion of the *financial* value of the varying inputs of management as distinct and separate from non-material satisfactions.

I have already implied that our present approach to the problem of measuring management lies in the use of personal characteristics

as predictive factors. The entire approach, at present, is an adaptation of the forced-choice rating technique developed and adopted by the U.S. Army in 1947 for its officer ratings. The technique was suggested to us by our cooperating psychologist, Dr. L. L. McQuitty, University of Illinois Department of Psychology, who commanded the army research section that worked on its development.

The new army rating is very clearly described by Dr. E. Donald Sisson, Assistant Chief of the Personnel Research Section of the Adjutant General's Office, in an article, "Forced Choice—The New Army Rating," appearing in the autumn 1948 issue of *Personnel Psychology*. Since I cannot improve by editing what he has written I shall quote directly and at some length from his article. For purposes of the present discussion I am substituting the word "farmer" for the word "officer" in Dr. Sisson's paper.

"Forced-choice rating elements are sets of four phrases or adjectives pertaining to job proficiency or personal qualifications. The rater indicates which of the four is most characteristic of the ratee, and which is least characteristic; and repeats this selection for each of the sets included. A sample set is the following:

- A. Commands respect by his actions.
- B. Coolheaded.
- C. Indifferent.
- D. Overbearing.

It is at once obvious that two of these are relatively favorable terms, and the other two relatively unfavorable. One of the two favorable terms, checked as most characteristic, gives plus credit; selecting the other gives no credit. In the same way, picking one of the two unfavorable items as least characteristic adds credit whereas the other adds nothing.

"The construction of these tetrads and the determination of the scoring key are the crucial problems in the development of a rating scale of this type. Rundquist outlined six steps in the process.

- "1. Collection of brief essay descriptions of successful and unsuccessful (farmers) officers.
- "2. Preparation of a complete list of descriptive phrases or adjectives culled from these essays, and the administration of this list to a representative group of (farmers) officers.
- "3. Determination of two indices for each descriptive phrase or adjective—a preference index and a discrimination index.
- "4. Selecting pairs of phrases or adjectives such that they appear of

equal value to the rater (preference index) but differ in their significance for success as an (farmer) officer (discrimination index).

"5. Assembling of pairs so selected into tetrads.

"6. Item selection against an external criterion and cross validation of the selected items."

In our current work at Illinois we have completed step No. 1 by securing essay descriptions on 360 good farmers and a like number of poor farmers. We have about completed the list of descriptive phrases mentioned in step No. 2, and are preparing to administer this list to a group of farmers this fall.

Turning again to Dr. Sisson's article I want to quote from his technical discussion on the construction of the forced-choice tetrads.

"As already noted, the scaling and selection of the rating elements to compose the forced-choice tetrads is the nub of the problem. The basic assumptions underlying the method can be stated as follows:

"1. Any real differences which exist between (farmers) officers in competence or efficiency can be described in terms of objective, observable items of behavior.

"2. These 'behavior items' differ in the extent to which people in general tend to use them in describing other people, i e., in general favorableness and this tendency can be determined statistically.

"3. These items also differ in the extent to which they characterize (farmers) officers at one extreme of the true scale of competence as opposed to (farmers) officers at the other extreme. The index of this difference, the 'discriminative' value, can also be determined statistically.

"4. Pairs of items can be selected such that they are equal in preference value but different in discriminative value. A rater forced to say which item is most (or least) characteristic of a ratee is thus unable to select solely on the basis of prejudice for or against him (since the preference values are equal). The rater is compelled to consider both alternatives and—theoretically at least—to do a more objective job of reporting."

With these assumptions and the outline of the steps in mind, our first task was to develop a questionnaire that would yield the descriptions we needed and such additional data as we thought necessary. Since it was impossible to assemble in one place a large enough group of farm people willing to cooperate on this study, it became necessary for the questionnaire to carry complete instructions so that data gathered from several different groups would be comparable.

Our language had to be carefully chosen to convey the intended meaning—the same meaning to all—and avoid being suggestive in any way. The opening statements were intended to stimulate interest and provide some incentive for active cooperation. Then followed a few statements asking for careful and independent work. Participants were assured of complete anonymity to remove any reticence at full and free expression. The papers were not signed or identified by the participants.

The task was divided into twelve steps to be taken one at a time and completed in order. The first step asked our participants merely to “consider some Illinois farm operators who do a poorer-than-average job of farming.” One-half of the questionnaires, in alternate fashion, began with the poorer-than-average farmers while the other half began with the better-than-average farmers. Thus we secured about one-half of our descriptions on each kind of farmer before our participants began to show noticeable fatigue. It was a wise precaution since the questionnaires took from 45 minutes to an hour to complete.

The second step asked the participant to “think of three of these farm operators (better or poorer-than-average) whom you know well enough to describe most completely and accurately.” Here the emphasis was placed upon how well our cooperators were acquainted with the people they were to describe. This step avoided the selection of those few individuals in every community who have earned reputations as good or poor farmers, but who are not well enough known by most people to get an accurate description. They were asked not to select relatives in order to avoid personal bias.

In the third step the participant was asked to “*pick the one from these three* who, in your opinion, does the poorest (or the best) job of farming.” This step was included to give us the desired range in performance from good to poor among farmers well known to the same person. This step also avoided setting up any criterion by deliberately urging the describer to “use your own ideas of poorest and poorer-than-average” (or best and better-than-average).

The fourth step asked for a series of objective data on the farmer selected in step No. 3. Included in this list were age, years in school, total land farmed, acres of this land owned, type of farming, character of the land, and the county in which the farm was located. If the describers raised questions about their ability to answer these questions they were advised to go back to step No. 3 and select a man with whom they were better acquainted.

The fifth step was really the crucial step. Here it was necessary to convey the idea of a complete description without being suggestive or introducing bias in any way. Remember that our participants were completely ignorant of the objective of the study or the purpose for which this information was being gathered. We had to avoid using such words as "behavior" and "personality" because they are not in familiar usage by farmers and would not be interpreted alike by all. So we agreed on the following simple but straightforward statements "We want you to write a description of *this man*. Tell us everything you know about him as a *man* and as a *farmer*. Please take your time and think. He may have both good and bad characteristics; describe them both. The important thing is that you describe him as completely and accurately as possible."

Steps 6 through 10 were an exact repetition of steps 1 through 5 except that where one called for a poorer-than-average farmer, the other called for a better-than-average farmer. Steps 11 and 12 were opportunities to enlarge upon the first descriptions through the aid of a list of items intended to remind them of statements which they failed to make in their original descriptions. These reminders were not handed out until the original descriptions had been handed in.

Of the 360 questionnaires filled out 18 were written by high school vocational agriculture teachers, 44 by Soil Conservation Service Work-Unit Conservationists, 13 by fieldmen in the Farm Bureau Farm Management Service, 43 by professional farm managers, 81 by freshmen and sophomore students in the College of Agriculture, and 161 by farmers cooperating in the Farm Bureau Farm Management Service. Thus all of the descriptions were obtained from people living on farms or working more or less intimately with farmers.

Whatever doubts I may have had about the ability of our farmers to become articulate with a pencil certainly disappeared when I read their essay descriptions. Among some of the rather original and poetic expressions they used in describing the poor farmers were these:

"Always fixing when he should be farming."

"More or less works around the edge of a job."

"A non-farm-management farmer."

"Hurries everything he does but getting home from town."

And the one that has particularly impressed me with its literary

style and its aptness: "Neither whiskers, nor weeds, nor uncastrated pigs annoy him."

The 360 questionnaires, or 720 descriptions of individual farmers yielded approximately 7,500 descriptive statements, phrases or adjectives. Each of these was put on an individual punch card together with all the data associated with it such as the age of the farmer to which it applied, his education, size of farm, tenure, type-of-farming, etc. Thus we have an enormous amount of data for analysis pertinent to the present problem.

Our first job was to classify each of 7,500 descriptive items and make a list of one representative item for each classification. Since this step involves a good deal of subjective judgment we decided that the job was to be done independently by three different people with a final meeting to reconcile the differences. Dr. McQuitty and I have completed our classification at this writing, and Dr. D. M. Hall, Extension Service, University of Illinois, is working on the cards at the present time. In my own classification I recognized some 328 different items applying either to job proficiency or personal characteristics.

The embodiment in one individual of functions comparable to business manager, foreman, and laborer produces a complex problem which is further complicated by the self-employed, rather independent situation of the average farmer. I anticipate that we shall encounter difficulties in scaling which may result from the fact that the population of farmers includes a wide range of personalities and attitude types that may produce a mixture of scale values for similar character traits or descriptive items. There is a possibility of a number of rather independent types among the poor farmers which may require a considerable degree of stratification on both personal and situational factors to get satisfactory scale values.

The tenure situation will require special treatment to correct for the influence of the landlord who may contribute a great deal to the apparent success of a tenant farmer, or who may actually prevent the tenant from using his best managerial ability. Still other problems confront us, such as obvious inequalities of opportunity and the matter of being "born at the wrong time", that greatly influence the degree of success in an economic venture over and above the entrepreneur's personal contribution. At this writing we have no final answers. We do have hope, the will to work, and some interesting hypotheses.

MULTIVARIATE ANALYSIS OF FARM AND RANCH MANAGEMENT DATA

JOHN A. HOPKIN
University of Wyoming

IN GETTING at this subject, perhaps I should define what I think was meant by "multivariate relationships." This might be described as a relationship wherein the behavior of one characteristic or variable (the dependent variable) is influenced by the behavior of two or more characteristics or variables (the independent variables). The problem of multivariate analysis is generally accepted as being that of identifying, isolating, and measuring the influence that each independent factor exerts on the dependent factor.

There are several conditions generally inherent in farm and ranch management data that tend to make this problem very complex. In the first place, there usually are many independent factors to be identified; secondly, in nearly all cases the influence is not linear, but responds to the law of diminishing returns within the range of a given study; third, most of the distributions are not normal but are skewed to the right. (There are several methods available for converting a skewed distribution into a normal one—but they are rather complicated and require a great deal of time.) The relationships are not additive, but are joint—that is—the influence of one independent factor on the dependent factor is not determined entirely by the size of that one independent factor alone, but is influenced by the size of another independent factor. There is also a problem of causal relationships—when a change in the magnitude of one independent variable is the direct result of a change in the magnitude of another independent variable.

My procedure, in starting on this assignment, was to review the vast amount of literature on the subject. This problem certainly is not new. The next step was to compare these several methods through the details of analysis of a given set of farm management data. Some sixty farm records taken in 1947 were used in comparing these methods. Determining the factors affecting profits was selected as the problem, as it is one that has long since been explored by Dr. Warren and others, and whose conclusions have been proven time and time again. I have selected this problem because it adapts itself so well to multivariate analysis.

It will be impossible in this brief discussion to outline the methods, or to substantiate conclusions with a detail of figures. I will merely discuss the relative merits and weaknesses of the several methods available for making a multivariate analysis of farm management data as I found them to be.

Tabular Analysis, or cross tabulation, is the simplest method available, as it is based solely upon the arithmetic average. From the standpoint of time and clerical help it is the most efficient. As the data in each subgroup are used in determining the averages of that subgroup only, and exert no influence beyond that subgroup, this method makes most inefficient use of data. For example, if there are four independent variables to be studied, and if the data are broken into three groups for each variable, it would necessitate 972 farm records to give 12 observations for each subgroup if the farms were all equally divided among the subgroups, which, as you know, would seldom happen. For most of us, this number is prohibitive.

The method offers no measurement as to how closely the factors being studied are correlated. The reliability of tabular analysis may be tested by the "t" ratio test and the analysis of variance technique for significant differences between the subgroup averages.

One of the errors of tabular analysis of multivariate relationships arose from the erroneous assumption that to subdivide farms on the basis of magnitude of size, and yield, eliminated, in turn, the effect of the one factor on the other. This was not true. There was considerably greater variation in size of farms on those whose yields were below average than on those whose yields were above average. Neither was the crop index the same for the different sized groups. This is an interserial influence that tabular analysis fails to consider. Aside from this interserial or causal influence, joint relationships can be isolated using tabular analysis. Because of its inefficient use of data, the nature of the curvilinearity of a relationship cannot be accurately determined, because the data cannot be broken into a sufficiently large number of subgroups to establish curvilinearity.

Mathematical Correlation is the technique of describing a line that most nearly fits the data being studied. The most universally used mathematical device for fitting a line is the method of least squares, which describes a line from which the deviations, when squared, will be smaller than any other line. The advantages of mathematical correlation are: (1) it makes more efficient use of

data than the other methods, (2) it measures the degree of correlation between the factors being studied, and (3) measures of reliability, and the standard error of estimate, can be computed from the calculations required for the regression equation.✓

The disadvantages of the method are: (1) it is difficult and tedious to work. For example, with just four independent factors, two pairs of which are joint, assuming the simplest form of curvilinearity, it would take 66 different series of computations as the basic data from which the normal equations could be solved; (2) the biggest weakness of this method is that the selection of the formula determines the general nature of the line—i.e., a linear equation is capable of describing only a straight line, even though the relationship may actually be curvilinear. There are many curvilinear formulas possible, from which the analyst must choose one that will best describe the relationship to be studied. Thus he pre-determines his answer a great deal by his selection of a formula. With a joint relationship this procedure is complicated further by the number of possible ways of describing the joint relationship. It may be expressed as $X_1 = b_2X_2 + b_3X_3 + b_{23}X_2X_3$, which is perhaps the simplest expression. The relationship might also be

$$\frac{X_2}{X_3}, \quad \frac{X_2}{X_3}, \quad \frac{X_2}{\log X_3}, \quad \frac{1}{X_2X_3}, \quad \frac{X_2 + X_3}{\log X_2X_3}$$

and many other more complicated forms.

Before leaving the mathematical correlation methods, mention should be made of the *Court* method for analyzing joint relationships, published in 1930. This method depends upon a mathematical rotation of the surface of cubes so that instead of averaging the values only when viewed with respect to the rectangular axes, they may also be averaged with respect to axes cutting across the surface at an angle. This method is worthy of investigation and study by the farm management analyst.

Graphic Correlation analysis is of several types. There is what I will call the formal method, which has as its starting point the mathematical linear multiple correlation, and makes a series of corrections to these lines by plotting the residuals or deviations until no further corrections appear warranted. Another method, the short-cut or *Bean* method, was developed by Louis Bean. This method assumes the general nature of the relationship by plotting a few selected observations, and then makes a series of corrections

on the assumption by plotting the residuals. This method took less than one-fourth the time required for the formal method.

These two graphic methods have much the same advantage as the mathematical correlation. They are less precise, however, and must be used with caution. If the number of cases are extremely large, they tend to lose some of their advantage of saving time and clerical labor. They do have an advantage in that they do not assume to know the nature of the relationship at the outset.

Determining joint relationship by contours. A method has been worked out by Frederick V. Waugh and others by which a three-variable surface may be smoothed directly in both independent dimensions at one time by the use of isorropic lines. With this method the nature of the relationship is not assumed at the outset, but unfolds as the work progresses. The first step is to plot the observations on a graph, with one independent variable as the abscissa, and the other independent variable as the ordinate. Thus, the location of each observation on the chart is determined solely by the size of these two independent variables. The value of the dependent variable is written on the graph beside the point where the observation falls. The joint relationship becomes evident upon inspection by comparing the location of the points whose values are approximately equal. To assist in the measurement of this joint relationship, contour lines are drawn in by inspection to most nearly represent the scale of values for the dependent value. This, of course, can be only an approximation. The deviations of the actual from the estimated, can be obtained by interpolation. It is obvious that the standard error of estimate, and the index of correlation can be only an approximation.

This method does have merit in that it is highly flexible, and saves time. It is limited to two independent variables at one time, however.

The problem of causal relationships between the independent variables. When a change in the magnitude of one independent variable is the direct result of a change in the magnitude of another independent variable, they are said to have a causal relationship. If one of the two causal factors is held constant at its average while the other factor is varied, a condition has been created mathematically which will not be likely to happen in actual practice. For example, it was desired to determine the net effect on income of feeding livestock, after the effects of size, crop yields, and labor

efficiency were eliminated by being held constant. Two arguments for feeding livestock are that it will increase crop yields and labor efficiency. Thus, to hold these two factors constant at their average while studying the effects of feeding livestock, eliminates some of the advantages of feeding livestock. It is impossible to isolate the net effect of livestock feeding on income by any of the methods mentioned thus far. However, the mathematical regression equation, *when taken as a whole*, and the multiple correlation coefficient, give the correct combined effect of the several factors studied.

With tabular analysis, a causal relationship introduced an error that was not detected when only the average labor income for each group was presented. The error was due to variation in the average values of the independent variable, when the assumption was made that they were the same. Thus, the influence of a factor was not eliminated by subgrouping, because of an interserial or causal relationship, which also contributed to unequal numbered subgroups.

In summing up my investigation of the question of causal relationships between independent variables, it must be pointed out that when a causal relationship exists between two independent factors, the net effect of one of the independent factors on the dependent factor cannot be determined. The true combined effect can be determined using multiple joint correlation, provided the correct mathematical formula is selected.

It might be well to review the *purpose* of our investigation in farm management. If the purpose is to determine the most favorable combination of highly inter-related factors, should we concern ourselves with trying to isolate and measure net effects of each factor? From the multiple joint correlation regression equation the most favorable combination of factors can be arrived at mathematically by use of the integral and differential calculus.

As might be expected, there is no one solution to the problem of which statistical method to select for multivariate analysis of farm management data. Quantity of data is one of the determining factors considered in the selection of the method to be used. Because of the paucity of data available in most farm management research, cross tabulation is of doubtful reliability for the final analysis. Mathematical correlation is too inflexible for use in the original investigation procedure. Tabular analysis, and the graphic methods should be used to explore the many possible related factors

in any management study. Those factors that appear to exert the greatest influence can be defined further and tested by the mathematical correlation methods and calculus.

My very limited investigation leads me to say that our science does not stand in need of statisticians, as such. What it really needs is farm management analysts, equipped with economic theory as a tool, and trained also in statistics. Edgar Allen Poe stated this more keenly: "To observe attentively is to remember distinctly; . . . While the rules of Hoyle (themselves based upon the mere mechanism of the game) are sufficiently and generally comprehensible. Thus to have a retentive memory, and to proceed by 'the book,' are points commonly regarded as the sum total of good playing. But it is in matters beyond the limits of mere rule that the skill of the analyst is evinced. He makes, in silence, a host of observations and inferences. . . The necessary knowledge is that of *what* to observe."¹

DISCUSSION

CARL P. HEISIG

Bureau of Agricultural Economics

These three excellent papers discuss several new approaches and techniques in farm management research. Mr. Fellows' paper on developing and applying production functions in farm management research places this technique in proper perspective. All of us are interested in increasing our knowledge of how to establish relationships between variables so prediction can be made with greater certainty. The use of mathematically derived production functions will be extremely helpful, but as Fellows points out we do not have the data available in many areas, particularly in physical input-output relationships, to derive the kind of production function that would be most useful.

Fellows rightly points out some of the weaknesses of institutional segmentation of research. This is an old problem, but progress is being made. A particularly hopeful sign is the great interest in developing balanced farming and similar programs. These programs emphasize the farm management approach—the necessity of treating the farm as a unit and obtaining coordination and integration—not only in the farm plan and operations, but also among the various specialists giving advice to farmers. These developments, however, will challenge farm management workers still further to supply the necessary economic evaluation and interpretation.

The development of standard performance rates seems to be a very useful device. Farm management workers can be in the vanguard in pointing

¹ Edgar Allen Poe, "The Murders in the Rue Morgue," *Representative Selections* by Alterton and Craig, American Book Company, New York, 1935.

out to farmers the possibilities in adoption of new technologies—rather than reporting what has happened after their adoption generally by farmers.

Mr Reiss' paper deals with an intriguing, although difficult subject of research. It is indeed gratifying to have some one tackling this difficult problem with some new and fresh ideas. The Division of Farm Management and Costs is much interested in this work, in fact to the extent of helping initiate and finance the project.

We have felt that in order to make progress beyond that attained heretofore and to take advantage of some wartime developments, a marriage was necessary between farm management and psychology. This is essentially an experimental study. Whether it is possible to identify personal characteristics in farmers or prospective farmers that will have predictive value in measuring success or managerial ability in farming is certainly open to question. But here is a new approach that offers some possibilities.

Hopkin has given an interesting appraisal of the merits and weaknesses of available methods of making multivariate analysis of farm management data. Occasionally we need to take stock of our bundle of tools and reappraise their usefulness, if for nothing more than to refresh our memories a bit. We need to give careful thought to which statistical technique is best under particular circumstances and objectives. Too many of us give too little thought in planning of projects to the most appropriate kind of statistical analysis.

Emphasis on development of hypotheses and careful attention to project design, including the development of the most appropriate statistical technique for the particular objectives—all this prior to the taking of field schedules—is certainly an essential if we are to make most effective use of limited research budgets and make the progress in research results that is expected of us.

We can go in several directions in planning our research. First, with relatively fixed budgets we can limit the number of studies made so that each will include enough cases for valid statistical treatment.

Or second, we can quit trying to make all-purpose general farm management surveys that try to cover all conceivable situations in a farming area. This means limiting the scope of studies to a few of the more important situations or variables. For instance, we can limit our sample to 80-acre dairy farms of a particular soil type, rather than attempting to cover several different sizes and soil types.

Or third, we can give more emphasis to case analysis. This has some weaknesses for some purposes, but may have far more value in the end than attempting broad-scale statistical analysis with inadequate data.

I believe we have made some progress in use of better statistical and research techniques in recent years, particularly in the direction of more precise delineation of the problems to be studied, in more careful determination and limitation of the universe to be covered in terms of the important variables, and in more careful sample design and sample selection.

These are problems, however, that need careful consideration in all of our research, and I'm sure that much more progress is possible than has been attained so far.

NEEDED NEW DIRECTIONS IN AGRICULTURAL PRICE ANALYSIS

KARL A. FOX

Bureau of Agricultural Economics

THIS paper is addressed to persons who, like myself, are primarily interested in answering specific questions about agricultural prices. I should like to separate the applied science of agricultural price analysis rather sharply from the related pure sciences of economic and statistical theory. When I speak of needed new directions I am thinking of ways in which the level of applied work may be improved and the results made more useful for purposes of prediction or policy formation.

Regardless of the state of pure theory, decisions must be made and action taken. Price support legislation, storage policy, marketing agreements and cooperative marketing programs all raise questions which involve supply and demand curves. In the absence of measurement, such questions may be answered only by hunch and assertion. Arguments over the merits of flexible price supports are partly based upon different assumptions regarding farmers' response to price. The relative merits of price support purchases and compensatory payments for different commodities depend partly upon the shapes of their demand curves. The desirability of using compensatory payments on hogs depends partly upon the closeness of competition between hogs and beef cattle. Wherever measurement of the key relationships is possible, there is a chance to improve the quality of administrative or legislative decisions.

The usefulness of such measurements will depend very largely upon the adequacy of the economic and institutional analysis underlying them and upon the appropriateness of the statistical techniques used. However, I feel very strongly that improvement in the present level of applied work does not need to wait upon *new* developments in theory or methodology. I think we can still make some advances in agricultural price-supply-demand analysis with no more elaborate theoretical tools than were available to Ezekiel, Schultz, and others almost twenty years ago. Additional insight can be obtained with the aid of economic and statistical concepts developed or popularized during the last two decades.

Successful price analysis requires a fusion of statistical technique, economic theory and specific knowledge of commodities and

markets. This is a big order for one person. Few commodity specialists have made the necessary investment in theory and technique. On the other hand, a predilection for theory is often associated with a distaste for empirical research. The striking thing about the development of price analysis in the 1920's is that it was spear-headed by men who were primarily agricultural economists, and who reached out into economic and statistical theory for the purpose of improving their applied work. However, this tradition has been greatly attenuated by sixteen years of farm programs, war and reconversion during which these men and their immediate followers moved out of price analysis or at least into positions where they had little time or incentive to publish in that field. On the basis of published work, it would be hard to identify any successors of Ezekiel, Bean, Waite, and Working who have achieved a more effective synthesis than they did of the skills and interests needed for commodity price analysis.

In my opinion, the most immediate need of agricultural price analysis is that young men with advanced training in theory and statistics be brought into contact with the practical problems of the field. In view of the increasing specialization of economic theorists, mathematical statisticians and commodity analysts, it may actually require teams of specialists under competent and imaginative supervision to fill this need.

Given the basic combination of skills and interests, there are good reasons for believing that we can improve upon the analyses of the late 1920's and early 1930's. (1) In the first place, we have longer statistical series. Whereas many of the price analyses made in the 1920's were based on pre-1914 data, we now have for most commodities about 20 years of usable data from the interwar period—roughly, 1921 to 1941. (2) Improvements have been made in our basic estimates of production, prices, and stocks, and new series on total and per capita consumption have been developed. Thus, more economic concepts now have their statistical counterparts, and errors of measurement in many of the basic series have been reduced. (3) In particular, we now have estimates of national income and related variables which are much better measures of demand for farm products than the makeshifts (such as industrial production, pig iron production or stock prices) which were sometimes used in the early 1920's.

In using these improved materials, we can avoid one of the dead

ends encountered in the early and middle 1920's, the correlation of only distantly related variables with the immediate object of obtaining a high correlation coefficient. As a rule, relationships of this sort proved highly unstable. The mere fact that such analyses did not "make sense" in terms of economic theory tended to reflect discredit upon the whole field of quantitative price research.

Really fruitful lines of development must be based upon concepts of causation or at least structural relationship. This view was strongly advocated by Sewall Wright and E. J. Working in the 1920's and early 1930's. It lies at the basis of Ragnar Frisch's method of confluence analysis and of the Cowles Commission technique. In 1934, E. J. Working stressed "the need for analysis of demand in terms of causation" . . . It is only when we combine statistical evidence in a closely knit reasoning process that we can hope to arrive at causal and hence permanent relationships between factors." This passage was quoted with approval by Tjalling Koopmans in 1937. Subsequently, Mr. Koopmans has played an active part in developing the Cowles Commission technique, which aims at the measurement of structural relationships between economic variables.

The philosophically minded may boggle at such words as causation. If our economy were really a static universe, we might satisfy ourselves with statements about the probability that a given value of pig iron production would be associated with a Chicago corn price lying within a specified interval. In actuality, the danger of spurious correlation between time series due to trends and major cycles is so great that we can hardly hope to obtain stable relationships unless we succeed in approximating rather simple and direct lines of influence which reflect the behavior of identifiable economic agents.

This approach places a great deal of emphasis upon the preliminary analysis of a problem. On a formal level it may involve the construction and simultaneous statistical fitting of complete "models." A less ambitious but highly instructive procedure is simply to draw a diagram of the various factors which seem, on the basis of observation and theory, to be involved in the problem. Starting with a central square representing (say) the U. S. average farm price of a commodity, bring in the various elements which play upon it most directly, such as farm production and stocks and dealer and processor demand. The demand of processors, for ex-

ample, is influenced by anticipations of demand from wholesalers, retailers and ultimately from final consumers. The quantity demanded by consumers is influenced by the retail price of the given commodity and to a lesser extent by those of competing commodities; also, by consumer income and other factors. As a matter of logic, such a diagram can be elaborated into a complete system of Walrasian (or Hicksian) equations. But this is merely the *reductio ad absurdum* of a useful tool.

Such a diagram, extended to not more than twenty or thirty "boxes" or variables, will lead to the conscious consideration of a good many problems which might otherwise be glossed over. What minimum time unit is necessary, in the case of a particular commodity, to average out the effect of anticipations upon the relationship between farm and retail prices? What is the maximum time interval within which current production or supply is not significantly affected by current price? Is it permissible to express farm price directly as a function of consumer income, or is it necessary to measure separately the relation of retail price to consumer income and the relation of farm price to retail price? Is it reasonable to use the index of wholesale prices of all commodities as a deflator or demand shifter in explaining the farm price of potatoes? A diagram may indicate that various components of this index enter into the explanation in such different ways that no confidence can be placed in the net regression of potato prices upon the over-all index. It may also lead to a realistic appraisal of the degree of error introduced by aggregating or ignoring certain variables, and by measuring certain coefficients or characteristics of a model independently of others.

I do not think that successful application of a causal or structural approach requires the simultaneous determination of every net relationship in such a diagram. The Cowles Commission has, indeed, worked out a technique whereby a complete model, defined in terms of five or more equations and fifteen or more "structural coefficients," can be fitted simultaneously. However, as the complexity of such models increases so does the likelihood of introducing some weak or unstable elements into the structure. Each structural coefficient represents an average relationship over the whole time period for which the model is fitted. Unless the underlying relationship has in fact been fairly stable over this period, that particular coefficient will be misleading and it may also lead

to distorted values for the other coefficients. A model which assumes the stability of each of a large number of net relationships over a twenty-year period may well imply a greater degree of economic determinacy than has actually existed. The Cowles Commission has opened up what may prove to be a very fruitful type of analysis. Its discussions of the "identification problem" and the biases which arise when the least squares method is used inappropriately have been useful byproducts. However, the published applications of the Cowles Commission technique to date have been mainly illustrative, and considerable further testing and development is needed before its place in substantive research can be defined. In the meantime, the pursuit of structural or causal relationships must be carried on largely by other means.

One line of attack is the cross-checking and comparison of logically related analyses. Most commodity price analysts in the past have looked at one product at a time. Yet it seems quite obvious that an analysis of the demand for all meat should be checked against similar analyses for beef, pork, lamb, and veal, taken separately. Analyses of retail meat prices should be checked against analyses of farm prices or Chicago prices of meat animals. Analyses of farm prices and farm cash receipts from meat animals should check out against analyses of cash receipts from all livestock products as a group. An estimated elasticity of demand for all food at retail may have to be reconciled with the estimated flexibility of U. S. farm prices with respect to the physical volume of farm marketings. Time series results should make sense in relation to family budget data or the results of consumer preference studies.

In a word, I believe that our knowledge, or hypotheses, about factors affecting farm prices will have to be based primarily upon the agreement or disagreement of many semi-independent pieces of evidence. I do not know what sort of probability statements we shall be able to make as the result of our cross-checks and comparisons. It may be useful in some cases to combine a number of separate equations into a more complicated model which can be fitted by the Cowles Commission technique. In other cases it may be legitimate to pool information from two or more equations by other mathematical processes. However, in the present state of the art, we cannot avoid nonstatistical judgments when we try to allow for recent changes in the structure of forces playing upon a

commodity. Only Laplace's "divine mathematician" could hope to fit all elements of the agricultural price system into an unambiguous set of prediction equations.

So far in this paper I have tried to make the following points. (1) We need to establish, either in individuals or in teams of specialists, the sort of combination of theoretical and factual knowledge to which the leading analysts of the 1920's at least aspired; (2) we should concentrate on a search for causal or structural relationships which "make sense" in terms of economic theory and institutional factors and which are therefore likely to be fairly stable over the time interval with which we are concerned; (3) the search for structural relationships can be aided by careful qualitative analysis of the lines and directions of relationship between variables, and perhaps by the construction of mathematical models; (4) aside from careful qualitative analysis, our main safeguard against false conclusions from individual price analyses will lie in the reconciliation of semi-independent analyses for other commodities, aggregates, or market levels. By and large, these suggestions amount to a revival and amplification of the "traditional" approach to price analysis developed in the 1920's, with progress depending in part upon the existence of longer and better statistical series than were available at that time.

However, there have been a number of developments in economic and statistical theory during the past two decades which may further enrich our applied work. One of these is the concept of indifference curves which was reintroduced into the British and American literature by Hicks and Allen during the 1930's. Even though it may not be possible to measure indifference curves empirically, I think that the concept is helpful in visualizing the relationships between competing and independent commodities and the differing effects of changes in relative prices, in incomes, and in tastes.

Theories of imperfect competition with their emphasis on product differentiation may improve our applied work by helping us to avoid sweeping generalizations about "average prices" which are not justified by the structure of the markets in question or by the substitutability of the different grades and varieties which figure in the average. The concept of cross elasticities of demand which grows out of the theory of imperfect competition may be useful

in determining the relative homogeneity of commodity groups and the permissibility of aggregating the prices or quantities of different commodities into a single composite variable.

In the field of statistical technique, Ragnar Frisch's method of confluence analysis, developed during the 1930's, should be singled out for experimentation and testing in applied work. Efficient application of Frisch's technique requires that regression coefficients be calculated by a matrix method with which few agricultural economists in this country are familiar, even though an appropriate computation scheme was published by Fred Waugh more than ten years ago. Frisch's method stems from the basic fact that when two variables are not perfectly correlated, two different regression equations are obtained by minimizing the squared deviations for each variable in turn. The structural relationship (if any) between the two variables presumably lies somewhere between the two elementary regression lines. Confluence analysis provides a routinized method of determining the consistency of correlation results when deviations are minimized along different axes and also of determining the effect of additional variables upon the net regression coefficients. Frisch's method was extensively used by Tinbergen in the statistical testing of business cycle theories (1939), and has more recently been used by the British economists Richard Stone (1945) and A. R. Prest (1949) in the field of price and consumption analysis. It is possible that the mechanical safeguards offered by this method will cause some investigators to slight the basic qualitative analysis of their problems. Nevertheless, it is a tool which deserves serious trial in this country.

One area in which radically new methods may be needed is the analysis of short-run changes in prices of perishable commodities. This area is of particular concern in the operation of marketing agreements which provide for volume and quality controls. For example, the level and slope of the demand curve in Week Number 4 may depend upon the volume and quality of shipments in Weeks 1, 2, and 3. Due to inertia if nothing else, the position of the demand curve in Weeks 5 and 6 might be affected by the position in Week 4. Thus the problem of maximizing returns over the marketing season as a whole involves the controlled distribution of the commodity between *interdependent* markets.¹

¹ This problem was brought to my attention by George Mehren of the University of California.

Care must be taken here to distinguish between shifts in the demand curves of final consumers and shifts in the demand curves of dealers based on short-run anticipations. It seems likely that anticipations will play a prominent part in farm price changes during any period which is short in relation to the normal transit-and-storage life of the commodity. The traditional methods of season-average-price analysis are probably inadequate to explain such short-term price variations. Special case studies may be necessary to disclose the rational and irrational factors that enter into the anticipations of representative dealers. Study of highly perishable commodities may also throw light on the more general problem of determining the minimum interval of time which is logically and/or statistically necessary to reduce the interdependence of successive price observations below some predetermined level.

Time does not permit the consideration of several technical problems on which new research is needed, such as aggregation, statistical deflation, and choice of functional forms. Among other things, the choice of appropriate variables to represent consumer demand has not yet been definitively treated. I should like, however, to raise one extremely practical question which faces us at the present time: How shall we adapt analyses for the interwar period 1920-41 to the requirements of prediction and control during the years immediately ahead? The trebling of national income and near doubling of the wholesale price level since the 1930's have raised the problem of extrapolation in an acute form. The requirements of extrapolation may force us to use logarithmic rather than arithmetic equations for the interwar period in many cases, and in others to use deflated rather than actual prices. Analyses based upon year-to-year changes (for example, logarithms of link relatives) may be more useful in many cases than extrapolating analyses based upon the original variables. The recent studies of Cochrane and Orcutt indicate that the first step, and in many cases the only necessary adjustment, in analyzing relationships among serially correlated time series is to transform each series to first differences. Of course, the year-to-year change method breaks down when demand shifts rapidly, as it apparently did in the case of meat and dairy products during 1948-49.

One other possibility is that the methods of sequential analysis can be adapted to choosing between alternative models in a minimum amount of time. Certainly, each new year of the postwar period furnishes us with additional information on the structure of

postwar demand. I am hopeful that we can obtain much more accurate forecasts by the pooling of prewar and postwar information than would be implied by the standard errors of forecasts from the prewar analyses themselves. It should give us some encouragement to consider that a similar problem of extrapolation also existed in the 1920's, a period during which great progress was made in price analysis.

STATISTICAL ISSUES IN PRICE RESEARCH

J. A. NORDIN
Iowa State College

AS MR. FOX has suggested, there is great diversity among the procedures currently used or advocated in the analysis of demand. The diversity exists even though all the workers may concur in thinking of the nature of our economic system on the lines of the Walrasian model, consisting of a very large number of simultaneous equations connecting all economic variables.

The diversity of procedures appears as soon as the workers try to use their common model for prediction. Unfortunately, the model is only vaguely specified, and is extremely complex. Anyone who wants to use it in clarifying social problems must accept the necessity for simplification. Wherever there is simplification, there are sources of error in prediction. Each worker will choose his own simplification, attempting to avoid the errors that he thinks can be easily avoided, and those that he thinks have serious effects on the appropriateness of social action.

Under such conditions, it is not to be expected that there will be any one procedure that ought to be considered the correct one. At least for the present, there seems to be little hope of avoiding a resort to opinion. As price research continues, there may be a consensus among workers to the effect that a certain type of error can be handled conveniently by adopting a specified technique; in such a case, the refinement can be expected to become part of the working knowledge of most researchers. In another case, there may be no feasible way of determining the relative seriousness of a group of errors; in such a case, workers may have to rely on intuition, or on a comparison of computation difficulties.

The uncertainty that surrounds our work can be seen by considering the relation between "shock" and "error" models. Assume that one of the equations of a complete economic model is the following:

$$(1) \quad \alpha p + \beta q + \gamma I + \epsilon_1 x_1 + \cdots + \epsilon_n x_n = 0,$$

where

p is the price of a good,

q is the quantity bought in a specified period,

I is the national income for the specified period,
 $x_1 \cdots x_n$ are other variables influencing the relation between
 price and quantity, and
 $\alpha, \beta, \gamma, \epsilon_1 \cdots \epsilon_n$ are unknown parameters.

The variables $x_1 \cdots x_n$ have, individually, slight effects on price and quantity. However, taken as a group they exert a significant influence on the market results.

Assume that we are unable to observe $x_1 \cdots x_n$. Assume also that we are unable to observe I directly; instead, we observe an $I^* \cdots$ a composite of I and other variables, $y_1 \cdots y_m$. Concretely, let

$$(2) \quad I^* = I + \eta_1 y_1 + \cdots + \eta_m y_m$$

where $\eta_1 \cdots \eta_m$ are unknown constants.

Suppose that we fit some function to the variables p, q, I^* . We shall have

$$(3) \quad \alpha^* p + \beta^* q + \gamma^* I^* = 0$$

where $\alpha^*, \beta^*, \gamma^*$ are the fitted constants. This expression is equivalent to

$$(4) \quad \alpha^* p + \beta^* q + \gamma^* (I + \eta_1 y_1 + \cdots + \eta_m y_m) = 0.$$

Plainly, α, β, γ and $\alpha^*, \beta^*, \gamma^*$ are different sets of numbers. They differ because (4) includes a spurious "y" influence, and because it also excludes a legitimate "x" influence. The inclusion of the "y's" represent "error." The exclusion of the "x's" represents "shock."

Presumably we can improve on $\alpha^*, \beta^*, \gamma^*$, if we take into account both types of shortcomings in our model. However, no way of doing so is available at the present time. There are ways of dealing with either "error" or "shock" separately. In choosing to use either an error model or a shock model, the worker must make up his mind about the relative seriousness of the two differences between (1) and (4). For instance, he must decide about the seriousness of imperfect reporting of statistics (error) in relation to the seriousness of the omission of a large number of variables whose individual effects on the market are slight (shock). Presumably there is no reason why all workers should reach the same conclusion on such an issue. For instance, a large part of the research that has been done at the Institute for Applied Economics, Cambridge Uni-

versity, has assumed an error model.¹ On the other hand, most of the work identified with the Cowles Commission has assumed a shock model.²

Issues

Simultaneity: It seems to be necessary to deal with at least one demand curve and at least one supply curve, if we are interested in finding the demand curve for any product. We observe prices and corresponding quantities. Presumably every price-quantity point is the intersection between a demand curve and a supply curve. If we are to predict future intersections, we must attempt to understand the demand and supply curves.

If we wish to improve our knowledge of demand curves, it is important that we should not exaggerate the amount of information contained in just the price-quantity observations. To every price-quantity point there corresponds an infinite number of demand and supply curve combinations that could have intersected at the given point.

If we were limited to price and quantity observations, we could never "identify" a demand curve or a supply curve—we could never say about a particular equation: "There is reason for preferring this equation to every other equation, as an approximation to the unknown equation that describes demand conditions." Fortunately, we can observe other relevant statistical series. Under favorable conditions, we can construct curves having particularly strong claims as preferred approximations to demand and supply curves. In at least some problems, the limited information method, perhaps supplemented by complementary procedures, seems adequate for "identifying" demand curves.³ There is good reason to hope that some combination of current methods can provide a reasonably good analytical basis for policy decisions affecting agricultural prices and outputs.

The limited information method is called a simultaneous method, because models on which it is used include at least two equations,

¹ Richard Stone, "The Analysis of Market Demand," 108 *Journal of the Royal Statistical Society* 286, 1945; A. R. Prest, "Some Experiments in Demand Analysis," 31 *Review of Economics and Statistics* 33, February 1949.

² M. A. Girschick and Trygve Haavelmo, "Statistical Analysis of the Demand for Food: Examples of Simultaneous Estimation of Structural Equations," 15 *Econometrica* 79, April 1947.

³ T. W. Anderson and Herman Rubin, "Estimation of the Parameters of a Single Equation in a Complete System of Stochastic Equations," 20 *Annals of Mathematical Statistics* 46, March, 1949.

to be solved simultaneously for certain parameters. The number of equations must equal the number of endogenous variables. Any variable appearing in the analysis is endogenous unless it is either a disturbance (a composite of a number of variables that are not observed directly) or a predetermined variable (one that can be regarded as given for the purpose of the problem being investigated.) We shall undoubtedly treat as endogenous variables the price and quantity of the good whose demand curve we want. If any other good is particularly closely related to the given one in the minds of buyers or sellers or both, we may include equations for the demand and supply of the second good.

Clearly our decision to include or exclude a certain equation involves some judgment. If we proceeded in a certain extreme fashion, we should attempt to deal with supply and demand equations for several grades of cotton. We must expect disagreement on the feasibility of certain degrees of fineness in our distinctions among grades. On the other hand, we may agree that a model used in finding the demand for butter ought to include equations relating to oleomargarine.

Another difficult problem relates to the treatment of social aggregates, such as the national income. Suppose that national income is included in the demand equation for the commodity in which we are interested. Must we deal with an equation accounting for the determination of national income?

In the past, many workers have treated such aggregates as given functions of time, and therefore not to be determined simultaneously with the price of an individual product. On the other hand, Girschick and Haavelmo, in their distinguished study of the demand for food, deprecate such treatment: "We could always split up total consumption into small sub-groups by a sufficiently detailed specification of the various types of consumer goods. Obviously, such a regrouping could not alter the fact that changes in the total consumer expenditures have a direct effect on income, income being the sum of consumers' expenditures and investment expenditures. We must therefore assume that income . . . depends to some extent on the random shifts . . . in the demand for food."⁴

It appears unwise to make a statement as sweeping as that of Girschick and Haavelmo. We must always base our judgments partly on the nature of the specific social problem on which we are

⁴ Girschick and Haavelmo, *op. cit.*, p. 88.

working. Presumably we can agree that a complete description of the operation of our economy would include an account of each market's effect on the national income. But we cannot yet escape from the galling constraint to accept approximations in place of the truth. When we allocate the resources available for an analysis of a particular social problem, it is not obvious that we must always concentrate on getting a relatively accurate representation of the process of determining national income. The price of a group of grades of cotton may have little effect on the national income; accordingly, we may choose to focus our attention on the relations among the prices of the several grades. On the other hand, if we deal with something that we call the market for food, perhaps we must follow Girschik and Haavelmo in writing an equation describing the formation of national income.

However, there is some reason to think that our work in the near future can be most fruitful if we restrict ourselves to small groups of commodities. There is danger that in dealing with agricultural aggregates we may obscure the problems connected with the allocation of resources within agriculture. Successful treatment of broader social problems may have to wait until someone has put aggregative economics into a more satisfactory condition. Before we include aggregative equations in the determination of demand curves, we ought to ask ourselves whether, for instance, there is not considerable justification for Howard Ellis's statement about one of the aggregative relations: "... The consumption function seems to resemble the Holy Ghost: a derogatory attitude toward it is the ultimate sin, but precise information about it is hard to come by."⁵

Setting Up the Simultaneous Model: It is possible to start our statistical work by assuming that we know what variables belong in each of the equations that we propose to use. If we have at our disposal an economic theory that seems to have passed its critical tests well enough for our purposes, there is a fairly strong reason for using the equations appropriate to the theory. But if the theory has not been tested—that is, if it is still properly called a hypothesis—we can only say that we *assume* the validity of the hypothesis. The validity of our findings depends partly on the validity of the economic theory used.

In many cases it will be necessary to choose among economic

⁵ H. S. Ellis, "The State of the 'New Economics'," 39 *American Economic Review*, 476, March 1949.

hypotheses. Stone⁶ and Prest⁷ have used confluence analysis in selecting variables for their demand equations. They assume that every observed variable consists of a systematic part (which may be related to the other variables in the demand equation in question) and a disturbance (consisting of variables like the "y's" in equation (2) above). The systematic part of an observed variable may improve our ability to explain other observed variables; the accompanying disturbance has the opposite effect. Confluence analysis is a method of determining whether the systematic effect predominates over the disturbance effect—and thus whether it is wise to include the suspect variable in the equation under consideration.

If variables are to be selected by the use of confluence analysis, and then parameters are to be estimated by the use of the limited information method, we must remember that the former assumes an error model, while the latter assumes a shock model. In terms of equations (1) and (4) above, the problem can be stated as follows: when we are deciding whether to include the variable I^* does the unrecognized presence of variables $x_1 \dots x_n$ impair our judgment to such an extent that confluence analysis ought not to be combined with the limited information method?

Apparently, no analysis of this problem is available. But there is the following reason for thinking that confluence analysis ought to be retained: the unrecognized presence of $x_1 \dots x_n$ spoils our prediction whether I^* is included in our model or not. Let us make the comparatively mild assumption that each x is uncorrelated with I^* . Then it appears reasonable to expect that failing to consider the " x 's" will have the same effect on our prediction, whether I^* is included or excluded. If this conclusion is valid, the fact that we shall later use the limited information method does not rule out the use of confluence analysis in construction of the model.

In general, there is need for considerable work on the subject of testing hypotheses in economic problems. Suppose a group of hypotheses deal with demand and supply equations. By what Cohen and Nagel call the "deductive development of hypotheses,"⁸ we can "deduce" from a given set of equations some predictions about

⁶ *Op. cit.*

⁷ *Op. cit.*

⁸ Morris R. Cohen and Ernest Nagel, *An Introduction to Logic and Scientific Method*, New York, Harcourt, Brace, and Company, 1934.

future prices and quantities. We shall probably not be able to predict these prices and quantities exactly. But a hypothesis that predicts better than any other over an extended period of time has a relatively strong claim to be used in further prediction.⁹

When we limit ourselves to "predicting" past prices and quantities, it is difficult to choose among hypotheses. If we restrict ourselves to polynomial equations, we can make certain choices. If series x is being used to predict series y , we may choose between a first and second degree equation by observing the improvement in "fit," in relation to the loss of a degree of freedom. But no such procedure is available when we compare the results of two prediction equations, only one of which is a polynomial. It is not legitimate to compare the degrees of freedom in the two cases.

This degrees-of-freedom difficulty seems unavoidable as long as we deal with "fit." But when we use two equations to predict observations that have not been used in estimating the parameters of either equation, it appears that we need not concern ourselves with degrees of freedom. Since the predicted values have not been used to determine the predictions, we may be able to compare closeness of prediction directly.¹⁰

Some variant of this procedure may deserve experimentation. For instance, we may want to go back to using the first $\frac{2}{3}$ of a set of series in predicted certain values in the last $\frac{1}{3}$.

⁹ It is assumed that each hypothesis tested is suggested by some such process as introspection—that it is not chosen by selecting statistical series at random.

¹⁰ However, it might be necessary to refuse to predict when the values of the variables used in predicting fall outside the range of values used in setting up the estimation equating.

USING PRICE RESEARCH

GEORGE ALCORN
University of California

I HAVE been asked to discuss the use and acceptance of statistical price analyses that have been made in the agricultural field in California by farmers, farmers' organizations, and others for whom the material must in the end be intended.

First, what about the farmer and price research? In most cases he receives only the "answers" of price research in the form of general outlook information. Where prices are not established or supported by government, his price information is most likely to be only qualitative.

Farmers' marketing organizations for handling California specialty crops request and use considerable statistical price analyses as a guide in their operations. What we are talking about here and now is not market information, but statistical price analyses, which measure quantitatively price changes caused by or associated with changes in certain variables. Some of these organizations' particular need for price analyses arises from the fact that their commodity is only marketed during a very short period in the year. In some instances the whole of the crop must be sold at once in a market which has had no transactions for a year. Their market cannot be tested periodically, nor is price focused sharply for them as it is in the case of commodities sold on highly organized exchanges. We might parenthetically say, nor are the commodities they handle designated commodities in Price Support legislation, which, of course, would set up some mark with respect to where prices might be.

Farmers' cooperative bargaining organizations selling processing fruits and vegetables, perhaps, use more statistical analysis in their price problems than most other groups. Their problem is peculiar in that price for their product is usually a negotiated price. Prices are established only once a year for a short season. In between seasons, no price exists. Where should price be established this season? Who knows? That is the problem for the negotiators, and they want what scientific help that is useful—to their ends. We are told by these farmer bargaining organizations that they use these price analyses in crystalizing their thoughts about the market.

Grower organizations handling fresh fruits and vegetables do

not have the same kind of need for price analysis as do organizations selling to processors, who must sell the whole of the crop at once on a cold, unknown market. In the case of citrus, price analyses have long been used by grower organizations to assist in determining a desirable utilization of the season's crop. What is needed and what is lacking, however, is some price analysis to guide action during periods within a season.

Industry Marketing Control Committees. We have in California a number of marketing agreements and orders operating under both federal and state statutes. While the federal and state government officials alone have the power to make the regulations, they do receive and study the recommendations of industry advisory committees. We should point out that with the exception of milk, prices themselves cannot be regulated. However, prices can be greatly influenced by other powers, such as control of supplies and sizes, market stimulation, etc.

What use, then, do these industry control committees make of price research? Usually it is necessary to prepare quite a little analysis of price behavior for presentation at the hearings to institute a program. A survey of opinion indicates that by and large most committees do not use detailed price analyses after programs have been instituted.

Processors, handlers, and their organizations use some price analysis and, in addition, spend considerable funds in obtaining other relevant data. Price analyses are used by several companies as a guide in sizing up the market situation and, in some instances, in determining offering prices to producers. However, factors other than statistical price analysis may and do determine "offering prices." Price analysis is also used by some companies for current situation appraisal, as well as for determining bases for future operations. Some in this group expect to place more reliance upon statistical price analysis as times "become more normal" in this post-war period. Some say they used price analysis to a considerable extent in the prewar period.

In conclusion I might make the following observations:

- (1) In California statistical price analyses are used more by growers organizations and market control program committees than by individual farmers.
- (2) Statistical price analyses for farmers' organizations are perhaps most useful in selling commodities to processors.

- (3) Results of statistical price analyses thus far appears less useful and bargaining more difficult where there are multiple utilizations of the product.
- (4) Farmers' organizations and handlers want more price analyses whether they actually use them or not. They expect them to be more useful as more post-war data become available.
- (5) For general farm audiences the "case" method of presentation receives good attention.
- (6) The author of involved mathematical price analysis designed for some immediate operating problem should himself present the analysis to the operating group.
- (7) Industry groups make little or no use of price analysis to precisely maximize returns. Available data are not exact enough to be definitely sure that returns can really be precisely maximized by any course of action.
- (8) A byproduct of price research is the recognition of necessary and more complete data. Perhaps more cooperation is needed between persons gathering statistics and the analysts.
- (9) It appears to me that the areas of usefulness and the limits of price research are not well staked out. Some folks place more reliance in price analysis than is justified, others are perhaps unduly scornful.

MAKING PRICE RESEARCH USEFUL

J. CARROLL BOTTUM
Purdue University

IN COMMENTING on this subject I would like to point out that. (1) in the early stages we asked and were offered too much in our price analysis research; (2) our price analysis research has not made its full contribution during the past decade and a half; (3) the need for the contributions of price research has increased many fold; (4) what we need is basic quantitative economic measurements which the operating forecaster and policy maker may use; and, (5) we should not delay our activities in this field waiting for methods which will give us the same degree of accuracy that may be obtained in the natural sciences.

Price research has not kept pace with the growth in price forecasting or price policy making. We have continued to expand work in agricultural outlook and in agricultural price policy without quantitative price research making the contribution to these activities which it should and could make.

In the 1920's we expected too much. We were looking for a statistical formula to predict prices of individual commodities. Some statisticians in their enthusiasm gave it to us. When economic conditions changed and the relationships and weights assigned to the various factors were no longer applicable to the new economic conditions, the formula forecasting fell into disrepute. With this set-back, caution arose concerning any complicated mathematical approach to price research.

Analyses need to be made by individuals or groups of individuals who are fully familiar not only with statistical procedure but also economic theory and a full knowledge of the characteristics of the commodity involved. We, also, need to make this data available in understandable form to the many individuals working in the outlook and policy fields.

We have before the nation proposals to make direct payments to farmers for the amount the free market price of the commodity averages below the announced support price. Empirically derived supply and demand functions are needed to complete economic models which will provide estimates of the effects (including costs) of such a pricing program under assumed or historic conditions.

These are not mythical problems, they are altogether too real. Discussions are being carried on and decisions are being made without the full benefit of quantitative price analysis research.

If we turn to the outlook field or where price information is used as a guide to private operations where do we find adequate statistical data showing supply and demand relationships? In making an appraisal of the hog outlook, for instance, one really sets up a model, although most of us do not think of it in these terms. We have reasonably good estimates of hog farrowings. Let us assume that we arrive at a forecast of an acceptable level of disposable income. With such a disposable income, what would be a statistically reliable demand function for pork products? Marketing costs are readily predictable a year ahead. The prices paid for pork may thus be calculated and in turn the prices for hogs. I recognize that we have changing demand schedules for pork, but let the forecaster or the operating outlook worker have the knowledge of how demand has operated under various situations.

The point I'm trying to make and to emphasize is that the econometrician should provide the basic pieces of price data which the operating agricultural forecaster and the agricultural policy maker needs to make a quantitative analysis of any current situation. The outlooker and the policy worker must choose what price data or model pertains to the situation involved. The econometrician should be interested in building a large base of fundamental data which those working directly in the applied economic fields may use. I am inclined to believe that there is much useful price data that has been prepared and is being used by individuals working in the price forecasting field that might profitably be published and made available to many others.

Our price research resources call for the use of the most simple, least time consuming techniques. Complex models—by the very fact that they are models and that no one is a “divine mathematician” are simplifications that must be judged with the intuition called experience. We must keep in mind that if they are to be valuable they must be used by others. The use of the simpler methods also leads to a more critical view of the results. In some instances it has almost appeared that the object was to keep the presentation involved. There is less tendency to swallow a brass doorknob if it isn't so elaborately wrapped.

In price analysis we need to break away from the natural

sciences' 95 to 99 percent limits of probability as the key to whether findings are significant. We should not wait until we have reached these limits. There are too many changes with time which the statistical approach probably can never measure, to strive for too high a degree of statistical accuracy in the price area. It is like striving to put a razor edge on a soapstone. The fundamental relationships of the factors used are too unstable to justify too high a degree of refinement.

One cannot discuss the subject of making price analysis research more useful without mentioning the need for more complete statistical data. This includes not only the gathering of data but also making it available in a usable series. We have made much progress in this area; nevertheless, there are still many gaps. The marketing processes should be more fully described. We need more data on governmental action programs, which not only include dollar data but also bushels and acres. We also need more regional information.

Because much of our price analysis is national in scope, I should like to raise the question—do we not need more coordination in price research? Far be it from me to propose that all price research be included and stereotyped into one great project. Yet, maybe we could make more progress and make more fully available the necessary information if we took a partial lesson from the approach used in the development of the atomic bomb. Perhaps the alternative is enlarged activities in the Bureau of Agricultural Economics, closely geared to the more specialized activities carried on in the States.

MEASURING THE INCOMES OF FARM PEOPLE

ERNEST W. GROVE AND NATHAN M. KOFFSKY

Bureau of Agricultural Economics

WE KNOW something about the incomes of farm people—but not nearly enough. We know approximately what their total income has amounted to in any given year; and from the number of persons on farms, the number of farm workers, or the number of farm operators, we can compute simple arithmetic averages of their individual incomes. But we know very little about how the total income is distributed among farm families. We can also compare averages of farm income with corresponding averages of nonfarm income. But we are not sure just how “comparable” the figures really are.

This lack of detailed knowledge with respect to the distribution and comparative level of farm income arises in good part from the indirect methods that must be used in its estimation. Treating agriculture as though it were a single large firm, we estimate its gross income, its production expenses, and its net income from a wide variety of data on farm production, marketings, prices, and costs that have been collected primarily for other purposes. The method yields aggregates only, in terms of current values prevalent at the farm; and while the results are probably fairly reliable for what they purport to be, they are nevertheless inadequate for some purposes.

For the general purpose of indicating the comparative well-being of farm people, there are three major inadequacies. (1) Lack of state estimates of net farm income, (2) an absence of any satisfactory basis for comparison with nonfarm incomes, and (3) a dearth of acceptable data relating to size distributions. The method used in developing the national aggregates is also adaptable to state estimates; and a start has been made in their preparation. Thus, the only difficult problem in the case of state estimates is that of trying to do the job with insufficient resources.

In the areas of comparison and size distribution, however, some conceptual and statistical problems are as yet unresolved. It is the purpose of this paper to indicate something as to the nature of these problems and to provide a brief summary of the tentative results obtained in several recent attempts at their solution.

Problems of Comparison

In any attempt to compare the absolute levels of farm and non-farm incomes in terms of data now available, three principal questions arise. (1) How complete are the respective totals in their coverage of income? (2) What is the difference in their purchasing power? and (3) What is the most satisfactory unit or basis for comparison?

Completeness of coverage has to do chiefly with the fact that many people receive income from both farm and nonfarm sources, so that a simple average comparison of farm and nonfarm incomes may give distorted and misleading results. The problem may be handled by including all sources of income on both sides of the comparison, or by limiting the comparison to those groups that have but a single source of income. The latter course probably presents more statistical difficulties than does the former in the present state of our knowledge; and it is subject to further objection in that the scope of the comparison is defined in terms of the incomes to be compared.

Other factors to be considered under the heading of coverage are the intangible elements of income associated with the comparative advantages and disadvantages of farming as a way of life. Few would deny that farm life provides a psychic form of income that is not generally enjoyed by urban populations. Is this psychic income wholly or partially offset by economic disadvantages that are not reflected in our income data? The question is not amenable to statistical treatment; but it should not be forgotten in the final analysis.

The question of purchasing power has to do with (1) differences in the composition of commodities and services that go to make up comparable levels of economic well-being on the farm and in the city, and (2) differences in the cost of similar items in the two situations. Paradoxically, the very fact of large differences increases the difficulty of measuring them accurately; and the basic index-number problem becomes especially acute in this case. The theoretical issues involved are well known, and need not be developed here; but the most important practical problem, namely the valuation of nonmoney income, deserves a brief mention.

With the possible exception of members of the armed forces, farmers are the only large group to receive a major portion of their income in kind. Farm-produced food and fuel wood consumed

directly in farm households is ordinarily valued at cost in terms of prices actually received for the sale of similar products. And the occupancy value of farm dwellings, inseparable in the market from the rental or sale values of farms as a whole, is also imputed as something approaching opportunity cost. How are these items to be treated in measuring differences in purchasing power or "cost of living"?

One possible solution is to eliminate them completely from the monetary comparison. That is to say, income on both sides of the comparison could be defined as net money income after deducting all expenses for food, fuel, and housing. The comparison would then be in terms of income over and above that required for some of the basic necessities of life; and if desired, a supplementary comparison of the quantity and quality of the latter could be made in terms of physical instead of value units.¹

On the other hand, if these imputed, nonmoney items are retained in the monetary comparison, the cost-of-living analyst must answer some difficult questions. Retail prices of food normally average about twice as high as prices at the farm which are used in valuing home consumption. And the rental values assigned to farm dwellings have been only about a third as large, on the average, as rents on nonfarm dwelling units. How much of these spreads can be considered as representing real price differentials? And how much is due to differences in quality of the commodities and services being priced? The problem is particularly difficult in the case of rental values because housing available on the farm is frequently of an entirely different kind from that available in the city.

The third major question in any comparison of farm and non-farm income is the appropriate basis for that comparison. That is to say, the aggregates of income, however adjusted, must be reduced to units of comparable size and quality. Should the comparison be in terms of income per person in the total population on the basis of farm or nonfarm residence? In terms of income per worker on the basis of occupation? Or in terms of income per family on the basis of either residence or occupation? Because of the relatively large numbers of children and older people on farms,

¹ Some proposals of this general nature were tentatively suggested by Dorothy S. Brady in a paper presented at the 1949 meeting of the Conference on Research in Income and Wealth.

the large proportion of unpaid family workers in the farm labor force, and the relatively large size of the average farm family, the choice among these or other alternatives obviously will have a material effect on the results to be obtained.

Another question in this connection is whether the comparison should be in terms of simple, nation-wide averages of income, or whether farm and nonfarm incomes might better be compared within each region or state. The latter basis would give results somewhat more favorable than the former to the farm side of the comparison, because a large proportion of the farm population and only a relatively small part of the nonfarm populations are in the south where incomes in general, both farm and nonfarm, tend to be lower than average.

It is no part of the purpose of this paper to try to provide any final answers. But it may be worth while to summarize briefly the results obtained in two recent and tentative studies which attacked these problems on a nation-wide basis.²

In one case, 1941 data on prices paid for family living by farmers and by urban wage earners, obtained primarily from the study of "Family Spending and Saving in Wartime," were combined into weighted index numbers representing the average price differential between farm and city. The 1941 average net income per farm operator from farming was then adjusted downward to eliminate an estimated average value of unpaid family labor other than that of the operator; and the result was compared with the average annual earnings of factory workers in the light of the price differential previously established. The conclusion was that the purchasing power of farmers' incomes so adjusted averaged about 25 percent less in 1941 than that of urban factory workers. Similar calculations for 1945 were also made in this study, using price data translated to reflect the wartime situation; and the results indicated approximate equality of purchasing power as between farm operators and factory wage earners in that year.

In the other study, a series of rather complicated adjustments were applied directly to the BAE data on per capita farm incomes to achieve rough purchasing power comparability with nonfarm

² One of these studies appears as "Farm and Urban Purchasing Power" by Nathan Koffsky in Volume 11 of *Studies in Income and Wealth*, Conference on Research in Income and Wealth, National Bureau of Economic Research, New York, 1949, pp. 153-178. The other is summarized in the "Comment" of E. W. Grove appearing in the same volume, pp. 212-215

per capita income. The results were then adjusted to allow for differences in the regional distribution of the farm and non farm populations and in the average size of the family in the two groups. It was concluded that, for the United States as a whole, real incomes of farm and nonfarm families in the same general locality averaged about equal in 1945, but that a disparity of at least 25 percent prevailed in most prewar years.

In neither of these studies was the comparison based on a functional analysis of income. Total incomes were compared, in other words, without any special attempt to distinguish returns from land, capital, labor, and management on either side of the comparison. In other respects, however, the two studies differed considerably in their approach to the problem. In one case, the labor income of the average factory worker was compared with the average farmer's composite returns on his capital, labor, and management, but exclusive of any income from nonfarm sources. In the other case, average total income of nonfarm families from all sources was compared with the corresponding average total income for families living on farms.

Because of these differences between the two studies in the basis for comparison, their respective conclusions are not strictly comparable. And both, it may be noted, were based on income data that have since been revised. Yet they tend to reinforce each other in pointing to the general conclusion that during the last three or four years farmers may reasonably be considered to have achieved something approaching income equality with the rest of the country.

But this "equality," if real, is only in terms of nation-wide averages of income; and we are not yet able to say very much about income relationships in individual states. Such limited data as are available suggest that during the last few years farmers in certain parts of the Western and North Central regions of the country may actually have been a good deal better off than nonfarmers in those areas. And at the other end of the scale, particularly in certain parts of the South, it seems equally likely that farmers have remained at a substantial disadvantage even during the general farm prosperity of recent years. It is possible, therefore, that average equality for agriculture has been achieved in part at the expense of greater relative inequality *within* agriculture. But firm conclusions on this score are not possible in the present state of our knowledge.

Distribution by Size

Thus far we have been concerned with totals and averages of farm income, and with problems of comparison. But even if we had complete and up-to-date data of this kind, which could be interpreted precisely from a comparative standpoint, the absence of size distributions of income would still prove to be a serious lack. The comparison of average incomes needs to be supplemented with information as to how many of who get how much.

Commonly cited in this connection are the Census of Agriculture distributions of farms by value of sales or by total value of product. These distributions are useful, but they are incomplete. We need distributions of farmers' net income as well as their gross income. And we also need to know how the distribution of farm families by size of net farm income is changed when income from nonfarm sources is taken into account.

The Bureau of Agricultural Economics has done a good deal of work along these lines in recent years. It has recently completed some preliminary estimates of size distributions relating to the income of farm-operator families in 1946. But this is another field in which it is difficult to obtain conclusive answers, and we are not yet ready to say that our results are the best that can be achieved. The preliminary findings were reported to the Conference on Research in Income and Wealth earlier this year, primarily for the purpose of obtaining a technical review of the statistical adjustments applied to the original survey data. As a result of this review further investigations of the data and refinements of procedure are now in process; and the distributions may be materially revised in the near future.

Nevertheless, the results obtained so far seem fairly reasonable, and some of the main findings are not likely to be very much affected by any future revisions. So the following summary of methods and results can be presented with little fear of contradiction in the final analysis.

The distributions were based largely on data relating to farm income and expenses for the calendar year 1946, collected in the Enumerative Survey of Agriculture in January 1947. More than 14,000 usable schedules were obtained on gross cash farm income and about 3,700 usable schedules on production expenses. As in other recent income surveys conducted by other governmental agencies, the BAE survey was characterized by underenumeration of farms and underreporting of income. Underenumeration was not

a serious difficulty because sufficient control data were obtained in the survey to permit expansion of the sample to the number of farms reported in the 1945 Census of Agriculture, using three major size-of-farm groups. It is to be noted that the underenumeration was largely in the smaller farms; this is primarily a reflection of the difficulty of identifying them as farms according to the Census definition.

The heart of the difficulty in constructing reliable size distributions of farmers' incomes lies in the severe underreporting of income which apparently is characteristic of farm income surveys. Receipts are generally understated, partly because of failure to remember the many transactions involved in the farm enterprise during the year, and also because of reluctance to disclose income data. These biases operate with greater force on the reporting of farm operators' income than on the reporting of income by most other occupational groups. Wage earners, for example, generally have fixed rates of earnings, easy to remember and report, and also relatively easy to check. In the companion survey of nonfarm incomes in 1946, conducted by the Bureau of the Census, more than 90 percent of total urban wages and salaries was accounted for in contrast with only about half of total net cash farm income in the farm survey. Under such circumstances, the necessity of adjusting the original distributions is self-evident, especially when comparisons are sought between farm and nonfarm groups.

After expansion to the 1945 Census number of farms, the survey accounted for 72 percent of the aggregate BAE estimate of cash farm receipts, 91 percent of estimated total production expenses, and only 49 percent of net cash farm income. There was a fairly consistent pattern in the extent of underreporting by regions, implying that the sample was rather uniform in coverage for different parts of the country. It is noteworthy that the value of sales as reported in the 1945 Census of Agriculture represented an understatement from the BAE aggregate of approximately the same percentage as occurred in the 1946 survey. Furthermore, the Census distribution of the value of sales is quite similar to the distribution of gross cash farm income obtained from the survey, particularly when allowance is made for the generally higher level of income in 1946.

The BAE totals of gross income, production expenses, and net income are themselves subject to errors of estimation; and the question naturally arises as to the propriety of adjusting the income

distributions to reflect aggregates which are not guaranteed to be correct. Yet the preponderance of evidence is on the side of adjustment. It is a characteristic of income surveys to underreport income, and the underreporting is usually greatest in the case of the self-employed, whether farm or nonfarm. In the 1946 surveys, nonfarm entrepreneurial income was underreported by about the same proportion as farm income. It should also be remembered that the Census of Agriculture is an income survey insofar as it relates to the value of sales or of total product; and as such it is subject to the limitations and biases of any income survey.

The relatively good reporting of farm production expenditures—91 percent of the estimated BAE aggregate—provided the opening step in adjusting the survey results. After raising all production expenses proportionately to reflect the BAE estimate, the corresponding gross cash farm income was determined by means of a relationship between gross cash income and production expenses at each income level determined largely from other sources. The survey covered the nonfarm income of farm-operator families, but excluded nonmoney income. By a series of cross-tabulations, however, and with the aid of data from other sources relating to the nonmoney income from farming, the following distributions were developed which reflected the BAE aggregate estimates: (1) Gross cash income from farming, (2) net cash income from farming, (3) net cash income from farm and nonfarm sources combined, and (4) net total income from farm and nonfarm sources, including nonmoney income from the farm.

In all cases, the distributions after adjustment are more unequal than before adjustment. This is because the available evidence indicated that most of the "missing" farm income belonged in the higher income groups, on the basis of the relationship between cash farm income and production expenses at those levels; and the adjustment was accomplished accordingly.

However, the greatest interest attaches to the lower income groups which were relatively little affected by the adjustment. In the distribution of gross cash farm income, the original survey indicated that 33 percent of all farms had gross cash incomes of less than \$500. After adjustment, the percentage was lowered only slightly to 29 percent. For *net* cash farm income, the original distribution indicated 33 percent with *negative* incomes, and the adjusted distribution 30 percent.

At first glance, the indication that almost a third of all farms had

negative net cash farm income in 1946—an unusually prosperous year for agriculture as a whole—may seem unreasonable. But after reference to the distribution of gross cash farm income, to the standard definition of a farm, and to the distribution of income from nonfarm sources, it begins to appear quite reasonable.

As already noted, nearly a third of all farms had gross cash farm incomes of less than \$500, a proportion that is substantially confirmed by the value-of-sales data from the Census of Agriculture. Approximately two-thirds of all negative net incomes fall in this group with relatively low gross farm income. It should be emphasized that for the most part these farms are not commercial operations. Some are primarily country residences. Others, supplemented by income from nonfarm sources, provide living from the farm in noncash items. The tremendous importance of nonfarm income to this group may be illustrated by comparing its average size at each level of net cash farm income. For those farm operators with negative cash income from farming, the average nonfarm income was \$1,700. At levels of net cash farm income above zero and ranging up to about \$6,000, income from nonfarm sources becomes substantially smaller, averaging around \$500 more or less at those levels. At still higher levels of farm income, nonfarm income again becomes increasingly larger in absolute terms, though it remains a relatively small part of total income at those higher levels. But the most significant point in all of this is that negative net cash farm incomes do not actually mean an excessively low level of total income for any substantial number of families who fall in that group.

Inventories are another matter worth mentioning in connection with negative cash farm incomes. One of the principal gaps in our data relates to the effect of changes in inventories on the distribution of income. The survey was confined to cash items, and did not obtain any information on inventories. But we know from a study of farm-account records in Illinois that some commercial farmers fall in the negative net cash farm income class because they are building up inventories. On the other hand, some farmers were in the higher cash income classes because they were selling out of inventories. Although no precise estimates can be made, the inclusion of farm inventory changes might have reduced considerably the number of farms in the negative income group.

For purposes of comparing the income distributions of farm and nonfarm families, it is appropriate to include for the farm-operator

family all the income it receives—cash farm income, income from nonfarm sources, and nonmoney income received from the farm in the form of food and shelter. It would also appear appropriate to value the food consumed on farms at retail prices to farmers. If all this is done, then the shape of the income distribution for farm-operator families in 1946 turns out to be much the same as that for nonfarm families.

* * *

It was concluded earlier in this paper that the over-all average incomes of farm and nonfarm families have probably had about the same real purchasing power during recent postwar years. And the further conclusion has now been reached that their incomes were probably distributed by size in somewhat the same fashion. But it does not necessarily follow from these two tentative and independent observations that the purchasing power of income was the same at each of the corresponding size classes in the two distributions. Much more detailed studies would be necessary to establish any such correspondence.

Three frontiers in farm-income research have been briefly considered here, namely the development of state totals, the comparison with nonfarm income, and the construction of size distributions. Some pioneer work has been done on all three. But so far the work on any one has been largely—and necessarily—independent of that on either of the other two. If and when the work shall have progressed to a point at which answers to all three can be combined, then, and not until then, will we really be able to measure the incomes of farm people.

REFLECTIONS ON POVERTY WITHIN AGRICULTURE*

THEODORE W. SCHULTZ

University of Chicago

A Summary

The setting of this paper is the American scene, concentrating on the long run and abstracting from sudden changes and fluctuations that occur in the short run. The simplifying empirical propositions on which this paper stands are as follows:

1. The differences in the level of living among communities were not as great at the time people were pioneering new areas or at the time industrialization began as they have become since then.
2. Significant differences have emerged within agriculture not mainly because of a deterioration on the part of those communities in which people are now living under conditions of poverty, but largely because of the increases in per capita income that have been realized by other communities.
3. These gaps, consisting of differences in level of living, are basically the consequences of the way in which the economy of the United States has developed and not primarily the result of any original differences in the cultural values or capabilities of the people themselves.

Each of these propositions is meaningful in that an appeal can be made to empirical experience in determining its validity. The third proposition is central and crucial. The observation is made that the physical characteristics of land are passive in the poverty problem. The drift of prices is also in a passive position.

Can economic progress bring about increasing disparity of income? It could not if we were to take the classical conception of economic progress; that is, increases in aggregate income under conditions where per capita income tends to remain constant. This is the Ricardo-Malthus-Mill, "Dynamics of Political Economy." It is based on two rates of change: (1) power of production and (2) power of population with the power of production in the position of the limitational factor. Given this conception, communities do not diverge in per capita income.

A broader formulation of economic progress consists of increases in aggregate income with changes in per capita income unspecified, except that no community is made worse off. This view includes the Ricardo-Malthus-Mill conception as a special case. The principal analytical problem becomes that of specifying the *conditions that are necessary* for a disparity in per capita income to emerge.

The economic history of Western Europe since 1650 suggests that the advances in technology and in economic organization usually ascribed to the industrial revolution gave rise to (1) a greatly increased aggregate production, (2) a marked increase in per capita income generally in Europe despite the fact that the European population multiplied five times from 1650 to date, (3) an increasing disparity in per capita income between

* The full text of the paper presented at Laramie will appear in the *Journal of Political Economy*, vol. LVIII, February, 1950.

Western Europe (certainly up to World War II) and those parts of the world that had not benefited from the process of industrialization, and (4) conditions which impeded migration of non-Europeans to Europe, a development that would have brought about factor-price equalization to human agents between European and non-European communities had it occurred in sufficient numbers.

We then examine the conditions that are necessary for increasing disparity in incomes to occur. The effects of capital accumulation are indicated. The main analysis, however, concentrates on the following three sets of conditions:

1. Conditions that determine the proportion of a population that contributes to income. The ratio of contributors to non-contributors is affected by changes in composition of population associated with economic progress, changes in continuity of employment and the specialization permitted by division of labor that emerges with economic development, and by the differences ascribable to income measurement and to income accounting.
2. Conditions that determine the abilities of a population to produce. This approach calls for a classification of abilities. The abilities that can be acquired are of central interest. A brief survey is then made of the (1) process by which capital is "invested" in human agents; (2) amount thus invested; and (3) effects of this investment on productivity of a population.
3. Conditions that impede factor-price equalization. Economic progress requires exceedingly large transfers of human agents. An instructive special case is a pre-industrial demographic type of population under conditions that do not necessarily require any trade or factor movement to attain factor-price equalization. Transfer of factors is, however, necessary under advanced industrial demographic type (the Samuelson exception is noted) in order to attain factor-price equalization. There remains the difficult problem of determining the comparability of typical human agents in pre-industrial and advanced industrial demographic communities. It appears that we are dealing with essentially comparable factors with two types of exceptions. One of these occurs when long systematic training for specific skills is required and the other when ability to adapt in the short run is insufficient.

There are basic cultural impediments to factor-price equalization. These involve sociological considerations having costs aspects. For society, the gains to be achieved from paying the costs of reducing these cultural impediments are greatest when these costs are non-recurring for any migrant.

DISCUSSION

ERVEN J. LONG

University of Wisconsin

Professor Schultz' major thesis, developed out of his analysis of the causes operative in creating disparities among economic levels of different

farm communities, is that poverty in rural areas is due to their having been by-passed in the processes of industrial progress. This analysis serves at least one very important purpose. It removes the responsibility for poverty from the individuals so affected, and fixes it upon the public. This justifies work on the problem by economists as being in the public interest, and support of their proposals, if sound ones be found, a public responsibility.

But there are certain methodological implications of the argument which I find quite uncomfortable. They find their clearest expression in the series of comments on what Professor Schultz refers to as "research concentrating on land." However, since I believe, along with him, that his conclusions on this point are necessary logical implications of his formulation of the problem, the following comments should have a bearing upon a much larger array of implications of his argument.

The question I should ask is: what kind of conception of causation can help remove or diminish poverty in agriculture? Implicitly, it seems to me, Professor Schultz' argument conceives of causation as being much like immutable impersonal forces. As we try, following this conception, to unravel the skein of causation involved in the creation of poverty in agriculture, we trace it back through human affairs, halting somewhat arbitrarily on the developmentary processes of the country's economy. We could have, with equal logical precision, traced the pattern of causes by way of the unequal geographical development of the country, back to the uneven disposition of mineral and other natural resources. We thus need come to no logically imposed halting place until we find the explanation of our problem in the beneficence of the gods or the orneriness of the devils, as best suits our disposition. This conception of causation, as the working out of impersonal forces sweeping human affairs on to their destinies, serves quite well in transferring responsibility from the individuals affected to the public. For it is becoming almost a norm of our public morality that we do not allow individuals to suffer unaided the full brunt of disaster-bringing impersonal forces outside their control. For such a purpose, it doesn't matter much where we stop in our tracing out the path of causation, provided only that it is sufficiently far removed from the individuals we are interested in helping.

But the broader problem of finding ways of improving the level of living of the poorer people in agriculture makes more exacting demands upon our method. A conception of causes to be relevant in the problem and to have power in its solution must have its basic focus not upon present circumstances and their antecedents, but upon present possible courses of action and their probable consequence. This consequence-grounded conception of causation has been the uniquely American contribution to logical theory. In logical theory, the pragmatic conception of a cause is that which can be isolated and when brought under control will bring about a desired reconstruction of the situation under study. In the words of the great Chicago philosopher G. H. Mead, "Generally it (i.e. cause) is some condition which can be changed in order to bring about a different result."

If our analyses are to lead to acceptable and workable formulations of policies to follow in reducing rural poverty, they must be couched directly in terms of alternatives available in the situations in which poverty occurs,

and are only indirectly concerned with the "underlying causes" by which such poverty is explained. This consideration leads me directly to the conclusion that our contribution to the solution of the problem of rural poverty will come principally from intensive and systematic inquiry into the potentialities inherent in those situations in which poverty exists. This implies community and area studies bent on exploring the full array of available alternatives open to the poor people living in them. Especially it implies a study of local social and economic processes for an attempt to locate those strategic points at which specific public action can be most effective. (A study recently published in *Land Economics* of a very poor northern Wisconsin community revealed that most national programs designed to serve the general interest as depression remedies actually worked against the long-run interests of the people in the community.)

These public actions might include such general things as encouraging migration to other communities, development of new industries, better balancing of factors of farm production, and a rationalization of the relationship between institutions and the resources already in use. This, as I understand it, has been the principal objective of land economics research. Most such research worthy of the name has concentrated on the way in which land is incorporated as *uses* into the economic organization of the area in question. Far from being unable to reveal causes as Professor Schultz contends, they have, I believe been among the most useful of inquiries revealing causes—in the meaning of "causes" that I have sketched out, i.e. warranted clues to significant social action for relieving the communities' poverty.

It is true that land as such plays a passive role; but the way in which land is incorporated into the economic organization of a community is one of the really dynamic facts of rural life—just as the way coal and iron ore deposits, or isolation-imposing rugged terrain, are caught up in and give differential direction to the developmentary processes of our country's economy. I refer again to the northern Wisconsin community mentioned before. Built upon a combination of agriculture and forestry as the economic base, the institutions of the community took form and solidified. Line fences and farmstead locations defined the scale of operations; legal and political institutions of private property defined the mode of economic organization; custom, habit and culturally acquired tastes made the people immobile and unimpressed by the call of better opportunities elsewhere. This process set the stage for great distress when the forests were depleted and the rich, thin top soil gave out. Analysis of these processes provides, I believe, the only source of clues to procedures to follow in improving the situation. Neither the terrific internal pressures of a disintegrating community economy during the depression, nor the external wartime pull of the people into military and industrial employment, left any significant decline in the number of people residing and trying to make a living in the community. No doubt similar circumstances of poverty induced by maladjustment in land uses—the rigidifying of institutions in situations demanding their flexibility—could be recounted for most important poverty-ridden areas in the country.

I certainly agree with Professor Schultz that agricultural economists

have contributed too little to the solution of poverty in agriculture and that this is not due primarily to coercive political pressure. But I cannot believe that they have neglected the study of rural poverty because, accepting the prevailing folklore, "they do not believe that poverty is an important social problem." I believe, rather, that we have neglected study of the problem because our basic methodologies—the hidden major premises of our research—have been such as to prevent our making powerful advances on the problem.

I have developed at some length the case for intensive investigation of local economic processes. This intimacy of insight into farmers' experiences was achieved in those empirical farm management studies in which more or less agricultural economics was born. But their purposes of improving farmers' judgments in the conduct of their private businesses led to the forging of methods of inquiry adapted to deal with the limited structure of alternatives open to individual farmers, but not adapted to encompass the broader array of alternatives open for public action.

At the other pole, we have seen a great deal of vitality emerge from the application of economic principles of theoretical equilibrium to the problems of agriculture. But this methodology, too, proves inadequate in dealing with the problem of poverty. This is the message we get from the fact that policy proposals repeatedly mention the problem of rural poverty and then issue an honest disclaimer of any important contribution to its solution. This I believe testifies to the inadequacies of the method rather than to the disinterest of the economists.

Why these inadequacies? First, this type of approach serves to define the solution of the problem in terms of a theoretical norm having little reference to the problem as it exists. This flows from the fabrication of this norm (i.e. the theoretical model) from such basic abstract postulates as pure competition, rationality of action (within a narrowly defined meaning of rationality) and perfect mobility of factors of production, including labor. The direction thus given to our analyses of present situations of poverty is to point them toward this completely abstracted, hypothetical state of affairs as being a "solution" to our problem—a state of affairs defined by a system of pure ideas, untested except for their logical consistency, a society without institutions, an economy without organization. Of course, we economists do not actually operate in that way; our minds are too dialectic to follow our methods to their logical conclusions. But some such vague perception of the implications of our methods leads us to detour when we ride theoretical analysis up to the problem of rural poverty. Second, human energies are released and directed into the economy principally by the operation of social processes. In large part, the supply and availability of labor as a productive agent is a by-product of social organization. (This I hope has been demonstrated in a research bulletin on *The Labor Foundations of Wisconsin Family Farms*.) Systematic inquiry into the processes by which such energies take form and are channeled into productive uses is only indirectly aided by a method of formulating the problem which abstracts from their existence. The point we must avoid overlooking is that labor is embodied in people, and the use to which labor is put depends upon the myriad decisions of the individual persons

involved. All that we know of the processes of personality development leads us to the conclusion that the person, and therefore the decisions he makes, is really a function of the social situation in which he builds his personality. Among many people, even poverty itself is held as a value. They perhaps do not think so. But their personalities are so much a function of their social habitat that their decisions, both deliberative and habitual, made out of a craving for what John R. Commons has called "the security of even injustice and poverty," lead to a continuation of the poverty in which they live.

Policies for dealing with these by-passed cells of our social economy must, unless we follow authoritarian procedures, work their way out through the free decisions of the people involved. An understanding of the processes of acculturation which give the particular character to these decisions is indispensable to the formulation of such policies. These processes, being distinctly strategic to the solution of an intensely economic problem, fall thereby directly within the province of economic investigation. We should not, through too critical use of the theoretical-equilibrium method of approaching our problem for analysis, beg this strategic area of investigation by covering all individual action under universal assumptions which give highly particular meanings to rational conduct and to the nature of individual choice.

DISCUSSION

HERMAN M. SOUTHWORTH
Council of Economic Advisers

I think we can be heartened by the papers presented here. The progress of farm income research described by Dr. Grove, and the preliminary estimates that he so tentatively reports, suggest to me that we are on the threshold of obtaining a much better quantitative description of the problem to which policy must address itself. And the insights provided by Professor Schultz in the synthesis that he has developed can, I believe, help us substantially in broadening our future policy approaches.

Legislatively, the time is ripe for a shift from price support over to income support as the basis for major farm programs, if only an acceptable formulation of our income objective can be provided.

Grove's discussion of the effects of making income comparisons within geographic regions is highly relevant to Schultz' analysis. The fact that farm-nonfarm disparities are so greatly reduced when viewed region by region supports the thesis that the basic disparities are between regions rather than between agriculture and other industries.

In one sense, Schultz reduces the phenomenon of poverty in agriculture—defined to include only inter-community disparities—to a problem in economics of location. In another sense he broadens it to typify the whole process of the industrial revolution, and, in effect, takes it out of the realm of agricultural economics. I find his thesis a rather convincing over-simplification, that presents an important class of disparities in farm incomes in a perspective that should be helpful in our efforts to understand this problem.

I should like to throw into the discussion a few policy proposals that

would seem at first sight to have the support of Schultz' analysis. I should not like them to be taken as proposals that I myself would advocate without qualification, since they obviously involve considerations going far beyond the scope of this discussion.

1. The support of farm income through price programs, that now occupies the center of policy consideration, is not designed to overcome poverty in agriculture as Schultz defines it.

2. Schultz places major emphasis upon positive action to overcome the cultural impediments that keep people from migrating from backward to progressive communities. Such action might include:

a. Much greater emphasis upon industrial and commercial, as versus agricultural, vocational education in rural schools in the "pre-industrial" communities

b. The bringing of other modern community services and facilities to such areas, as a measure designed to reduce the unfamiliarity of their people with urban modes of life

c. A program somewhat analogous to that of the Farmers Home Administration, but designed instead to help families that cannot make a decent living from farming to establish themselves successfully in urban employments.

It is not hard to dream up programs like these. The difficulty lies in envisioning how to carry them out without an objectionable amount of Federal paternalism.

3. We might make greater progress by abandoning efforts to deal with agricultural poverty as a *farm* problem and concentrating rather upon measures to reduce the discrepancies in *general* economic development between regions. Where the impediments are too great to moving people out of the "preindustrial" communities, should we not seek instead to bring industry to these communities?

4. I am also tempted to infer from Schultz' paper some support for the Employment Act of 1946, by which my own agency came into existence. The promotion of "maximum employment production, and purchasing power" for the whole United States involves extending to all parts of the country the economic development that Schultz describes as having by-passed many, especially agricultural, communities.

DISCUSSION

JOHN W. WHITE

University of Arkansas

Mr. Grove, in his paper entitled "Measuring the Incomes of Farm People," presented in a very excellent manner the fact that some pioneer work has been done on three frontiers of the farm income measurement problem. The three income measurement frontiers listed by Mr. Grove were the development of state totals, the comparison of non-farm income, and the construction of size distributions.

I have referred to Mr. Grove's paper for the express purpose of emphasizing the point that according to his criteria we have not really measured farm income. Thus, what basis other than generalizations do we have for assuming that poverty exists in agriculture? Professor Schultz assumes that it does exist. I concur, but where? To what degree? And why?

I find no real basis for disagreeing with Professor Schultz's statement

that "differences in level of living are basically a consequence of the way in which the economy of the United States has developed." However, I do believe that Professor Schultz's presentation falls short of pin pointing actual trouble spots in given agricultural communities whether of high or low level of living.

In order to focus attention on the actual problem of poverty in agriculture and to examine some of the more plausible suggestions for solutions to the problem, I would like to take up a few examples.

In the fall of 1944, under conditions of short labor supply, the superintendent of a Southern experiment station found it necessary to haul labor to be used in farm and experimental tasks from a fringe area near the station. Monk Murphy, about 50 years old, was one of the laborers thus recruited. An investigation revealed that Monk lived in a tie-slab shack and had made an investment of \$8 in the construction of the shack. A nice four-room bungalow was available near the experiment station at a rental below the cost of transportation. When asked if he wished to move near the station Monk gave several delaying answers one at a time each good for one week's delay. The first answer was that he could not afford to lose what he had in his house; the second, that he must wait until one of a flock of six hens hatched a setting of eggs, the third revealed that his wife was afraid to move out on a paved highway for fear a car might run over their six year old son.

Finally Monk agreed to move and unloaded his furniture and placed it on the porch of the four room bungalow, which was equipped with good screens, a good water pump and a sanitary outdoor toilet. He came to see the Superintendent and asked if he might place his bed, cook stove, heating stove, dining table and other necessities all in the front room with the explanation that he and his family did not need the other rooms. Thus, Monk set up housekeeping in his new environment.

Even though he was paid each Saturday, it was necessary to advance money about Wednesday or Thursday of each week. If he bought groceries on Monday he did so on a charge account. Monk was a good tractor driver, if someone kept the tractor in repair, saw that it was filled with water, oil and fuel and greased at proper intervals.

By and by Monk failed to see that any good could come from actually working. The station Superintendent found it necessary to discharge Monk. Monk moved to a nearby town and started living in another shack in the town slums.

A more hopeful case is that of Cecil Smith. Cecil, about 30 years old, was a capable farm laborer who had at one time grown rice and cotton as a share cropper. Cecil finished the eighth grade and his wife was a high school graduate. He wanted very much to give his two children a chance to attend school. Cecil was a skilled tractor operator and could with a minimum of supervision do a very satisfactory job on almost any farm task. It was impossible for him to accumulate capital to be used in developing skills for industrial work, for the purchase of equipment to use in operating rented land or for the purchase of a farm. Cecil's major hope or best outlook is to purchase a small farm in a good neighborhood with access to churches, schools and good roads.

Our third example is John Smith, about 40 years old, with a wife and four children. He possessed a debt-free upland farm of 80 acres with 50 acres in cultivation or tillable pasture. Since markets were not available for fruit, truck, dairy or poultry products, his major source of cash income was the production from about 15 acres of cotton. Roads, schools and churches were poor in John's community.

Would a price policy guaranteeing 90 percent of parity for John's cotton solve his problem or alleviate his poverty? I doubt if it would—of course, it might take John longer to starve to death with a 90 percent support price for cotton.

John may need more capital for use in increasing the size of his business. Perhaps this should be supplied on a business basis by the government. Part of the increased capital should be used to purchase mechanical equipment to go with the increased size of business. Public research could contribute much to John's efforts to raise his level of living. A vigorous research program aimed at the development of improved crops, irrigation, proper land use and most profitable combination of enterprises would be helpful. Good local, state and Federal government programs to improve roads, schools and other public services would help. Perhaps John's children should be given an opportunity to prepare themselves for non-farm employment.

Professor Schultz concludes in his paper that society could achieve a *very considerable* gain by taking positive actions (providing the costs are non-reoccurring) to diminish the adverse effects of cultural impediments which influence disparities in income and contribute to the causes of unequal incomes between communities. This conclusion calls for consideration of the double problem of how economic progress could be promoted in low level communities and how we could eliminate or substantially diminish obvious cases of poverty in both high and low level communities.

I would like to leave with you a number of questions which I believe must be considered in dealing with this problem. These questions are:-

- (1) Could the problem be solved in large part by individual farmers through the application of all the techniques available to them?
- (2) Could the problem be solved partially through better education, and through improvement in roads, churches and similar institutions?
- (3) Could the problem be solved partially through a continued and more vigorous program of research and application of such research?
- (4) Could the problem be solved partially through public expenditures for drainage and flood control?
- (5) Could the problem be solved partially through greater industrialization in low income areas and through a better balance between agriculture and industry?

Any solution to the problem of poverty must take into account minority and racial groups in the area concerned. The racial problem is of vast importance and is extremely complex. Is it possible to legislate equality all across the board? The racial question deserves the considered study of our best students. To the extent that poverty exists in Southern agriculture, it is interwoven with the racial question which complicates most of the efforts which might contribute to the solution.

INSTITUTIONAL CHANGES AFFECTING THE AGRICULTURAL OUTLOOK; THE AGRICULTURAL PERSPECTIVE

KENNETH H. PARSONS
University of Wisconsin

ANY attempt in one brief essay at evaluating changes in the basic institutions which affect the outlook for agriculture must be highly selective. We have chosen to concentrate our comments upon changes in two major institutions, general farm organizations and the judicial interpretation of farm legislation.

I count myself among those who use the term "institutions" sparingly; it is a term of many meanings. It is used most often by economists as a blanket term to cover whatever is left over as an unexplained residue after a mechanical analysis has been pushed to its limits. Institutions in this view are conceived of as impediments to the free and full play of economic forces, as the source of inertia in adjustments, stickiness in prices, etc. Institutions are viewed as slowing down the economic mechanism much as long grass chokes up lawn mowers. As I see it, this conception proceeds from the analytical postulate of viewing the economy as a mechanism, presumably governed by mechanical laws which we call forces—forces being equivalent technically to something unknown outside the mechanism.

Obviously, if one is to comment on institutional changes with any systematic reference to economic thought, he must have a conception of an institution which both has some positive and specifiable content, and is relevant to economic investigation. In America, we have had at least two major efforts to formulate systematically a conception of economics which actually incorporated the investigation of institutions into the body of general economic analysis.

One of these was the creation of Thorstein Veblen. He ultimately reduced an institution to a habit of thought, which he conceived of as being a rather natural growth from our habits of work. One might call this a psychological conception of an institution. This viewpoint is to be found at its best, I think, in *Imperial Germany and the Industrial Revolution*.¹ This study, written before the first

¹ Originally published as, Thorstein Veblen, *Imperial Germany and the Industrial Revolution*, The Macmillan Co., New York, 1915.

World War, presented an amazingly accurate forecast of the major European developments since that time. The key, I think, is to be found in the enormous social consequences of "the way we think" about social questions—our habits of thought. Surely, there has been a profound change in recent decades in the habits of thought among our people regarding agricultural policy.

John R. Commons worked out a quite different approach to economics, which is also called institutional. In his analysis, he conceived of an institution as "collective action in control, liberation, and expansion of individual action."² In this general viewpoint, the economy is viewed as a created social organization. Commons investigated many forces of collective action, including public administration, industrial government and trade unions. His *Legal Foundations of Capitalism*³ will likely stand as the greatest published monument to his investigational genius.

In a very profound and yet very different way each of these men was attempting to rise above the limitations of a purely mechanical systematic analysis in economics. All major policy questions are concerned with institutions, with social organization. Public policy formation in a huge democracy such as ours requires the participation of countless pressure groups, along with all the branches of government. Unless economic analysis comes to grips in some fundamental way with the structure of the relevant social action, it can have only very limited influence in the shaping of agricultural policy.

I shall not try to conceal my own inclination to build upon Commons' viewpoint in the analysis of economic institutions. For purposes of this comment I am going to interpret changes in institutions as being equivalent to changes in organized collective action. This includes the conduct of both farm organizations and public officials in the execution of public policies.

Any attempt at evaluation of the effects of changes in institutions carries with it implicitly the idea that we can deliberately and of our own volition give direction to economic affairs. The directing is done through organized effort, through a revision of the working rules by which social activity is organized. The great economic problems of our time have their roots in our elementary

² See his *Institutional Economics*, The Macmillan Co., New York, 1934; and *The Economics of Collective Action*, scheduled for publication in the fall of 1949 by The Macmillan Co.

³ The Macmillan Co., New York, 1924 and 1939.

institutions. We have developed an economic system with vast aggregations of economic power, within a system of property relations designed originally for an era of handicrafts. A laissez-faire philosophy of government in our time leads to economic instability, gross inequalities, and a free hand for economic power.

The changes in farmers' attitudes toward government and their renewed faith in the possibilities of public action, are symptomatic of our times. No one, I think, would claim that we know precisely what to do. It is quite clear to most of us that the new situations require new procedures in social organization. In the most fundamental sense the outlook for agriculture is dependent upon what we do in social and economic organization. The outlook therefore is not a matter of discovering the determinate outcome of mechanical economic forces but rather of anticipating the consequences of deliberate conduct. In the broad view even production and resource utilization are by-products of the social (including economic) organization, for the simple reason that both are consequences of human ingenuity and volition applied to mere matter.

I

As we turn to the discussion of the significance of changes in institutions it is necessary to stake out some particular time span for consideration, preferably a period which might reasonably be called an epoch. And even at best such interpretations can be no more than the beginning general hypotheses for a systematic investigation into the facts of the matter. We shall look back to the approximate close of the first World War, and then attempt an evaluation of present directions by projecting our interpretations about an equal distance into the future. This gives us some rough markings from which we can take our bearings.

In the early twenties, the Grange had a membership of about half a million persons. The Farmers Union had about a hundred thousand and the Farm Bureau about three to 400 thousand members. Each of these organizations was at a different period of its career; the Grange was well along on the gradual climb in membership from the slump in activities of the early eighties; the Farmers Union had dropped from the early flush of members from 1910 to 1920; and the Farm Bureau was in a period of gradual decline which ran from 1921 to about 1934.⁴ Altogether about one million

⁴ Data on membership in farmer movements from David Edgar Lindstrom *American Farmers and Rural Organization*, The Garrard Press, 1948, Champaign, Ill., Part III, pp. 161 ff.

farmers belonged to these movements in the early 1920's.

There was no striking change in membership until about 1940. By 1946, the Grange reported 750,000 members; the Farm Bureau more than a million (1,128,259), and the Farmers Union about 140,000. This gives a total of more than two million members, more than half of which were in the Farm Bureau.

We have the phenomenon of an increasing membership during times of unparalleled prosperity. It has been observed frequently that the growth of farm organizations has represented something of a spontaneous protest of inarticulate but distressed farmers who found themselves helpless as individuals. There is strong evidence in the history of farmer movements to support this thesis.⁵

If one were to investigate the why of this great increase in membership during recent prosperity, he would likely find that this reflects a growing uneasiness on the part of individual farmers regarding their helplessness as individuals in a world increasingly dominated by the great forms of collective action: corporations, labor unions and political parties.⁶ We are undergoing, I believe, a profound change in farmers' habits of thought on this point, and many group efforts contribute to it, including the AAA and the Soil Conservation districts, and membership in their marketing and purchasing cooperatives. One might say that a new class consciousness is developing among farmers; new in the sense that it centers on a newly acquired conviction not only that something can be done by farmers collectively about economic policy matters, but that if they do not work together they will be lost in the shuffle of power groups in the economic order that is in the making.

The recent growth in farm organizations may also reflect changes in the structure of farm organizations themselves. They are acquiring professional secretaries and trained staffs. I do not see how there could be any alternative if the organizations are to deal adequately with the problems that a national organization faces which attempts to contribute to both policy formation and general supervision of the many cooperative and educational endeavors within the province of a contemporary farm organization.

This professionalization of the organizations may be very significant. At best the participating "dirt" farmers will be able to

⁵ See for example, R. L. Hunt, *History of Farmer Movements in the Southwest, 1873-1925*, Dallas, Texas, 1936, pp. III and 142; Solon Buck, *Granger Movement*, Harvard Press, Cambridge, Mass., 1913.

⁶ See John R. Commons' forthcoming *Economics of Collective Action*, The Macmillan Co., 1949.

give only general direction to organizational policies, and even then much would depend upon the willingness of the officials to be so advised. At best also, the directors of the organization will find themselves much like public administrators with a "civil servant" problem in the sense that they will be dependent upon the technical interpretations supplied by their staffs. There are all degrees of possible variation from this optimum. Not the least of the difficulties of organizations in the matter of professional personnel, one may suppose, is the reluctance of agricultural economists to accept employment which might brand them as special pleaders for a pressure group. When an organization arrives at the paid secretary stage the officers take on a considerable management function, speaking for the group on crucial policy questions.

The decline in the importance of face-to-face relationships and the rise to power of a professional leadership group is part of the natural development of organizations. But it opens up the possibility of greater conflicts between the membership and the leadership, an even more likely prospect among farm organizations than among those representing either big capital or labor. Labor organizations have long concentrated on the security of the job; they are now pushing out into politics to supplement, safeguard and expand their job status with more general securities. Big business can concentrate on keeping the restrictions off "free enterprise." But general farm organizations must expend energy in countless places on the economic front, to "protect farmers" by fighting something of a defensive rear-guard action in a triumphant groupistic industrialism.

Farmers have little economic power, even with the present extent of organization. Labor unions and corporations may proceed toward their economic objectives, without active government support, or even in defiance of government. But economic programs for farmers must be details in general political programs. Representatives of farmers must engage continuously in making alliances on specific issues over which there is room for genuine differences in judgment. In a general way organized agriculture is agreed that some kind of national agricultural program is necessary, including at least minimum price supports. Whether farmers as a prospective small minority will continue to be successful in working out the political strategy necessary to achieve such programs is an open question.

Organized agriculture is caught up in larger struggles over which

farmers have little control. The central figures in the great struggles of today and the years ahead are surely as Professor Commons has observed, capital, labor and political parties. Among the general farm organizations only the Farmers Union is openly friendly to organized labor. It is in the cooperative field where the fundamental conflict between capital and labor hits organized agriculture the hardest.

If one attempts to look ahead for two or three decades, what consequences may be anticipated on this capital-labor front that are of major concern to agriculture? I do not see anything except industrial civil war in which farmers might alternate between choosing sides and attempting to remain neutral, except as we develop a new conception of the public interest in private affairs. The outlook is not as dreary as the remark might imply, simply because we are already making that transition. In an age where the employment, inventory and investment policies of our huge corporations can and do materially affect the level of prosperity in an economy, conduct on such matters cannot be considered wholly a private affair. Similarly with labor, it is clear that there is a limit to the extent of strikes that can be tolerated, and correlatively the wage demands that public opinion can reasonably support. On the farm front it is easier for farmers to serve the public interest in their private efforts in economic matters. They can do little else, excepting as they waste the resources upon which the public is dependent. The general principle here is to see that private and public are not contradictory and conflicting purposes. It is at bottom a question of how, when, and whether the private interest also serves the public interest.

Farm organizations also face a whole host of delicate problems in politics. So far, the politics of the organizations appear to be compounded of geography and economics. But farm organizations have not entered openly into politics in recent years as have labor organizations. Organized labor has not only decided to use its political power as a supplement to its economic power, it is predominantly in the Democratic camp. However, the political situation among organized farmers is somewhat chaotic. The Grange operates in predominantly Republican territory. But we have recently been treated to the twin spectacle of having the Farmers Union territory go Republican with a president who has staunchly supported the social legislation of both the New Deal and the Fair Deal;

while the officers of the American Farm Bureau have taken on a fight over the Brannan plan as an early sequel to an election where midwest farmers' votes shifted to the Democrats.

If one can draw an interpretative inference from this political jumble it would seem to be about this: among interest groups only labor approaches the strength required to challenge a political party. With political parties being necessarily so powerful in the years ahead, farmers are likely to place fundamental reliance upon them, and for reasons quite independent of farm organization policies.

II

Twenty-five years ago the fight over the McNary-Haugen bill was nearing a climax. The Farm Bureau had just endorsed the effort. A feud was on between Mr. Hoover, then Secretary of Commerce and the Secretary of Agriculture over the jurisdiction over marketing work. The outcome, as you know well, included the passage of the McNary-Haugen bill by Congress and its successful veto by President Coolidge. As a part of this same struggle, the B.A.E. was "reorganized" with H. C. Taylor moving on to other fields.⁷

The history of agricultural legislation since that time is so familiar to all of you that I shall not take your time to comment extensively upon it. But there have been some significant developments in the judicial interpretation of legislation with which we may not be equally familiar.

Agricultural economists were forcibly reminded of the existence and power of the U.S. Supreme Court in the Butler case⁸ in 1936 which demolished the production control and processing tax features of the first AAA. The majority held in this case that agricultural production was a matter of state concern, and was not included among the powers delegated to the federal government. The marketing agreements authority of the AAA was not affected by this decision. Since that time the AAA has taken a swing toward conservation, but the drift of events has kept pushing this program back toward price supports, acreage controls and marketing quotas.

The authority of the federal government to regulate market transactions in agricultural products and fix prices seems thoroughly

⁷ See Orville Merton Kile, *The Farm Bureau Through Three Decades*, The Waverly Press, Baltimore, 1948, Chap. XI, "The Battle for McNary-Haugenism."

⁸ U.S. vs Butler, 297 U.S. 1 (1936).

established, provided only that due process of law is observed and delegation of legislative power is avoided. The leading cases in this area at present are those involving the regulation of fluid milk markets under federal order in New York City and Boston; the Rock-Royal and Hood cases.⁹

The critical question in the Rock-Royal case was whether Congress had violated the federal constitution by delegating legislative authority to the executive in the office of the Secretary of Agriculture. The majority held that no such delegation was involved. The court noted the general purpose of the Agricultural Adjustment Act to establish parity prices and included in their opinion the statement of purpose familiar to all of you.¹⁰ The court recognized also the particular provisions of the law for calculation of the parity price of milk but observed that: "This price cannot be determined by mathematical formula but the standards give ample indications of the various factors to be considered by the secretary."¹¹

The general rule which the court accepted in dealing with "questions of economic adjustment" was stated as: "In dealing with legislation involving questions of economic adjustment, each enactment must be considered to determine whether it states the purpose which the Congress seeks to accomplish and the standards by which that purpose is to be worked out with sufficient exactness to enable those affected to understand these limits."¹²

The court compared the Agricultural Adjustment Act with the former NIRA, which it disposed of in the famous *Schechter* case. The court noted that the purpose of the AAA was "to restore parity prices" and that the "terms of the orders were limited to specific provisions, minutely set out."¹³ On the contrary the declaration of policy in the NIRA was couched in the most general terms including "to eliminate unfair competitive practices, to promote the fullest possible utilization of the present productive capacity of industries, to avoid undue restriction of production (except as may be temporarily required), to increase the consumption of industrial and agricultural products by increasing purchasing power, etc."¹⁴ The significance of this comparison will be evident if it is recalled that the NIRA was declared unconstitutional on this spe-

cific question, namely the delegation of legislative authority.

The general conclusion with respect to the Court's stand on the delegation of authority is clear: where the Congress indicates with sufficient exactness the purpose of legislation and the methods by which that purpose is to be worked out, the Secretary of Agriculture is considered to be merely carrying out the indicated will of Congress.

As I study these cases two inferences emerge as of major concern to our discussion today. One, the power of the federal government to regulate and fix prices is established solidly, provided the procedure does not violate the constitutional provisions of the separation of powers and honors due process of law. But this suggests the question, just how specific does the price formula have to be to avoid delegation of authority? It is impressive, to put it mildly, how the court fastens onto the concept and formulae for parity prices. Now we have in this association heard a great deal of criticism of parity prices. Several members have given attention to alternative price criteria, notably forward prices. The question arises as to whether the court could, or would, find that a price support program based upon forward prices would qualify under its general rule for legislation on economic adjustments, namely, that the "standards" by which an exactly stated purpose is to be worked out are stated "with sufficient exactness to enable those affected to understand these limits."¹⁵ The proposed forward price program includes (a) the granting of authority to an administrative agency to determine and enforce (as minima) authoritative equilibrium prices, and (b) equilibrium prices are defined in the technical economic terms of ideal prices which would equate marginal costs and marginal returns in agricultural production.¹⁶ If one takes the Rock-Royal case as the criterion, I doubt whether the forward price proposal could be drafted with sufficiently obvious content and exactness to meet the constitutional test on delegation of powers on any issue of regulating prices.

In two cases subsequent to the Butler case which invalidated the major part of the first AAA the government's right to enforce production control regulations has been clearly established.¹⁷

In the first, a North Carolina case on tobacco, marketing quotas

¹⁷ *Milford vs Smith*, 307 U.S. 38 (1938), and *Wickard v. Filburn*, 317 U.S. 111 (1942).

were accepted by the court as falling completely within the congressional authority under the interstate commerce clause, as the procedure for making allotments was spelled out so as not to "confer unrestrained arbitrary power on an executive office."

In *Wickard vs Filburn* the court appears not only to have sustained marketing quotas but to have gone the whole way in recognizing the right of the government to regulate production. Mr. Filburn, an Ohio farmer, had planted 23 acres of wheat with an acreage allotment of 11.1 acres. He fed the excess marketing surplus of 239 bushels, preferring not to take advantage of the loan provisions. The court ruled that he was subject to the penalty of \$.49 a bushel or \$117.11. The opinion was unanimous.

In this opinion the court concluded with the following declaration of policy which may have wide application:

"That the appellee is the worse off for the aggregate of this legislation does not appear; it only appears that, if he could get all that the government gives and do nothing that the government asks, he would be better off than the law allows. To deny him this is not to deny him due process of law."¹⁸ Professor Sears in his recent review of Supreme Court Opinions¹⁹ noted that this opinion seemed very important, "perhaps the most important opinion under the commerce clause since Chief Justice Marshall delivered his memorable opinion in *Gibbons vs Ogburn*"²⁰ in 1824.

I do not present these remarks on the court decisions as anything more than suggestive comments. But surely the decisions are not to be taken lightly. And it is no real criticism of the cases to observe that the court may again change its collective mind on these questions as the times and the composition of the court change. In our system of political economy it is left to the supreme court to rationalize such changes in the rules as may be necessary to permit the orderly transformation of our society. This is the great safety valve in our economic system, and is ultimately the means of orderly rather than violent revolution.

III

If one were to deal at all adequately with the significance to farm people of prospective institutional changes, he would have to con-

sider many more aspects of collective action. In the broad view it is clear that we are engaged in the tremendous task of changing the working rules of economic organization in an effort to cope with the problems of a new era. Since the first World War, we have made a strenuous effort to reduce the instability and insecurity in American agriculture and in the economy generally. The problems for agriculture have been complicated by the ominous fact that farmers are little folks in an age of great combinations. However, as I read the record, I have no doubt either that we can or will in the proximate future avoid depressions of the magnitude of those of the '20's and '30's. The relatively bright outlook for agriculture is darkened only by the contingency of war on a grand scale. Barring this catastrophe the major task of economic policy is that of changing the working rules to twentieth century specifications.

CURRENT INSTITUTIONAL TRENDS IN BUSINESS

A. C. HOFFMAN

Kraft Foods Company

I SHALL begin this paper with a definition and a premise. The definition has to do with the word "institutional." By institutional trends in business, I shall mean (1) changes in the size and scale of the enterprise unit, (2) changes in ownership form (i.e. individual, corporate, cooperative or public) and, (3) in the method by which economic equilibrium is achieved.

My premise is that economic institutions are the result of, and are shaped by, the technology of the times. Since commerce and industry began, commercial organization has gone through several cycles of change. Economic historians tell us, for instance, that the framework of modern big business has been sketched several times during the past 2,000 years. The small, specialized business unit has dominated the trade of one era, the large and far-flung enterprise has dominated the trade of another. And back of these changes in business organization have been changes in the techniques of production, communication, transportation and distribution as they were developed in each of these eras.

I am aware that there are many who contend that economic institutions can and should be *consciously* shaped according to some set of eternal verities or moral values which men try to define in terms of good and bad. I am not of this school. Basically, though to some extent an over-simplification, I think it is true that the economic history and progress of mankind is to be explained in terms of economic determinism. If we must think of economic institutions in terms of good and bad, and these are very intangible concepts, my view is that those institutions and forms of economic organization are best which are most likely to develop and utilize modern techniques of producing and distributing economic goods and services.

The most important economic development of the past 50 years is the tendency toward greater size and scale in all parts and phases of the economy. This is true in business, in labor, and to a lesser extent, in agriculture. Without such an increase in enterprise scale, modern techniques of mass production and mass distribution could not possibly have been applied. Yet there continues in many quarters a prejudice against economic size per se—whether exemplified in big business, big labor, or big agriculture. This unreasoned preju-

dice is traceable in large part, I think, to a failure to understand the nature of economic institutions and why they never can or should resemble those which prevailed 200 years ago.

It is important first that we make clear the universal nature of this trend toward scale. In industry, it has mainly taken the form of corporate growth; in labor it is exemplified by the federation of individual workers into unions capable of wielding economic power on an industry-wide basis; and in agriculture, both by an increase in the size of the family farm, and by the agricultural cooperative movement. It is important also to realize that in business organization, this increase in scale has taken place at *all* size levels. Enterprises of scale are not confined to the so-called national companies, although this is what people commonly have in mind when they refer to big business. Probably even more important is the less publicized increase in the average size of what we ordinarily refer to as "small" business. For the truth is that much so-called small business is not small at all, if by that that term we have in mind an enterprise the capital for which can ordinarily be supplied by one or a few men. Certainly a locally-owned manufacturing establishment worth a million dollars and employing upwards of a hundred people can hardly be called a family-sized unit. But except for the fields of agriculture, retail distribution and the services, how much of our economy is today comprised of units smaller than that?

What is back of this trend toward larger business units? The answer to increasing scale throughout our economy is to be found in modern technology, which has broken apart the business forms and institutions of a by-gone era and forged new ones to give itself expression.

One could go on all day listing examples of how technological innovation has been related to subsequent changes in business forms, and I shall confine myself here to only a few examples from the food industries. The meat packing industry as we know it today owes its origin to the introduction of the refrigerator car about 1875, which made it possible to concentrate livestock slaughter in the production areas. With slaughter thus concentrated geographically, it was possible to apply mass production methods to the slaughtering process and the reclamation of animal by-products. Likewise, the mill roll and separation of flour by means of air current, plus the application of modern power, took the flour milling industry out of the grist mill era. Vegetable canning, bread baking, cheese processing—the most modern and efficient tech-

niques for doing all these things require single plant expenditures running into the hundreds of thousands and even millions of dollars.

Equally important as a factor in the growth of large-scale enterprise have been the techniques of mass distribution. As a matter of fact, economies of distribution are probably more important than economies of plant production in the evolving of companies from a local to a regional to a national basis. Here again there is a technological basis so obvious that its relevance is seldom noted. For instance, why didn't chain stores and mass distribution evolve 100 years ago? The answer is simply that mass distribution could evolve only with modern techniques of record keeping, of communication and transportation. Imagine if you can, trying to conduct mass retailing without the typewriter, the adding machine, the cash register, and the automobile.

Another factor to be noted is the relevance of technology for the function of business management. Modern means of communication make it possible for the skills of management to be extended over a business enterprise which is national or even international in scope. One of the important factors in the growth of large enterprise is the use of specialized skills in management—special skills in merchandising, production, purchasing, research and all other elements that go to make up business operation. Not even a genius can combine all these special management skills. Here again some of our old economic principles are wrong when we try to apply them today, because classical economics taught that management was a limiting factor to the size of business enterprise, and they wrongly applied to the factor of management the principle of diminishing returns. As a matter of fact, the economic principle of division of labor is as applicable to the function of management as it is to hand labor, and the curious failure of some of the older economists to observe this may have been due to the fact that in those days the prevailing technology did not permit geographical extension of the management function.

By emphasizing technology as a factor for larger size in business enterprise, I have not meant to leave the impression that there is not an important place in the economy for small enterprise. Small enterprise is, and probably will continue to be, the predominant enterprise scale in many lines.

In agriculture, for instance, modern machines for production—the tractor, the combine, the corn picker, the milking machine—can be efficiently used on a family-sized unit. The most efficient

machines it would be possible to design for these types of work probably would require large amounts of land and capital, but this efficiency factor difference has not thus far proved sufficient for large-scale farming to make headway comparable to large-scale enterprise in many lines of industrial manufacturing.

Similarly, there are many parts of industry, particularly in distribution and the services, where technology has not been compelling in its effect on economic institutions. The most important development in food retailing during the past 15 years has not been the growth of regional and national chains as it was during the decade of the 1920's, but rather an improvement in the methods and efficiency of the independent retailer. Self service retailing and the integration of the wholesale and retail function through the cooperative efforts of independent retailers have given them as well as the corporate chains many of the advantages of mass retailing.

In the field of industrial manufacturing, there is of course a mixed picture. In some of the heavy industries—automobiles, steel, airplane construction—modern production methods leave no place for what can properly be called small-scale enterprise. But there are many lines of fabrication and processing where this is not true, and where medium-sized and even small units can compete on the basis of approximately equal productive efficiency.

This is especially true in the field of food processing, which explains why most lines of food processing are a healthy admixture of hundreds and even thousands of firms, ranging in scale from family-sized units to national corporations. One cannot describe in a paragraph the business pattern in the food industries, because each line is different. But generally speaking, you will find in every major line from three to ten concerns operating on a national basis; then a considerably larger number, similar in structure and using similar techniques and distribution, operating on a regional basis; and finally, hundreds of smaller independently-owned units, varying widely in size and type, doing business on a local basis.

From the standpoint of the number of firms involved, and the variety of techniques of production and distribution to be found, the food industries are probably the most competitive of any major sector of the economy. Concentration of control has not proceeded as far as in some other industries, and for technological reasons probably never will. This does not necessarily mean that the food industries are serving the people any better or any worse than other

sectors where the organizational pattern of business is different. All I am saying here is that the number of firms and their pattern as to size and type is more diverse in foods than in most other major lines.

I want to move now to some observations regarding the applicability of economic theory to modern business organization. The main purpose of economic theory should be to enable us to understand, appraise and improve the economy. And I submit that for that purpose, much of our economic theory today is either inadequate or downright misleading.

When the older economists laid out their theory of value, they ordinarily dealt with the matter of price and output under two assumptions as to competition. On the one side, they took what the economist calls perfect competition, i.e. a large number of small firms no one of which has enough volume to influence price, and on the other side they put single-firm monopoly. Then under the assumption that the small firms and the large firms used approximately the same techniques of production and that the supply function would be the same in both cases, it was easy to demonstrate that the output of a commodity would be larger and its price lower under conditions of perfect competition than under conditions of single-firm monopoly. From this false set of cost assumptions, they and some of their modern followers went on to conclude that any departure from the conditions of perfect competition as thus defined was not in the public interest. The final step in such reasoning is to conclude that a reduction in the number of firms, or an increase in concentration of control which is the same thing, is necessarily bad.

The first thing wrong is the wholly unrealistic assumption as to the cost function. Imagine if you can, the cost of making all the parts of an automobile and then putting it together under conditions of perfect competition as an economist defines that term. Put another way, would you rather buy a car off the assembly line in Detroit, or one put together by a garage mechanic from parts made in 10,000 blacksmith shops? This is an extreme example, but it illustrates how utterly ridiculous it is to draw a line on a piece of paper representing a hypothetical supply function, and then another line to represent the demand function with rectangles and squares and triangles—and from this to draw the most solemn conclusions as to price and output under conditions of perfect competition versus duopoly or oligopoly.

Under the heading of oligopoly theory, some of the later theorists have attempted to give us a set of tools more adequate to the understanding of price making in a modern economy. They say that under oligopoly, the solution depends on how any one of the firms involved may react to the action of its competitors, and since this is neither knowable or predictable, it follows that the outcome as to price and output is indeterminate. Another way to say this is that oligopoly may lead to conspiracy to fix prices, to wholesome competition, or to cut-throat competition, and on the basis of economic theory no one can tell which or where or when one or the other of these situations is most likely to prevail. And when the problem is further complicated, as in reality it is, by taking the cost function into account, who can say on the basis of economic theory at what point concentration of control is inimical to the public interest?

I stated at the outset that the most important institutional change in business is the trend toward greater scale. The second most important change, as I see it, is a greater rigidity in the structure of costs and prices. In my opinion, price levels will never again be as flexible as they were 30 or even 20 years ago, and I don't think any of us really want them to be, although there are some dangers in the direction we are drifting.

Many people associate price inflexibility with the growth of large scale business enterprise. But this has not been the major factor, nor even a very important one. The chief reason for price inflexibility is cost inflexibility resulting from the power of organized labor to influence and control hourly wage rates. In saying this, I am not passing judgment on the matter, but simply pointing out that business today no longer exercises the control it once did over its major cost factor, wages.

One can scarcely pick up a newspaper these days without finding a pronouncement to the effect that prices to consumers have not fallen as much as they should have, and that business is somehow to blame. Currently the food industries are the most common targets for charges of this kind because the spread between the farm and retail price of food has held steady as farm prices have started to decline.

Usually in these charges there is the implication that business profits are too high. In the food field, the net profits of processors are averaging from two to three percent per dollar of sales; and for food distributors, between one and two percent. You can argue that this level of profits is too high or too low; but you can't argue

that a reduction, or even the abolishment of profits in the food field would lead to any significant reduction in food prices. This is so obvious that it hardly merits mention before a group of this kind, but for the amount of newspaper space recently taken up with pronouncements to the contrary.

If food prices or the prices of goods and services generally are to be significantly reduced in the short run, it can come about only through a reduction in the price of raw materials or of wage costs. It has become the policy of government, probably not soon to be abandoned, to put floors under the prices of many of our raw materials, especially those grown on farms. Again I am not passing judgment, but only pointing out another major cause of price rigidity in our economy.

These two developments—more rigid wage rates and raw material prices externally controlled—have great significance for business management. They mean first that the business concern has lost in considerable measure the control of its cost elements. Business is, therefore, considerably more vulnerable to changing economic conditions than ever before. Industrial profits today are being made under conditions of approximate maximum output, with a high break-even point and with relatively inflexible costs. This is not necessarily a prediction of disaster, but it is important that government and labor and agriculture as well as business realize that when a piece of metal is too rigid to bend, it must sometimes break. I am aware that there is a broad and growing school of thought among economists and leaders in all industrial fields who believe intelligently and sincerely that with proper economic statesmanship we can maintain conditions of full employment under a comparatively rigid price and wage structure. I am partly of this belief myself, but with the qualification that we are on new and somewhat dangerous ground in this matter of economic adjustment.

This much is certain: *We cannot have a falling or a rising price structure without a falling or a rising cost structure.* And I further believe we cannot forever guarantee and maintain a fixed level of prices by means of government expenditure and deficit financing without some day going bankrupt in the process. In times past and under a different set of economic institutions, the necessary adjustment of price levels to effective demand, and of costs to price levels, was made by the blind exercise of economic forces—but made nevertheless. Today economic adjustment is in considerable part

the outcome of bargaining and negotiation between corporations and labor unions and cooperatives, with the government itself increasingly a participant. Under these circumstances, economic adjustment is no longer automatic, but in large part administered or negotiated or legislated. This is inevitable and I think our economy can cope with it. But economic power in the hands of whatever group, including the government itself, can be a dangerous thing unless directed wisely and, to a greater extent than heretofore, unselfishly. I believe our economy will stand or fall on this issue, and I am one of those who think it will stand.

What does all this mean for the individual—in terms of his material well-being, his economic security, the satisfaction of his ambitions?

The main purpose of an economy of whatever kind—be it one of small business, large business, free enterprise or socialism—is to turn out the largest possible supply of goods at the least cost in terms of human effort, and then to distribute these goods in accordance with the contribution of those who have helped to produce them. The first test for any set of economic institutions is the extent to which they serve the material needs of the people. And the first requisite for this is that our economic institutions permit the development of and give expression to those techniques of production and distribution which are most efficient in a physical sense. Measured by this standard, the performance of American business enterprise is unmatched.

On the second count—economic security for the individual—there is considerable room for improvement. The quicker all of us come to admit this and get down to doing something about it in commonsense terms, the more secure our free enterprise system will be. Business itself can do a great deal—and much has already been done—to regularize and plan production schedules so that employment is as regular and steady as management can make it. But this in itself is not enough, because management cannot guarantee employment in the face of financial loss.

Those who oppose additional social security, with funds contributed jointly by employees, employers and government are a small and diminishing band. But in this altogether laudable objective of great economic security for the individual, let's not overlook two things. The first is that social security, like other good things, represents a cost to society; and we must pay for it in part by deductions from our wages, in part by having its costs added to the prices

of the goods we buy, and in part by additional taxes. Social security is not something that can be squeezed out of business profits in some magic fashion. Moreover, we must be on guard against justifying indolence in the name of social security.

Finally, our economic institutions must give incentive to the individual and the enterprise group. This is the essence of the free enterprise system and the thing which chiefly distinguishes it from the various forms of socialism.

One of the criticisms commonly made against corporate enterprise versus small individual enterprise is that it stifles the individual. It is one of our traditions that the goal of achievement in business is to own and control an enterprise of one's own, and when young men seek the advice of their elders they are in most cases still solemnly advised to go into business for themselves. It is time we looked at this, too, in more realistic fashion. For the truth is that only a very small percentage of people can ever be individual enterprisers in this sense because ours is no longer predominantly an economy of small business.

Some of you may have seen the results of a recent poll of college graduates conducted by *Fortune Magazine* in which a majority indicated their preference for work with large corporations, or with the government or in the field of education, in preference to going into business for themselves. The poll-taker was somewhat worried that the spirit of enterprise was going out of young men, though I think his fears were groundless. The important thing about this poll and the point I want to make in connection with it is that an increasing number of people think they can find satisfaction for their ambitions by working within groups and organizations rather than as individuals.

What I have tried to demonstrate in this paper is the relationship between men, machines, and economic institutions. It may seem an oversimplification, but I think basically the relationship is a causal one. Through their ingenuity and resourcefulness, men have developed a technology requiring greater scale of enterprise. Economic institutions adequate and proper to the simpler technology of an earlier age have had to give way to modern business and industrial forms of organization. Changing institutions have in turn had their effect on men, their ideals, their values and their relationships to each other. In short, under our private enterprise system we are moving from economic individualism in the old sense to economic groupism.

LABOR'S AIMS AND WHAT THEY MEAN TO AGRICULTURE

DONALD MONTGOMERY

UAW-CIO

YOU ask me to discuss developments in organized labor that affect the outlook for agriculture.

I shall conclude: 1, that agriculture need not expect organized labor to accept a reduction in wage rates; 2, that agriculture need not fear that organized labor will join forces with those who hope to drive farm prices down; 3, that agriculture should welcome and share in organized labor's primary objective, which is the maintenance of continuous and expanding full production and full employment year after year.

These conclusions are based upon a review and interpretation of labor's progress toward increased purchasing power over the last 35 years. After reviewing that progress, I shall try to interpret for you labor's experience in these years and the new objectives that have grown out of this experience. Then we can see what it means to agriculture.

I

The record of labor's progress toward increased purchasing power since 1914 shows:

1. Until 1944 there was an almost unbroken yearly increase in the hourly wage. In only seven years did the money wage fail to increase, and in only four (not the same) years did the real wage fail to gain.

2. Labor has won more through increased wages than through falling prices. In 23 of these years prices were rising, and in those years the increase of the real hourly wage averaged nearly four index points a year. In 11 years of falling prices, the real wage increase averaged less than two index points. In short, labor did better in good times than in bad times. It has not been proved to labor that it can make progress by accepting a stable wage rate while waiting for industry or agriculture to reduce prices.

3. Buying power of the hourly wage held up well during the depression, but this did not prevent a disastrous fall in the buying power of total wage income. This was the beginning of an experi-

ence which has had great significance in shaping labor's present objectives.

4. Labor won a striking increase in its hourly wage rate in 1934. This reflected the declared policy of the government in favor of higher wages and in support of labor unions. Such official support was an important new experience for labor.

5. Another major increase in the hourly wage took place in 1937. This followed the first large development of industrial unions and the invasion of the basic open-shop industries by organized labor. Union membership had dropped from five million in 1920 to less than three million in 1933, but in 1937 it suddenly increased to seven million. Organization continued after 1937 and the hourly wage continued to rise.

6. From 1939 to 1944 the rise in the hourly wage was quite overshadowed by the great increase in buying power of total wages. Here was concrete experience with full production and full employment. Here was proof of what full employment could mean.

7. After 1944 came the first significant decline in the real hourly wage during all this period. The 36 cent rise in money wage since 1944 was wiped out by price increases. The reduction in hours and employment resulted in a 30 percent reduction in the buying power of total wages. This is another important chapter in labor experience creating a primary interest in full employment.

8. While the money wage and the real wage both made gains between 1948 and June 1949, the buying power of wage income fell because plants were shutting down and workers were being laid off. This rounds out the experience which began with the depression 20 years ago.

II

Now let us clothe this statistical skeleton with living issues. What new purposes has labor discovered out of this experience?

1. There is, first, the proof that organization pays. Compare, for example, labor's gains during the alleged prosperity of the '20's with the gains it made during the limited recovery of the '30's. In the earlier period union membership fell from five to three million. It rose from less than three million in 1933 to nine million in 1939. Increase of the hourly wage in the later period was $3\frac{1}{2}$ times its increase in the earlier years. Buying power of the total wage increased 50 percent during the '20's; 100 percent from 1932 to 1939.

Success of industrial unionism in basic mass production industries was the key to this striking success in the 1930's. The strongholds of monopoly power and the open shop had been breached. Labor had effectively challenged the anti-labor low-wage policies of these basic industries.

2. The war and postwar years brought labor new experience and new interest with respect to prices. Both wages and prices were under government control during the war. These controls were tied together. Labor had to concern itself with both, and gained a lively awareness of the difference between money wages and real wages. Out of this experience labor's postwar wage demands called for increased real wages to be paid out of profits without an increase in prices. This labor objective was based on the belief that distribution of the proceeds of full production must provide purchasing power sufficient to support full production. But industry rejected this proposal. After dealing price control its death blow in the early months of 1946, key industries took the lead in agreeing to wage increases which, round by round, they used as an excuse to increase their prices and to add to their profits.

Many people were convinced by this experience that industry was right when it said wages could not be raised without raising prices, the proof, to them, being that industry *did* raise prices whenever it raised wages. But organized labor was and is convinced of the soundness of its wage-price-profit proposals. For it has seen the tremendous profits which industry made as its price increases cancelled out wage increases. It has seen the resulting decline in buying power of wage income. It has heard industrial leaders say that they must accumulate profits in boom years in order to provide dividends for the bust years which will follow.

3. This experience gives rise to labor's primary new objective—that affirmative measures can and must be taken to eradicate booms and busts and to maintain production and employment at rising capacity levels year after year. The lesson was learned in three stages.

The depression which began twenty years ago convinced most people that something must be done to prevent the waste of human labor and the human misery of such catastrophes. That was lesson one. Lesson two was the experience of full employment during the war—if we have it for war, we can have it for peace. The postwar decline in labor's buying power, followed by the closing of plants

and the laying off of workers, provided lesson three—that something more than the voluntary performance of private enterprise is necessary to prevent booms and busts and to make full production and full employment a continuing reality.

Labor knows that booms and busts are not gifts of nature, but man-made. It believes that what is man-made can be man-controlled. In place of the controls imposed on the economy by leaders of big business, it calls for controls in which all economic groups may participate. For the *private* planning by monopoly industries, it would substitute responsible *public* planning. It urges that government fiscal policies be designed to stimulate levels of consumer buying power and investment adequate to support full production and to promote its expansion.

Private enterprise also welcomes government aid, indeed demands it. Labor's program differs only because it wants government as a full partner in the process. It is business, not labor, that has been inviting the government into private enterprise all these years, but always on a heads-we-win-tails-you-lose basis, beginning with Hoover's Federal Farm Board and Hoover's Reconstruction Finance Corporation 20 years ago. Labor's plan is radical only in that it would have government promote successful enterprise, not merely mop up the failures.

These full employment objectives of labor are spelled out, though imperfectly, in the proposed Economic Expansion Act of 1949, recently introduced in Congress. It proclaims purposes which we endorse, but tends to leave government as the silent, rather than the active, partner to private enterprise, assigning to it the menial task of subsidizing the imperfections of business instead of the bold task of promoting positive performance on behalf of the general good. I think labor will back this measure if it can be changed to provide a creative purpose, rather than a crutch, for the American economy.

4. Pursuit of our full employment objective involves another—political action. Labor is in politics for keeps. It is in politics to cope with a basic issue of our times—the issue of the private power of monopoly vs. the public power of the people. This is the question that arises out of labor's postwar experience with wages, prices, profits, employment and production. Shall we have private government of the economy or public government?

To come to grips with this issue we must concern ourselves about the exercise of public power. We do not intend that government autocrats shall substitute themselves for economic autocrats. We must get into the governing process. That is, we must get into politics. We? Not only labor, but all of the American people who live by their labor rather than by their property.

III

What does all this mean to agriculture? Back in the 'twenties labor's drive centered largely on a higher wage per hour, and for only a select few within the ranks of labor. That being so, the farmer's problem was remote. Cheap prices for food were desirable, no matter what they might mean to food producers.

This certainly is not labor's view today. Labor sees that the purpose of farm price supports is similar to its own purposes in collective bargaining. The farm program began during the depression at the same time as the organizing drive which brought labor unions their great increase in membership. And the purpose was the same—to provide human security against the onslaught of economic forces. And the opposition comes from the same quarter. The attack upon farm price supports, the demand that farm prices be left to unfettered supply and demand, the proposal that each farmer should decide in isolation how much acreage to till or livestock to feed, have come from the same financial and industrial sources that still hope to divide labor, to destroy its collective bargaining power and to drive it back to competitive wages.

Labor endorses farm price supports. It wants food as cheap as it can buy it, but not at the expense of sweatshop farming. This is not based on sentiment but on a recognition of common interest. Organized labor has little reason to be grateful to organized farmers. It has experienced a hostility from that quarter which could force a fatal rift between them were it not for the fact that so many organized workers were born on farms and so many more have family ties reaching back to those who work the land. They know farming is hard work and hazardous. And they have seen the farmer's principal crop, his sons and daughters, come to the factories to work and fight side by side with other workers to protect their rights as human beings against the inhumanities of the factory system.

But labor's most important support for the farm price support program is its determination to achieve steady full employment and production at good wages. For only full employment can assure good markets, and price supports are in peril if markets collapse. The security which the farm family wins through price supports is as vulnerable as the security which the worker's family wins through collective bargaining. A return of depression can destroy both. Even a continuation of the present "corrective adjustment" (as the business journals call it) with the labor market stabilized at some five or six million unemployed—threatens the programs of farmers and city workers. Curtailed production and employment is welcomed by big business precisely because it holds out the hope of cheaper labor and cheaper raw materials.

Success on the part of labor in achieving its goal of steady and expanding full employment means a great deal to agriculture. It means high and steady farm income. It means a genuine opportunity to practice the conservation which the nation needs. It means an abundance of the goods that relieve toil. It means better farm homes, good rural schools, and hospitals and clinics that are accessible to farm families. It provides the only sensible hope in sight that we shall ever begin to do something for that suppressed one-fourth to one-third of families on farms who are truly the forgotten families of our day.

Labor's full-employment goal means the same things for all of us. It promises the only possible solution for the restrictive and separationist policies which plague all our groups. For if we go back to chronic unemployment we shall go back to prohibitive tariffs. And if we do not import, we shall not export. So again we will seek salvation through scarcity. Labor will join up with employers to restrict output, and agriculture once again, as in the '30's, will try to get ahead by attempting to make farmers imitate monopoly, and with as little success.

But labor will not achieve its goal unless farmers share in the winning of it. Nor will the two together make headway unless they and other groups of people get into politics. For the issue facing labor and agriculture is not merely what the welfare of the one means to the welfare of the other. The issue, I repeat, is whether the American people will create a grass-roots political democracy through which they can participate and plan together, can estab-

lish the goals which they desire to achieve, and can carry out through their governments such public policies as they find necessary. If they default, they leave the outcome to government by private monopoly or to a bureaucracy manipulated by the powerful few, and there will be little to choose between the two.

Are these conclusions too bold? In these days of corroding hysteria and of professional withdrawal, the attempt I have made to extract meanings from history and to create goals out of experience may strike you as neither safe nor persuasive. Well, in that event I ask you, who has, if labor does not, a program to make meaningful the future of our people?

MARKETING RESEARCH UNDER THE RESEARCH AND MARKETING ACT

BERNARD JOY

Agricultural Research Administration

WHILE conception took place with the passage and signing of the Research and Marketing Act on August 14, 1946, birth of the program did not occur until almost a year later, July 30, 1947, when funds to carry out the Act were made available. Although some plans for the baby were developed during the period of pregnancy, the record of progress began just two years ago.

Just as a parent can record the progress in height and weight of a two-year old child, so we can record the growth in the appropriation from the original \$9,000,000 to the present \$19,000,000.

On the other hand, just as it is difficult for a psychologist to appraise the mental and social growth and potentialities of a two-year old, so likewise is it difficult to appraise the social and economic significance of a program so young.

Those of us on the staff that has provided nursing services for the youngster are naturally proud of his progress. Our appraisal may not be as objective as it should be, because our relationship with the child involves the love that is a natural outcome of intimate association. In inviting me to speak on this topic you have exposed yourselves to the same danger as when you encourage a parent to talk about his child.

Those of us involved in the administration of the program are proud of its development. We believe that the person chiefly responsible was exceptionally well qualified for his task. E. A. Meyer had a clear vision of the potentialities of the program and a skilful hand in getting hundreds of people to assist in its development. His ability to obtain and amalgamate the constructive thinking of leaders among producers, processors, and handlers of agricultural products is a significant administrative achievement. The development of a program involving coordinated effort of personnel in several federal agencies, in the Land Grant Colleges and State Departments of Agriculture, and in private industry is not only an achievement of which each participant can be proud, but an administrative accomplishment that establishes Woody Meyer as a leader who deserves our highest tribute.

We likewise believe that we are most fortunate to have P. V. Cardon, the able and experienced Agricultural Research Administrator, as the person who will carry forward as leader of the developing program.

The situation on August 1, 1947, was not a simple one. The Act left a great deal of latitude with regard to (1) what was to be done, (2) who should do it, and (3) how it should be done.

What should be done?

Title I, Section 9 of the Act provided for allotment of at least 72 percent of the funds appropriated to the State Experiment Stations on a formula basis. It provided that up to 25 percent be allotted to the States for cooperative regional research. Except for the provision that at least 20 percent of such funds should be used for "marketing research projects" discretion regarding the use of these funds is limited only by the broad language "research into the laws and principles underlying the basic problems of agriculture in its broadest aspects."

Sections 10(a) and 10(b) provide for research in utilization and research in cooperation with the states in fields other than utilization. In other words, almost any type of research—new uses of farm products, nutrition, prevention of waste, animal and plant breeding, housing, soil and water conservation—all could qualify, and the list could be much longer.

Title II provides for research, educational, and service work in marketing. Marketing is a broad field encompassing preparation of the product on the farm, grading, packaging, processing, freezing, storage, transportation, wholesaling, retailing, consumer preferences, foreign trade, costs and margins, and pricing practices. This list, too, could be lengthened greatly.

Who should do it?

The Act provides for utilization of Federal agencies, State Experiment Stations, State Extension Services, State Departments of Agriculture and Bureaus of Markets, and private organizations. It specifies state matching of funds for certain work and permits contracts with public or private organizations when they can carry out work "more effectively, more rapidly, or at less cost than if performed by the Department of Agriculture."

How should it be done?

Developing organization, policies, procedures and staff is not simple when it involves agreements with a variety of Federal agencies, cooperative relationships with several agencies in each of 48 states, and contractual agreements with private agencies.

The Research and Marketing Act has at times been considered to be a Marketing Research Act. This is unfortunate, as legal provisions require that only about five percent of the funds be spent on marketing research projects, if utilization research is not classified as marketing research. Under Title I, Section 9, 80 percent can be spent on other fields. Title I, Section 10(a) funds are to be spent on utilization research, and Title I, Section 10(b) funds on research other than utilization. Title II funds could be spent wholly on marketing services and educational work. Of course, that was not the intent of the Congress, and a large part has been spent on marketing research.

The desirable flexibility in the Act did pose the administrative problem of deciding how much of the total funds appropriated should be spent on marketing research? How much on research in other than marketing? How much on service and educational work in marketing? The decision on these broad questions was not reached by one person or at one time. Fifty-one experiment station directors acting individually have had major responsibility for making the decision in regard to \$3,600,000 of the appropriation for the fiscal year 1950. A committee of nine experiment station directors had major responsibility for making this decision in regard to \$1,250,000. The results of their selection of projects is that approximately \$2,000,000 of Title I, Section 9 funds will be spent on marketing research projects in 1950 and this will be supplemented by about \$1,500,000 of state matching funds.

Some people classify all research in utilization of farm products as marketing research. Obviously development of new or improved uses does increase market outlets. However, almost all of this research is technological rather than economic. As it is covered by a separate section, 10(a), in the Research and Marketing Act, the amount is annually fixed by Congress. For the fiscal year 1950 it is \$5,000,000.

Title I, Section 10(b) is for cooperative research with State Experiment Stations in fields other than utilization. These funds can be used for marketing research and most of the Federal cooperation in conducting regional marketing research projects under

Section 9b3, has been financed from 10(b) funds. The amount in fiscal year 1950 for such cooperation is approximately \$350,000. As I expect the speakers that follow me to discuss the regional marketing research program, I will confine the remainder of my discussion to the marketing section of the Act known as Title II.

The appropriation for Title II for the fiscal year 1948 was \$2,000,000 instead of the \$2,500,000 authorized for the first year. In 1949 it was \$4,750,000 or 95 percent of the second year authorization. However, \$6,000,000 for 1950 for Title II is 120 percent of the second year authorization.

Title II funds are to be spent for marketing work. This can be either research or service and educational work. One of the difficult administrative decisions has been how to divide the funds between the three fields. It is complicated by the fact that insofar as possible the service and educational work in marketing is to be carried out through state agencies that must match Federal funds on a 50-50 basis.

The actual decision regarding the amount of funds going to State Departments of Agriculture and Bureaus of Markets for service work and to State Extension Services for educational work has been made largely in the states. To qualify for matching the state monies must be in addition to those available for marketing work when the Act was passed. The amounts of such new money that the States have had for marketing work has largely determined the amount of Title II funds used for educational and service work in the States. The Agricultural Research Policy Committee recommended that funds made available by the States be matched if their work proposals were sound and provided the amounts to individual states was not disproportionate to the total. With minor exceptions the amounts of money the states have had available have been matched and the portion of Title II funds going to them has approximated 20 percent of the total appropriation for Title II. In the fiscal year 1950 approximately \$1,200,000 of Title II funds and an equal amount of state matching funds will be expended on new service and educational work in the states.

Not all the remaining Title II funds are expended on marketing research as contrasted with marketing service work. Federal agencies may do service work and contracts may be executed with public or private agencies for service work. However, decisions in regard to such additional service work have been made on a project by project basis weighing the value of proposed service projects against

the value of proposed research projects. Some projects are difficult to classify as research or service, but based on a somewhat arbitrary classification the 1950 expenditure on Federal agency and contract projects for marketing service work will be approximately \$950,000.

The basic unit for consideration of what work should be done in the field of marketing research, how it should be done and by whom it should be done has been the work project. In 1950 there will be 95 marketing research work projects supported by Title II funds. The expenditure for them will be approximately \$3,850,000. The total Research and Marketing Act funds spent on marketing will be about \$6,200,000. With about \$1,800,000 of new state funds the total program is about \$8,000,000 greater in 1949-50 than in 1946-47.

Administration is sometimes divided into six major functions:

- (1) Developing policies
- (2) Developing plans of work and authorizing expenditures of funds to carry them out
- (3) Development of an organization and assignment of responsibilities
- (4) Selection, training, supervision, and control of personnel
- (5) Coordination of effort
- (6) Reporting accomplishment

A large portion of the administrative functions related to marketing research on Research and Marketing Act funds have been decentralized. Only functions 1, 2 and 5 have been the responsibility of the Administrator and his staff. They have worked on policy, plans of work, coordination, and budget justification.

The plans of work have all provided for the actual conduct of the research by agencies of the Department, State Experiment Stations and private research organizations. The administrator of the agency conducting the research has been responsible for the development of an organization, personnel and reporting the results of research work.

Two of the most important items of policy were indicated by the Congress in the Act itself. They are: (1) Use of facilities of existing agencies and organizations for the conduct of the work, and (2) Use of committees representing producers, industry, government and science to make recommendations relative to work to be done, and to assist in obtaining necessary cooperation to carry it out.

Plans of work have been developed within this framework. During the past two years final decision on what work is done and

what work is postponed has been made by the Administrator in conference with eight assistants. Before this group is a long list of work projects each with a price tag on it. The project titles are supported by a research outline which tells:

1. The problem and need for the work
2. The objective to be reached
3. How the work would be done
4. Who will do the work

Also before this group is the amount of money that is or may be available. This figure has always been far below the total of the price tags on the individual proposals. The problem is to reduce the list either by eliminating items or cutting the price tags until the total equals the money available.

When the group assembles it has some criteria in mind that are applied to each proposal. As these criteria have not been formally stated, I will express them in my own words.

1. Does the work qualify under the provisions of the Act?
2. Is the work part of a broad field that should receive emphasis?
3. How important is the problem to be solved in the minds of producers, industry and scientists as indicated by the priority given to it by advisory committees?
4. What is the probability of the proposed research being conducted successfully in light of the personnel and facilities available? Is the group proposing the work the one best qualified to do the job?
5. How does the particular research proposed fit together with work already completed or under way and with other work proposed?
6. Considering the first five criteria, how high is the cost in terms of probable results?

Many months of work have preceded the conference session at which some work projects are selected and others rejected. This work has consisted of delineation of the criteria and study of the individual work proposals.

The individual proposal has been checked against the provisions of the Act and the administrative policies set up pursuant to its provisions. Frankly one of the most perplexing questions is "What is marketing?" Text book definitions are of little help when you are faced with a proposal to reduce loss of a processed product during storage and develop methods for preventing the loss when the presumption that loss is caused by an organism that infected, but could not be detected in the raw product before it was harvested, is just as likely as the presumption that the loss is caused by conditions to which the product was exposed in processing, transportation or storage.

Determination of the broad fields that should receive emphasis is one of the major contributions of the 11-man Agricultural Research Policy Committee set up by Congress in Title III of the Act. This Committee meets quarterly. They point out the need for consideration of broad policies such as a desirable balance between livestock numbers and human population. Congressional hearings are also rich in indications of broad fields needing emphasis such as recurring questions on why the price spread between the farmer and the consumer is so great.

Establishment of the relative importance of various problems in particular fields has been the chief purpose of the meetings of 22 commodity and functional advisory committees. Before the committees meet a representative group of department scientists meet and develop a list of problems for the committee to consider. The advisory committee reviews the progress of work under way, adds problems to the list and arranges the list according to relative importance of problems.

The advisory committee recommendations are a major consideration in the selection of problems on which the agencies develop research proposals. However, the priorities suggested by the research agencies when they submit proposals may vary from those of the committees in light of the availability of personnel, facilities and "know how." Work basic to the solution of some problems may be barely started while the solution of other problems may involve the application of well-established techniques to an additional commodity or function. The plan of work and allocation of funds that has resulted from this process is summarized in the following table showing the budget for Title II funds under five major and 22 minor classifications

TITLE II. MARKETING RESEARCH AND SERVICES

	1948 Allotment	1949 Allotment	1950 Budgeted
<i>I. Basic data and information</i>			
a. Reports on supplies, prices and movement of farm products.	\$ 162,750	\$ 229,700	\$ 238,000
b. Improving market news and other market information services.	63,560	150,800	173,000
c. Promoting greater use of market information through State educational and service agencies.	16,000	156,000	175,000
Total, Financial Project I	\$ 242,310	\$ 536,500	\$ 586,000

TITLE II. MARKETING RESEARCH AND SERVICES (Continued)

	1948 Allotment	1949 Allotment	1950 Budgeted
II. <i>Expansion of outlets for farm products</i>			
a. Development of foreign outlets.	\$ 63,800	\$ 161,000	\$ 200,000
b. Exploring opportunities for expanding domestic markets.	38,840	158,700	193,000
c. Determining consumer preferences.	95,200	167,400	206,000
d. Consumer education.	43,000	86,000	125,000
e. State service programs to expand market outlets.	265,000	374,200	425,000
f. Analyses of supply, demand, and consumption.	69,850	139,100	149,000
Total, Financial Project II	\$ 575,190	\$1,086,400	\$1,298,000
III. <i>Marketing services, costs and margins</i>			
a. Analyses of marketing services.	\$ 24,200	\$ 70,900	\$ 149,000
b. Studies of pricing practices	21,000	41,300	43,000
c. Measurement of costs and margins.	41,000	318,800	549,000
Total, Financial Project III	\$ 86,200	\$ 431,000	\$ 741,000
IV. <i>Improvement in preparation and handling of farm products</i>			
a. Development and improvement of grades and standards.	\$ 174,200	\$ 496,300	\$ 483,000
b. Developing improved containers and methods of packaging.	50,200	125,000	140,000
c. Improving transportation services and equipment	14,250	51,700	120,000
d. Economic studies of new and improved processing methods.	58,650	140,000	255,000
e. Improved storage and conditioning of farm products	95,900	322,800	422,000
f. Quality preservation in marketing channels.	64,500	271,600	255,000
Total, Financial Project IV	\$ 457,700	\$1,407,400	\$1,675,000
V. <i>Evaluation and improvement of marketing system</i>			
a. Improvement in physical plant.	\$ 160,800	\$ 252,600	\$ 263,000
b. Increasing efficiency of merchandising agricultural products.	106,800	246,200	315,000
c. Evaluation of market organization.	132,000	211,100	304,000
d. Improving marketing methods and efficiency through State educational and service programs.	166,000	443,000	675,000
Total, Financial Project V	\$ 565,000	\$1,152,900	\$1,562,000
Over-all Administration	73,000	135,800	138,000
TOTAL, TITLE II	\$2,000,000	\$4,750,000	\$6,000,000

ADMINISTERING MARKET RESEARCH—WESTERN PROBLEMS

D. B. DeLoach

Bureau of Agricultural Economics

VARIOUS comments have been made about the general conditions of western regional market research. Opulence, infancy, malnutrition, family troubles over finances, and cerebrospinal ossification are attributed to the program. Obviously there are certain basic difficulties or your program committee would not have chosen to devote so much time to the subject of "Administering Market Research."

There are basic problems that have developed in the administration and activation of a large-scale regional market research program. They are centered mainly around specific points, namely:

1. The suitability and value of the market research projects regionally and to the state.
2. The inexperience of the existing market research staffs.
3. The feasibility of expanding the market research staff to handle projects of short duration.
4. The allocation of staff time between research and teaching.
5. The manner and extent of state participation in regional research programs.
6. The extent of industry and agriculture cooperation with regional market research agencies.
7. The lack of definiteness regarding the meaning of regional market research.
8. The time required to administer the program.

Suitability and Value

If viewed from the standpoint of research results only, the first two years of western regional research was almost a total loss. On the other hand, the eleven western states did effect a working mechanism through which regional research could be done provided the states develop their research staffs of trained people to carry through their assignments. This latter qualification raises several issues.

The practice of dividing funds among several states to do research on a specific problem implies an obligation to do productive research. This is true even though the funds made available to the station from state and RMA sources are barely enough to meet traveling expenses to the scheduled meetings of the technical com-

mittees. As a matter of good administration, states are going to be forced to ask what economic problems are of regional significance and lend themselves to active participation with several research agencies in the region.

I have had a reasonably close contact with developments in four WM projects. Experience and well defined regional research administrative procedures are lacking. Local pride and the fear of criticism for inattention to local problems make necessary the participation of each state in each of several projects. Frequently no results of consequence are obtained that would not have been obtained through non-participation. The added value of the research to the state is often slight. It is possible that some of this local emphasis will be relieved when regional research publications become better known.

Inexperience of Existing Market Research Staffs

Specific qualifications are necessary if a researcher is to accomplish worth-while results. Competence comes partly from training, partly from experience, and partly from an aptitude for the particular task. Some of the western states are still having a difficult time locating qualified researchers to fill existing vacancies, a condition arising partly from the lack of security of tenure. Others have filled all available positions but have had to choose men insufficiently trained and without any real interest or experience in marketing or markets. Under such conditions the administrator must have sufficient time to plan and to supervise the research program or the entire research operation is characterized by inefficiency and waste. There is reason to believe that most of our western stations have had to face this problem frequently. Inasmuch as experiment station market research administrators have had several new hurdles since 1946, their time must be spread thinly over each of many problems. In one sense, they have been forced until recently to accept the slogan of a prominent farm combine manufacturer, "Once Over and It's All Over."

Feasibility of Expanding the Research Staff

Good management practices in the field of economic research should follow good management practices generally, e.g., the size of labor force should be related to the volume of immediate and potential work. This type of managerial procedure presupposes

the existence of a market research program associated with the needs of industry and agriculture, but it in no sense excludes a core of basic research that might be called "tool building."

Several state agricultural experiment stations have expanded their market research staffs at a phenomenal rate since 1946. Part of this expansion has come as a result of a program begun under state appropriations for market research, but the real stimulus came from funds appropriated for section 9b3 of the RMA. Perhaps it will be shocking to some of you for me to state publicly that several western states and federal agencies (and I know of states in other sections of the country) have been embarrassed with too much money for market research, considering their plans and personnel. There are two reasons for this. The first is lack of time to develop a program and organize a competent research staff to carry through the program. The second comes from inability of research groups to obtain full cooperation from market agencies. Time is helping to correct the first condition because worth-while plans for research projects are emerging for 1950-51, along with better qualified and more seasoned research workers. The second condition is not improving. Marketing agencies are scrutinizing closely requests for confidential records, and are consistently raising the basic question regarding benefits to come from such research. Some business leaders who have been "surveyed" regularly without seeing any results ask frankly whether this is just another state or federal statistics-gathering scheme, the possible use of such statistics being only remotely associated with improving the efficiency of the market processes.

If any significance is to be attached to the foregoing conditions, one might assume that agricultural marketing agencies are much less interested in carrying on the type of regional market research done under RMA since 1947 than is commonly supposed. It is very easy for business people to point out the inconsistency of research designed to improve marketing efficiency while other state and federally supported programs are designed to maintain the status quo. All these factors taken together cause any good administrator to appraise the temporary and permanent personnel needs very carefully. If regional research is continued on the present scale, will the program be modified to require a "floating" group of regional researchers? If the program is not retained, do state civil service and retirement regulations make it inadvisable

to expand the research staffs? Each state must meet these issues in terms of its best judgment as to the basic market research needs of its people and the willingness of the people to finance adequately a worth-while program of market research.

Allocation of Staff Time Between Research and Teaching

There is no denying that western regional market research plans were badly disrupted for two years because the teaching load assigned to many research workers left little time for research. One glaring example is that of the researcher assigned to three research projects in addition to a teaching schedule requiring him to hold classes five days each week. This condition has not been corrected entirely. Conditions within the region are so much better now that harsh criticism for most of the eleven states is unwarranted. It will not be easy for some of the smaller states to completely solve this riddle of minimizing interference of teaching duties with research assignments. The nature of a teaching assignment is such that there is a minimum time requirement involved regardless of the quality of the work. The nature of man is such that there is a maximum time limit on the number of hours he can or will work each day. We have spent ten years in agricultural economics at Oregon State College trying to develop our research and teaching staff to the point where conflicts between the two assignments could be kept to a minimum. The results follow:

Number of staff	Assignment	
	Research	Teaching
	<i>Percent</i>	<i>Percent</i>
4	100	—
1	81	19
3	75	25
2	67	33
4	50	50
1	30	70

The foregoing allocation of time might not look good to other colleges, but it certainly is better than anything we have had previously. Furthermore, we have been able to arrange our teaching program in a manner to permit the teaching assignment to be completed before the research is undertaken. This is a very im-

portant consideration in a small school, because we have a limited number of graduate students to use on a market research program.

State Participation in Regional Market Research

It is difficult to establish any firm rule as to the number of regional market research projects in which a state should participate. The diversification and importance of agricultural activities and the characteristics of the problems should be the determinants. But they cannot be the sole determinants if efficiency is taken into consideration. For example, Oregon has such a wide diversification of crops and marketing problems that a selection based on the urgency of the problem has been the means by which most of our projects were begun. This basis for choosing fields of market research when funds are insufficient to go around may be lacking in many respects, but I cannot see any other practical procedure, all factors considered.

Certain of the eleven western states have established industry advisory committees to work with the stations in developing a market research program. Whether this device will prove satisfactory remains to be seen. The implications are quite clear; in fact, too clear to be entirely comforting to true research workers. It seems that the insistence of commodity groups that their particular problem deserves immediate attention has caused research administrators to divide funds among several projects to a point where no one project is adequately financed or staffed. The foregoing statement might appear inconsistent with my previous remark that research workers are not receiving the complete assistance of agricultural marketing agencies. This is not the case. When a commodity group advises that certain market research would be helpful and it would be interested in having it done with state or federal funds, there is no implication that the members of that industry are obligated to supply the information needed to make the inquiry successful. Some few months ago I sat through a meeting of one of the national commodity advisory groups. The commodity has been subsidized heavily for several years, yet there was very little interest in a study of the economics of marketing the commodity. There was no reluctance, however, to support heartily a proposal to use a substantial amount of research funds for buildings and physical equipment. One could easily raise the question at this point as to whether market research in state and federal agencies

can begin to rely more on good research procedure as a means of maintaining support.

There may be considerable disagreement as to the emphasis each of you will place on the conditions I have mentioned. Regardless of this, your decisions as to the number of research projects carried by your departments will have to be affected greatly by these forces.

Industry and Agriculture Cooperation with Research Agencies

Western regional market research workers have been very successful in obtaining cooperation from marketing agencies where the information needed related to handling practices and market channels. Reasonable success occurs in obtaining selling prices. The success curve starts downward rapidly when questions are asked concerning costs and the components of costs, and the location of market outlets. This type of questioning gets too closely to the only competitive aspect of many businesses. Cost information is also guarded closely by some types of businesses for fear it will be used to their disadvantage in wage negotiations with labor unions. In other instances the kind of cost data sought by researchers is not available and could not be made available without undue expense to the firm answering the questions.

A substantial part of the difficulty of obtaining factual data from marketing agencies stems from the inability of researchers to explain what they want, why they want it, and how such information will be used if it is made available. The inexperience of researchers in a particular field becomes an unusual liability in market research work. Too many researchers are interested solely in assembling a mass of statistics. Market men soon lose patience with a research man who is unable to ask intelligent questions about an industry on which he will later pass expert judgment. This situation has arisen so frequently that one wonders whether the training given students in agricultural economics is alone adequate preparation for market research.

Lack of Definiteness Regarding the Meaning of Regional Market Research

A cursory examination of the eight western regional market research projects leaves one with considerable doubt as to what constitutes regional research. I have tried to be broad-minded on

the subject. On several occasions, however, I have had to defend the actions of my fellow workers in Oregon and neighboring states. The fact that my arguments were accepted left me with the impression that the persons who accepted them were very generous in many instances. Two regional projects can be used to illustrate my point.

I believe the western dairy marketing project is a very good illustration of a regional research undertaking. As nearly as possible the principal states are working on different aspects of the problem of marketing milk. Some of the activities are confined to inquiries into local market problems, but in each instance, these problems are of significance far beyond the immediate area. To an administrator who is unfamiliar with the dairy industry, one has some difficulty explaining the regional aspects of the work in progress. On the other hand, the western group has had no difficulty explaining the regional characteristics of the turkey marketing studies which were brought to a close in June, 1949. The project looked perfect on paper, but in terms of the work done the regional features assume less importance than they should. I wish to add, however, that this very fact was one of the basic reasons for the development of a thoroughly coordinated program in marketing poultry and poultry products in the western region.

Time Required to Administer the Program

Considerable criticism has been directed toward the regional market research program because of the time required to plan and execute the work in cooperation with other states and federal agencies. There appears to be a reasonable justification for this complaint. Approximately 25 percent of the regional market research funds allocated to Oregon in 1948-49 was spent for administration as a result of direct participation in the work of the regional technical committees. If indirect administrative activities were charged against the projects in proportion to the actual time requirements, I do not believe I would be far afield to estimate the cost at approximately 50 percent of the RMA funds made available to Oregon for regional market research. My observation of the administrative activities of the Bureau of Agricultural Economics relating to the use of RMA 10b funds would indicate very heavy expenditures for administrative purposes. The Bureau's problem, like that of the states, arose from an attempt to spread its funds

thinly in all regional market research work. Conditions similar to those I have mentioned exist in a sufficient number of states to warrant a very close study of the basic causes and the possible implications of this situation.

Present Trends

Up to this point I have reported rather gloomily on the regional market research done in 1947 and 1948, recognizing a substantial improvement in the outlook for the current fiscal year. More improvement can be expected for 1950-51. Real progress has been made toward a definitely regional program for milk, poultry, and deciduous fruits. Further progress can be expected on other commodities if these initial steps are approved by the Committee of Nine. But in no case can the western region assume that it has solved its major problems until:

1. It has clarified and simplified the objectives of the regional market research program, and
2. Obtained from the Research and Marketing Administration and the Office of Experiment Stations a consistent, clear-cut, and simple set of administrative procedures that will reduce greatly the administrative confusion connected with the program.

ADMINISTERING MARKET RESEARCH— NORTHERN PROBLEMS

RAYMOND J. PENN
University of Wisconsin

YOU must recognize that my remarks on this subject will be based largely on a few months' experience in one agricultural economics department in one college of agriculture. When Mr. Wells asked me to prepare this paper he indicated an interest in the opinion of one "who has been more or less suddenly forced into the marketing field. . . ." This paper does not necessarily represent the policies of either the Wisconsin Experiment Station or the Agricultural Economics Department.

There is not much question what we are concerned about. It is the Research and Marketing Act of 1946 and the administrative problems growing out of a greatly expanded program of market research. I plan to confine this paper to those parts of the Act which are of most concern to an Agricultural Economics Department in a State Experiment Station.

Research funds may be made available to Experiment Stations under several sections of the Act. Stations may submit marketing projects under Title II, provided new money is available for matching purposes. Some Stations have Title II projects. However, I suspect our experience is rather common. When the Act was first passed our department developed quite a number of marketing research projects to be submitted under Title II. None of the projects were approved until the spring of 1949 when one small research project was activated. New money for matching purposes has been very limited in our Station. However, our 1949 Legislature appropriated some new funds for marketing. To date, then, we have made very limited use of Title II research funds. We may use it more in the future, particularly since a five-man committee of Station directors has been established through which Title II marketing research projects can be channeled.

Another source of research funds available to Experiment Stations is the allotment to U.S.D.A. The U.S.D.A. may contract to have research done by any public or private research agency (Sec. 10a of Title I and Title II). Our department has submitted one proposal of this type which has not as yet been approved. I under-

stand only a few of these contracts have been consummated with Experiment Stations.

My experience with Title II—the strictly marketing portion of the Research and Marketing Act—has been very limited and we have practically no experience with the contract arrangements. Hence, the remainder of my paper will be devoted to that portion of the Act which authorizes appropriations of research funds to the Experiment Stations, namely, Title I, Section 9. This section contains provisions for state research (Sec. 9b1 and 9b2) and regional research (Sec. 9b3).

State Research Under RMA

The funds allocated directly to the Experiment Stations may be used for almost any kind of agricultural research. However, at least 21 percent of these funds must be spent on marketing. The availability of the remaining 79 percent is contingent upon the full expenditure for marketing research. Research supported by 9b1 and 9b2 funds is done under very nearly the same administrative arrangements as have been used by the Stations for many years on all federal grant research. The essential difference is that RMA project proposals must be submitted six months to a year prior to the time when funds will be available for the research. According to a recent announcement from the Office of Experiment Stations all Sec. 9 projects for 1950–51 must be in the Office of Experiment Stations September 1, 1949. The projects will then be submitted to the Bureau of the Budget by September 15, 1949.¹ These proposals will be before Congress when the 1950–51 appropriation is made. It is my understanding that this makes it necessary for the Experiment Stations to use the 1950–51 appropriations only for the projects before Congress at the time of appropriation.

The Agricultural Economics Department at Wisconsin is participating in nine marketing research projects supported, in part, by 9b1 and 9b2 funds. Four of these projects are very similar to and support the regional projects of which I will have more to say later. I said we participated in nine marketing projects because two of them are being conducted in cooperation with our production departments.

¹ *Time Schedule for the Preparation of Cooperative Regional Projects and Budgets*, Office of Experiment Stations, May 5, 1949 (includes schedule for 9b1 and 9b2 projects).

These are some of the problems we face in using 9b1 and 9b2 funds, not necessarily in the order of importance.

1. If we do not utilize at least 21 percent of the 9b1 and 9b2 allotments for marketing the Station will lose funds available for non-marketing research. Obviously, we are under pressure to utilize the marketing funds. If we do not expand the marketing research in the agricultural economics departments we may expect to see an expansion of marketing research in the production departments. Of course, if we do develop a number of new marketing projects we increase our personnel and our space needs which brings criticism from our associates in other departments.

2. The time schedule for submitting RMA research projects does not fit my idea of the way research is done in social sciences. Particularly is this true if the Experiment Station Director cannot shift the funds from one project to another or change the projects. You will recall that the 1950-51 projects are to be in the Office of Experiment Stations, Washington, September 1, 1949. This means the research person must propose the project just about one year before the research begins. I recognize it may have been desirable to demonstrate to Congress the scope of the new research in order to receive the appropriations. The person doing the research, however, is often seriously handicapped if he is expected to work on projects drawn up a year before he starts his research.

A good research program, particularly one that is rapidly expanding, should permit the research person considerable flexibility. The social science researcher should have a plan of work which is in a process of continuous change. He tries an approach which may be fruitless and he should drop it. Or it may open up an entire area that was not before considered significant. For the most part, the usual Experiment Station procedure offers opportunity for flexibility. The director is close to the research staff and he knows the characteristics of most of the research personnel. I am confident many directors approve projects more on their confidence in a researcher's ability to do a good job than on what is said in a project proposal.

It is difficult if not impossible for the research person to prepare a meaningful project statement a year before the research starts. His attempts have resulted in much wasted effort. Most of us have prepared many more project statements for RMA than have been approved. I have had the feeling we were writing them in the dark.

We did not know the amount of appropriations which would be available and were writing projects for personnel not yet on the staff. Certainly staff working on a project should participate in the formulation of the research problems.

I think the time schedule for RMA projects should be re-examined. Why can't the 9b1 and 9b2 funds be allocated to the Experiment Stations each year as other federal research funds? We don't have to write projects a year in advance to use Hatch or Purnell Act funds.

We may well be at a point in our research where we will have to take a new look at just what a project statement is. I think administrators and researchers alike have placed too much reliance in the project statement. It is considered to be a device to control and direct research and at the same time to be a research plan of work. I am confident we would be more realistic if we would develop some sort of a research agreement which would be recognized as nothing more than an agreement to proceed on a general line of work. A series of work plans and summaries of results could be used to give the administrator whatever control is necessary.

3. A marketing research program called for by RMA requires personnel. Nearly all the Experiment Stations have or could make one or two positions available in marketing. Certainly we have done our share to raise the salary of marketing research personnel. I believe the best solution to the personnel problem is to bring more general agricultural economists and even economists into the marketing research program, particularly those trained in prices.

In our marketing research program we are helped a good deal by graduate students. Some of our more promising graduate students who have completed all requirements for their degrees, except the thesis, have been employed on full-time research for the duration of a specific marketing project. We have conducted several research projects in this manner which we think have made significant contributions both in research results and in better trained graduates. Some of these students could not have completed their graduate training without such an opportunity. We realize the fact that these young men do not have much tenure and that we are slowing down some the rate at which our graduates become available for permanent positions.

4. I suspect the most critical problem most of us face as a result of the RMA is that of defining significant and manageable research

problems in a line of work that is expanding so rapidly. The danger, of course, is that it is easiest to do more research on the same problems. We can always follow more agricultural products through the market and describe the functions, services, costs, margins, shrinkage, etc. I do not propose to set down a list of good and bad marketing projects. But I would be a little less concerned if more of our marketing research was designed to help improve our marketing system and more of our effort was directed at such areas as pricing arrangements, financing, and consumers' preferences.

The effectiveness of the research program of any organization will rest with the staff—not the administration. The marketing staff member who can locate real problems, get some information important to their solution, and see that results are made available to persons or groups who are making decisions, is indeed a valuable person. We must work out democratic procedures for administering research. Attempts in this direction are being made at a few colleges and universities and I know one or two men in the U.S.D.A. who understand the idea. However, the idea that administration can be democratic is completely foreign to most of our thinking.

5. The rapid expansion of marketing research in most of our departments has had no counterpart in the other lines of research we are engaged in. It is quite natural for administrators to think the agricultural economics departments are doing well, and, hence, to use the 9b1 and 9b2 non-marketing funds in other departments. I suspect some of the responsibility for this situation rests with the staff. Actually non-marketing research in agricultural economics is authorized with 9b1 and 2 funds. The non-marketing staff have not been familiar with the Act and hence have not submitted new projects in the time pattern required by RMA.

Regional Research (Title I, 9b3)

Anyone from the North Central Region writing on the RMA should have something to say on regional research. For over 10 years now the North Central Region has had at least two very active regional committees engaged in research activities—The North Central Regional Livestock Marketing Committee and the North Central Regional Land Tenure Committee. Both of these committees have received active support from BAE, U.S.D.A. The livestock marketing committee has had one BAE person available

to coordinate the research.² The land tenure committee has had a number of BAE personnel work with it on specific projects. And, of course, the Farm Foundation has given the tenure committee continuous support. The Farm Foundation was instrumental in arranging for the first exploratory regional conference at Davenport, Iowa in 1938. Since that time the Foundation has paid, among other things, the travel expense of state technicians to attend at least two regional meetings a year. Regional committees came along rapidly in the North Central Region. The Poultry and Egg Marketing Committee was formed in 1940 and the Farm Structures Committee in 1944. Now we have eight regional committees concerned with agricultural economics research, six in marketing.³ Experiment Stations in the north central region have published 14 regional bulletins, seven on land tenure, four on marketing, and three on farm structures. The success of the regional committees on livestock marketing and tenure in the North Central Region was one of the major reasons Congress included provisions for regional research by Experiment Stations in the RMA.

In spite of this background of experience, I think regional research is the part of the RMA most difficult for the Experiment Stations. Let me illustrate again with our department. Our department participates in seven regional projects supported by 9b3 funds. Six are marketing and one is soil conservation. Seven of our senior staff are members of regional committees. One is chairman of his committee and chairman of the executive committee. Two others are members of their executive committees, one as secretary. Four other senior staff members serve with the regional committees in one capacity or another. This is a total of 11 senior staff members. As a minimum a member of a regional committee should spend several days once or twice a year attending the meetings. I would think he should spend some time preparing for the meeting and some time after the meeting carrying forward the program and decisions of the committee. The executive committee, made up of three or four members, is usually given the assignment of developing the project, recommending budgets, coordinating the research,

² Bjorka, Knute, "Regional Research in Agricultural Marketing," *This JOURNAL*, February, 1945, pp. 121-137, Vol. XXVII, No. 1

³ Cereal Marketing, Potato Marketing, Poultry and Egg Marketing, Livestock Marketing, Dairy Marketing, Fruit and Vegetable Marketing, Land Tenure, and Farm Management.

and editing the results. Major decisions are cleared with all state representatives. Members of these executive committees have quite a job. Decisions they must make are hard to make by correspondence. Hence, frequent out-of-state travel is necessary. Now for all six regional marketing projects our department will receive in 1949-50 about \$5,000 in 9b3 funds. This figure does not include regional funds (9b3) deposited with our Station for use of the regional "coordinators." You may say that it looks as though a small amount of regional money, acting as a catalyst, has stirred up a lot of activity at Wisconsin. The regional meetings have, I think, served as a stimulus to our research. On the other hand, most of the regional projects to date have not been enthusiastically supported by our staff if the amount of research done on the problem above the minimum regional requirements is an indication. I must say, however, that our department is planning to put about \$15,000 into research as a part of one regional project.

Although I am not familiar with the activities of our Station directors it seems to me they must be putting in relatively more time on regional research than on any other research program. One director is responsible for each regional committee and some directors have been assigned to several regional groups.⁴ The North Central Directors are meeting this week and I am told a considerable portion of their meeting will be devoted to regional research—projects, budgets, and allotments.

Regional research under the RMA has raised many of the same problems described in the previous section on state research (9b1 and 2). But, in addition, regional research has required relatively large amounts of time—both by staff members and administrators. Bookkeeping is excessive and project arrangements are complicated.

The real question before us is how to preserve the good features of regional research and at the same time reduce cost in personnel and money. We may find some of the RMA rules actually hinder work on regional problems.

I am in complete agreement with the logic behind the development of regional research in the RMA. The rules governing research workers in state Stations tended to limit their activities to the

⁴ *Definitions of terms and functions related to the organization and administration of Coop. Reg. projects . . . RMA. Memo. prepared by "Committee of Nine," Office of Exp. Stations, U.S.D.A., Aug. 1948.*

state. In many states technicians found it difficult if not impossible to travel outside the state. Many of the problems, particularly in social science, were common to several states and in some instances both research and improvement of the situation required the cooperative action of two or more states. Our North Central Regional Committee and subsequently regional research under the RMA were attempts to get research personnel from several states to work together on their common problems.

Generalizations are hard to make and often become meaningless. Yet here are some of the things I think Experiment Station personnel can accomplish by regional activity.

1. The competence of technicians will be improved. Technicians from several states working on similar problems will have an opportunity to exchange ideas and techniques.

2. Regional groups of technicians may bring valuable evidence to bear on regional problems without doing additional research. Previous research in the Stations can often be made the basis for important judgments on regional problems.

3. Regional groups can plan and conduct research together. I think there are three quite different types of research which can be carried on. One is in the nature of a regional census. This involves uniform schedules and the collection of similar data in each state. The second is a type of division of labor. Many problems are common to several states. If one state is doing research on one such problem then there is no need for additional work at another state. The third is research on a regional problem which will require regional judgment and regional action. This, I submit, should be the most important objective of regional research.

To date, however, very little of our regional research under the RMA has been directed to answering questions that must be answered as a region. There is some reason in this situation. A large segment of our devices available to do something about a given problem centers around our federal, state and local units of government.

I have described some of the regional activities we can and should carry on. Now let us return to the question of how to improve both the administration and the usefulness of regional research. As I have tried to point out the administrative machinery is costly in time and money. As yet the regional research has not been on regional problems, although there are some indications of

improvement. I am satisfied we should make some major changes in the rules. Here are my suggestions.

1. A series of regional agreements should be encouraged which spell out a general line of work. Funds should be allotted to these projects sufficient for the travel of technicians to regional conferences. This type of agreement should receive first priority in 9b3 allotments. The funds should be kept in a lump sum in the Station whose director is the advisor of the regional committee. This suggestion is based on my belief that most of the more desirable regional activities can be carried forward with existing sources of funds, provided rather regular regional meetings of technicians are possible.

2. If more specific plans of work are forthcoming for regional research 9b3 funds may be used in their support. These research plans should be carefully appraised to make sure the work cannot be done by other means. Certainly the plans should not have to be made a year before the research starts. There should be no attempt to use up a definite amount of money.

3. My third suggestion is that the full 25 percent of Sec. 9 funds need not be used for regional projects. If the research people do not develop enough regional research projects to use all of the funds the remainder will be distributed to the Experiment Stations under Section 9b1 and 9b2.

If we could follow the procedure I have suggested we would separate the funds used for the support of regional meetings of technicians and the funds used to do regional research. Combination of these two purposes has, I think, led to ill considered projects, especially where a definite fund has been set up and we try to use all of it.

DISCUSSION

M. T. BUCHANAN

State College of Washington

In my discussion of this topic I want to arrive at three major conclusions: (1) There is still a lot more to administering market research than is encompassed in various RMA funds and procedures (although properly the program committee and the participants have singled these out as the principal problems); (2) RMA funds are acceptable and can be utilized to advantage no matter what strings are attached; and (3) Committees are fine—in their place.

RMA sources of funds for marketing research were described by Dr. Joy. Leaving out the funds for utilization research, economists have a major interest in \$700,000 of 9b1 and 2 funds; \$371,050 of 9b3 funds, \$350,000 of 10b funds and \$3,800,000 of Title II funds. We are all glad to have these extra funds. Their proper utilization presents many challenges as has been pointed out.

We now have available in the Agricultural Experiment Stations a total of about 1.3 millions of dollars of relatively flexible funds as compared with slightly less than one million of 9b3, Title II and matching funds that might be classified as relatively inflexible in administrative procedures and use because of the unique problems associated with these fund sources.

Both of these sets of figures need some qualification—the flexible category by pointing out that considerable 9b1 and 2 and non-federal funds are tied up on regional or cooperative projects—and the inflexible by adding thereto some 10b funds allotted to cooperating federal agencies.

Nevertheless, at the moment, close to one-half of the total funds available for marketing research in Experiment Stations are relatively quite flexible. These funds constitute a very important segment of the total for good administration of marketing research.

While it is important that we continue to attempt to devise means of improving the administration of the various relatively inflexible RMA funds, practically we must realize that such funds are going to continue to be hedged in by restrictions and delays of one type or another. Let us then also adapt our marketing research programs to the funds available. This means, in general, (1) that we must look ahead at what the problems are likely to be three to six years hence and use inflexible funds for investigating these types of problems; (2) we must keep our flexible funds available for the “emergency” types of problems that arise; and (3) we should use a larger share of our inflexible RMA funds on “basic” research that will yield information that will be helpful for a wide variety of commodities, problems and circumstances.

Both Dr. DeLoach and Dr. Penn quite properly have given considerable attention to regional research. I am glad they have pointed out that some regional research was underway prior to the passage of the Research and Marketing Act and also that one of the principal contributions of the regional research procedure is to provide a means of bringing together technicians for a discussion of common problems.

I believe Dr. Penn should re-examine the regulations on 9b1 and 2 procedures. Titles and objectives, only, indicating the general nature of the work are required in advance by the Office of Experiment Stations at the request of the House committees on appropriations and agriculture. Similarly, the total 9b1 and 2 program, under present regulations, may be changed as much as 10 percent during the fiscal year for which funds are available. Projects under 9b1 and 2 funds that are not associated with regional or 10b cooperation rank next to regular federal grant funds and they in turn to state, receipts or gift and grant funds in administrative flexibility.

Barton De Loach emphasized lost motion in the west, but mentioned

that improvement is underway. May I agree on the lost motion, but emphasize the improvement? This has been stimulated by the Western Agricultural Economics Research Council both by discussion and by recommendations to the committees and to the regional directors.

It seems to me that this council, a sort of committee on committees for the western directors meets the qualifications of the proposal by Penn to finance such an endeavor out of 9b3 funds. The meetings are open and they are held either in conjunction with the Western Farm Economics Association or with technical committees.

Don't sell Title II short. Potentially it is a much larger source of marketing research funds than 9b3. At the moment procedures are not clear, it is difficult to determine what qualifies for support, matching funds are a problem, and "everybody in Washington, D.C. has to read and pass on every project proposed," but again improvement is in sight.

And, once more, do not neglect flexible funds. They are your ace in the hole.

The RMA by legislative direction and by administrative design has created and stimulated a rash of committees. Technical committees, councils, 22 industry advisory committees, policy committee, committee of 9 (8 old men and a nurse), ESMRAC. It's with committees as the entomologists say of bugs.

Big bugs have little bugs upon their backs to bite 'em
Little bugs have lesser bugs, and so on ad infinitum.

For the present let's classify them under only two headings—industry and professional.

First the industry committees. It's helpful to have them all meet at once. Spokesmen then work off a lot of their steam on each other.

By inviting industry groups to participate in research planning, and particularly if they get interested enough to put up some funds themselves, they become more interested in research. The big job in working with industry committees is to get their minds off their day-to-day problems and centered on a consideration of what will be useful five years hence. The wise research administrator will keep a little flexible fund sugar handy with which to be cooperative and handle some of the quickies. He will then encourage them to think long and hard about what are the basic, fundamental long-range problems.

Committees of professional workers have a real function in exchange of information; as a crucible for testing some untried or green ideas; as a means of bringing several specialized subject matter skills to bear on project planning; and as a means of raising the "norm" of research. Their big contribution is to be made in project planning—particularly what to undertake and how to start. From there on out our most valuable results will come from individual initiative and creative ability.

MAKING MARKETING RESEARCH USEFUL

F. L. THOMSEN

Production and Marketing Administration

IT WOULD be difficult to find a broader topic for discussion than the one assigned me for this round-table session. To make marketing research useful, it is necessary to (1) select significant marketing problems, (2) find solutions for them by applying adequate research methods, and (3) carry through with effective service and extension activities to insure practical application of the results. These three categories comprise just about everything in the administration and execution of marketing research, extension, and service programs. It is necessary, therefore, to limit my remarks to a few broad phases.

Right now about 50 percent of the consumer's dollar goes for production; 50 percent for marketing. If differences in efficiency of organization and management among individual marketing agencies are comparable with those among farmers, and if opportunities for technological improvement are as great, as I believe they are, we have no reason to anticipate a lower potential of improvement in marketing than in production. On the contrary, marketing offers the additional opportunity of improvement through changes in the *system* of marketing, as opposed to the efficiency of individual units, which is present in comparatively limited degree in agricultural production.

Some people say that the possibilities of improvement in marketing through research by public agencies are comparatively limited because the farmer has very little control over his products, once they leave the local shipping point. To me, this merely indicates the narrowness with which the scope of marketing research, service, and extension activities is viewed by many. The statement is valid only if we limit our research and other professional activities in marketing to those phases with which the farmer himself must deal. Actually, in order to encompass within our program the vast bulk of important marketing problems, we must be concerned with the marketing problems of marketing agencies far removed from the farmer. Our task in securing marketing improvement is largely that of effecting appropriate action by marketing agencies, not farmers. I believe that is possible, if we do effective research, extension, and service work directed at the operating problems of those agencies.

Some time ago, I addressed a few rather critical remarks in the *JOURNAL* of this Association toward what seemed to be rather obvious weaknesses in our agricultural marketing research. Along with some very nice bouquets, I received a few brickbats from colleagues whose sensitive skins apparently were allergic to frank criticism. To me, this is discouraging. Criticism, dissatisfaction with the status quo, a constant seeking for improvement, is the essence of science and of research. Are we to apply this searching analysis only to the marketing system, and not to our own policies and methods as researchers? Other sciences are constantly on the alert to improve methodology and results. Marketing researchers, if marketing research is to become really useful, must likewise be willing to put themselves under the microscope for periodic self appraisal and constructive criticism.

This is all the more important now that Congress has launched us upon a much more extensive and intensive program of marketing research, through the Research and Marketing Act of 1946. In my opinion, if this financial support is to be continued and expanded we must take the steps necessary to make our marketing research really useful, or the funds will be reduced or diverted to other subject matter fields where useful results are obtainable.

We have built up a considerable knowledge of what the marketing system is and how it operates. This knowledge, arising from a multitude of descriptive research projects dealing mostly with the comparatively unimportant aspects of marketing with which the farmer comes directly in contact, has prepared us to teach elementary courses in marketing and to counsel against wild-eyed marketing schemes that reflect a complete misunderstanding of actual market conditions. But it has not constituted a basis for important constructive improvements in marketing. We have built a foundation without continuing on to erect the house upon it. Yet we have been at this business for three decades or more, and can no longer cite the infancy of our science as an excuse.

I find, in discussing this subject with colleagues, a distinct tendency to confuse the "pure research" of the physical sciences with the sort of descriptive research we have been doing in marketing. It is pointed out that many of the most useful physical discoveries have resulted accidentally from research undertaken with no thought of useful application, or from later applied research based on the foundation laid by pure research. The atom bomb is a favorite example

offered in support of this thesis. Without granting that these instances are the rule rather than the exception, and calling attention to the relatively large volume of applied physical research which is directed at specific problems, I would remind you of some fundamental differences between the physical and economic sciences which relate directly to this problem.

In the physical world, conditions and relationships remain generally fixed. Once the properties of a given chemical substance are discovered, the description generally remains good for all time. Hydrogen sulphide smelled bad in my college chemical laboratory in 1915, and it smells just as bad now! No pure science researcher correctly described the physical properties of a group of chemicals as of 1939, only to find the same research organization starting to do the same job all over again in 1948 because the description was out of date. Pure or descriptive research in marketing is different in too many vital respects from the pure research of the physical sciences to warrant the comparison commonly made.

If I were to list a large number of practical, important marketing problems, the solution of which might contribute substantially to an increase in marketing efficiency or reduction of marketing costs, I am sure we would find that to many or most of them researchers have given little or no attention. This reflects a good many factors, including the preference for descriptive research projects, the frequent lack of adequate training which marketing researchers need to deal effectively with the more complicated marketing problems, and the tendency to select projects which are safe, noncontroversial, and give promise of assured "success." If a researcher sets up a project to study "Some Economic Aspects of the Marketing of Nebraska String Beans," unless he is an awful dope he is sure of producing a bulletin containing some interesting if useless "economic aspects." But if he undertakes, even in cooperation with other researchers, to investigate the possibilities of reducing fruit and vegetable marketing costs by integration of buying and bypassing several layers of produce dealers, he runs into some really difficult problems of economic theory and research methodology, not to mention public relations. He may or may not wind up with a nice bulletin which can be added to the list he prepared for his next job application!

Yet, if we would get somewhere in marketing research, we must courageously attack difficult and dangerous problems. Administra-

tive officials must be gradually conditioned to giving support to such efforts. Researchers must prepare themselves to deal with problems requiring a higher order of training and ability than the simple descriptive studies of the past. And we must seek the cooperation of Congress, advisory committees, marketing agencies and the public generally in support for this kind of marketing research. All of this will not come in a day. It will require patience, perseverance, aggressiveness, and competence, over a long period of years. But of one thing I am sure: we will never make real progress on a useful program of marketing research until we set our own sights high enough to encompass the marketing problems which offer potential opportunities for accomplishing something worth while.

I wish that the time allotted to me permitted a review of types of subject-matter problems in agricultural marketing, and the specific changes of direction in project selection, which would, I believe, put us on the road to realization of the great potential usefulness of marketing research.

The second prerequisite for useful marketing research, adequate research methods, is a subject, and a big one, all by itself. All I wish to point out here is that on this score, too, we agricultural marketing researchers are not nearly realizing our potentials. Our standards of professional training and competence in marketing research are, in my opinion, far below those found in the physical sciences. In commercial marketing research, which has been making great strides of late, professional standards seem to have been rising much faster than in agricultural marketing research.

The suddenly expanded marketing research program created the very real problem of obtaining professionally qualified personnel. This situation might be expected to become rectified in due course, were it not for the difficulty of weeding out the untrained workers, and the more important fact that our educational institutions are still turning out very inadequate numbers of men well trained in marketing and research methods. Among the scores of recent graduates, having various degrees from B.S. to Ph.D., whom I have interviewed in the past few years, few gave evidence of real familiarity with the more important tools of research. Many even displayed little or no familiarity with elementary concepts such as the elasticity of demand or the frequency distribution. Few of them had more than vague notions about sampling problems in marketing

research and how to deal with them. The term, "controlled experiment," seemed as foreign to them as the names of the Greek cabinet. How can we expect anything in the way of sound research from these half-trained people, who have been hurried through a few semester hours of economic principles, elementary marketing and statistics, the while they were "broadening" the smatter of their knowledge with courses in land tenure, labor problems, and the like?

Effective marketing research, dealing with difficult and intricate marketing problems, is no simple task to be handled by those with a smattering of training in marketing, economics, statistics, and research methods. To make marketing research useful, we must make marketing researchers competent. That calls for constant raising of standards, both in research institutions and training centers. Recently I was invited to appear as guest lecturer at a special session for marketing researchers. One of the first things my friend, the regular instructor, said was, "Now, don't make it too technical. Remember, these boys are from various agricultural colleges, and anything not pretty elementary will go right over their heads." That remark epitomized everything I have been trying to say here about training for effective marketing research; as did another recent remark by a man who was responsible for employing some marketing researchers for responsible positions: "The main thing is to see that they have a good farm background and a good personality. They'll pick up the research part as they go along!"

But the selection of appropriate projects and the competent application of research methods will not insure the usefulness of marketing research. In many cases, the value of the research will not be realized unless it is *persuaded* into use by appropriate informational, extension, and service activities.

On the surface, that may seem to be a very trite statement. The general idea has been stressed some thousands of times by extension workers, editors, and others. But I wonder if we have ever stopped to think about what it means in connection with "extending" the kind of useful marketing research I have been talking about?

Our whole information and extension program, and many of our marketing service programs, have been set up with farmers as the extendees. Yet, as I have tried to stress, improvements in market-

ing generally cannot be put into effect by *farmers*, but rather depend upon action by *marketers*. It would be almost as logical to carry the story of improved farm production methods to railroad workers as to attempt to effect most potential marketing improvements by educating farmers alone. If we are to make marketing research fully useful, some ways of extending it to marketing agencies and consumers, as well as to farmers, must be found.

By this I do not mean to imply that we should set up a whole new extension service to deal with people engaged in marketing in the same way that the present service deals with people engaged in farm production. I do maintain that the psychology, backgrounds, habits, and economic situations of marketers differ materially from those of farmers, and that we will not get far in extending the results of most marketing research by using personnel trained only in farming and agricultural extension methods, or by applying some of the extension devices which have been successful with farmers. We need an approach new in many respects, adapted to the job of training marketing agency personnel. Even if time permitted I could not suggest many features of such a modern marketing extension and service program. It is a really new subject, considered from this standpoint, and all that can be done here is to highlight the need, for the consideration of all of us who are interested in making marketing research more useful.

I hope this broad and generalized, and perhaps too pessimistic discussion of the subject is not a disappointment to those who came here expecting to be regaled with some specific examples of useful marketing research. I understand that some others on the round table will make good that deficiency in my remarks. Even though generalities are nearly as unpopular as criticism, I felt that I could make the best contribution to our round-table discussion today by iterating and reiterating what I believe to be some of the most important considerations governing the future usefulness of our expanding marketing research program.

EXTENSION'S ROLE IN GETTING RESULTS OF MARKETING RESEARCH TRANSLATED INTO ACTION

J. Z. ROWE

New Mexico College of Agriculture and Mechanic Arts

HISTORICALLY, the Extension Service has always recognized its responsibility to farm people in the field of marketing education. This responsibility was pointed out in past basic legislation creating Extension work in agriculture and home economics. However, the passage of the Research and Marketing Act sharply focused this responsibility. The passage of this Act, it seems to me, should call for a revaluation and appraisal of Extension's activities in bringing the results of marketing research to bear upon our farm problems. In the past, Extension's efforts have largely centered upon marketing education at the farm and home and possibly with farm marketing organizations, especially cooperatives, at the local level. If the Extension Service is to shoulder the larger responsibility as outlined in the Research and Marketing Act, it will be necessary to enlarge both the areas in which we work and the clientele with whom we work. In our marketing educational work, we must not only make contributions toward the application of research at the farm and home, but we must go further and develop techniques and methods so that marketing research will be of benefit in areas beyond the local situation.

Research into the multitude of problems affecting marketing and consumer education was also given impetus by the passage of the Research and Marketing Act. How quickly the Extension Service can expand its marketing educational work will be determined in a large measure by how quickly the results of research become available and how rapidly Extension can expand its efforts in disseminating the research findings available.

Although we do not have the vast background of marketing research that is needed for many problems, there are sufficient data and experience through which to attack a few specific marketing problems. It is true that most of this data must find its application at the local level. However, this is not unfortunate in all respects. In order to implement an expanding program in marketing education, more personnel will in all probability be necessary. This personnel will probably come from new and young workers. They may

have had varying amounts of academic training in marketing, but they may have had little experience. Thus, as new workers gain confidence and experience in working with marketing problems at the local level, the worker can move on with experience and accomplishment behind him when more research in the larger areas becomes available. The application of marketing research, it seems to me, has special problems. Consequently, in order to maximize the usefulness of marketing research, it should be made available as soon as possible.

In order to picture more concretely how one Extension Service has approached the problem of taking the results of marketing research to the field, perhaps it would be well to outline the procedure taken in New Mexico. We based our program upon the needs of the people. It was felt that in this work, some indication from the rural people of New Mexico would be worthwhile in crystallizing our thinking on a problem approach to marketing. Our county agents were asked to determine as nearly as possible from planning groups and others what problems were of most concern to the rural people in their county. From these suggestions, some twenty major problems were determined.

These suggestions formed the basis for planning our marketing program as well as the entire Extension program. They were examined to determine, first, if we had enough research background in order to develop effectively an educational program and, secondly, if our resources, especially with respect to personnel, were adequate to apply effectively research findings to the problems submitted. As a result of the appraisal using these as criteria, some problems had to be deferred as needing more exploration while still others presented opportunities upon which we felt we could develop an objective marketing educational program.

After culling and selecting, project statements were written for eight projects. At the present time, we are actively carrying on work with only five projects. In drawing up these projects, experiment station personnel and, where appropriate and available, other groups and organizations were called upon to participate actively in planning. I might add, these same groups still are an important part of our marketing program. We call upon them from time to time in discussing the progress of the work and ask for their suggestions and recommendations.

In determining just which projects would receive attention first,

a priority was given to each project. Priorities were determined by how frequently reports from the counties indicated need and by our opinion as to our ability to do the work.

We believe that the marketing program is just a part of the overall Extension program. Such being the case, wherever possible, all members of the Extension staff make their contribution to the program. Subject matter specialists of the particular commodity under consideration are technical supervisors. The Extension Economist is charged with general supervision of the projects. The work done on marketing, whether it is our regular marketing program or work in connection with RMA projects, is centered around the county agent's office. We believe that he is the important cog in contributing toward effective marketing education and, that he is vital in expanding Extension opportunities in the marketing field. This means that we must develop programs which will give marketing training to agents and supply them with information which will assist them in the solution of local problems.

The marketing work we are doing for the most part has been localized but we feel that this work must be expanded to larger areas for maximum accomplishment. Those regions which are the most important from the standpoint of volume of production of the commodity concerned and where the problem is most pressing are receiving major attention at the present time. Our workers in marketing did not rush into the program, but they spent time in talking with producers, handlers and consumers. We felt that by getting well acquainted with the area, the people and its marketing institutions, we could be upon firmer footing. Because farmers and the trade have been contacted previously on the particular marketing problem involved, the acceptance of the Extension Service as an educational force in the marketing field was spontaneous for the most part. It seemed that both producers and the trade at the local level welcomed the opportunity for help.

In applying the results of marketing research, we are using the well established Extension methods. We have found these especially adapted in working with producers. We are stressing marketing educational work with our 4-H groups. It is our desire to develop within our farm youngsters an awareness of the marketing problems involved in agriculture and present to them at an early age such findings as are available. In order to work more effectively with trade groups, in some cases we have found it necessary to be more

specific in demonstrating Extension Service techniques of education. We have found it effective to work through not only producer organizations, but also civic organizations such as chambers of commerce, service clubs and the like which have a high percentage of businessmen. The continuation of their confidence in our ability to work in the field of marketing education will depend upon how effectively we do our job. We must take the research findings and apply them in an educational way so that they may find practical application in everyday buying and selling.

The inevitable question might now be asked just what progress our educational marketing program is making. In view of the fact that all educational processes involve time, we are reassured with the progress we have made. I shall comment only on those projects upon which we are doing intensive marketing work.

The project dealing with the certification and identification of our long staple cotton has received outstanding backing by trade sources and farmers. In 1948, of the approximately 380,000 bales of this long staple cotton produced in the area under this project, almost 90,000 bales of 1517 cotton were tagged. Only 25,000 bales were tagged in 1947. Although the 1948 figure represents a substantial increase, it is still insufficient to be of any great commercial value. During this time we naturally found some factors which we believe contributed to a lack of fuller participation on the part of growers in the identification program. We have changed our procedure in order to eliminate these. Reaction to this certification and identification program has been especially good from spinners.

In working with producers and milk handlers toward the quality improvement of milk and cream, we also have received good cooperation. Although statistics are not available at this time showing the improvement of the quality of these dairy products before and since the marketing project was begun, managers of all three of the major milk plants in the area have indicated that the quality is higher than in previous years. Local sanitarians and inspectors as well as the state dairy commissioner have indicated that the project is showing unusual results in bringing about a higher quality product. The number of cans of cream rejected is down, sediment tests are improved and bacteria counts are lower. Grade A milk quality has been improved but reports seem to indicate that the greatest improvement in quality has been made in Grade C milk. We feel encouraged at this statement from the dairying industry

since last year we shifted our emphasis toward working more with Grade C producers than Grade A.

Due to the relatively unfavorable reputation of eggs from New Mexico, we are carrying on a project dealing with marketing quality eggs and consumer education. We believe that at least a part of egg quality consciousness on the part of producers and handlers is a result of this work. Assistance has been given to plant managers in the handling and candling of their eggs and in their storage problems. Perhaps of greatest significance is our work with buyers in an educational program directed toward the use of grades as a basis for purchase. Just recently one city in the eastern part of the state has begun a program to buy on grade. Grocery stores who purchase eggs from farmers are also buying on grade. In carrying on educational work with the consumers, we have been surprised at the large number of inquiries for information and requests for demonstrations on the various grades of eggs and their uses.

Our project on wool has met with enthusiasm on the part of producers but has not received the same response from the wool buyers. Upon initiation of our wool program, an attempt was made to skirt the wool. Working with the New Mexico Experiment Station in the spring of 1948 under the existing market conditions, fleece skirting did not seem advisable. Therefore, fleece grading at the ranch was emphasized. Grading of the wool at the shearing shed, we feel, has proven to be less time consuming and easier than at some point after the wool is sacked. Over 300,000 pounds of wool has been handled on a demonstrational basis since this program started. Since the grading of fleeces at the ranch is a new concept for New Mexico ranchers, we are devoting increased attention toward training county agents in this procedure.

A new project deals with the rating of rams. This is another new concept whereby ranchers may buy good sires sight unseen. We hope by the system of ram certification that a pool of desirable individuals might be obtainable in the state which will increase the return of clean wool per fleece. Already 155 rams have been certified as to clean wool production, type of body, staple and length of wool, degree of body wrinkles, and amount of face covering. Standards have been set up for all of these factors and grading and certification has been done accordingly. Interest in this program has already been manifested by buyers who need rams for use in their herds.

The newest project which we are just initiating is in the field of consumer education. We will direct practically all of our efforts toward working with urban groups. Best buys, selection and care of fresh produce, nutritional benefits of various foods and information on the food situation will receive major emphasis in this marketing work.

These are just a few highlights of our marketing projects and some indication of the progress we are making and the approaches we are taking. We feel that we are making progress but recognize that we are a long way from our complete objectives.

In conclusion, I would like to point out a few things, which in my opinion, will be necessary if both research and education in marketing are to show maximum accomplishment. First, I think it is extremely important that research and Extension personnel should work together as never before. Research and Extension should maintain a continuous two-way exchange of ideas. This would mean that Extension could keep research informed of changing conditions and new problems and research could furnish new findings for Extension to use in the field.

Research is needed by Extension at the local level. Also, in order to expand our marketing program to new areas and new clientele, we need research on national and regional problems. This would require an over-all approach to marketing without regard to political boundaries.

Extension, too, must find ways to attack regional marketing problems as research becomes available. State Extension Services must find means to bridge the gap that has for the most part restricted their activities to problems within their own state.

Extension must get new workers trained in marketing and enlarge the experience and training of present staffs. County agents, as mentioned previously, must be a part of this program and in many cases they must be trained.

Extension must expand its activities in working with the trade and consumer in this marketing work.

To broaden our marketing program presents a challenge and a responsibility. Without research, Extension marketing work will be ineffective; without Extension carrying the results of research to the field, much of the timeliness will be lost and effective application will be minimized.

EXTENSION'S ROLE IN GETTING RESULTS OF MARKETING RESEARCH TRANSLATED INTO ACTION

KENNETH HOOD

Pennsylvania State College

IN THE last few years we have been making considerable progress, largely as a result of increased funds made available by the Research and Marketing Act. The results of many new research studies are becoming available. Extension has increased its marketing force and is now engaged in translating these and other research findings into action. But we often feel impelled to repeat the last words of Cecil Rhodes, the great British-South African statesman, "So much to do; so little done."

The question before us is—How can Extension do a more effective job of getting research information used?

A close working relationship between Extension and research personnel is highly important. Extension men with their contacts in the field often are able to advise concerning research work that needs to be done. The research men can keep Extension informed about the progress of studies that are under way.

In many institutions, an Extension man serves on the advisory committee of each research project. It is also a common practice to hold periodic meetings of the two groups to exchange information on research findings and Extension teachings. County agents are brought into these joint conferences occasionally to present the viewpoint of those who are more closely associated with farmers.

Research personnel should be used when feasible in some Extension work. In this way they can learn what farmers and others engaged in marketing are thinking and what their needs appear to be. These contacts should help keep research on a more practical basis. Undoubtedly, there are many research studies that have been undertaken with little thought given to what use would be made of the results.

Marketing Specialists Need More Training

Many of our marketing Extension specialists are inadequately trained to do what is expected of them. Usually they have a working knowledge of statistics, accounting, agricultural prices and economics, but this is not enough. They need to know in addition

a great deal about the commodity with which they are working. There no doubt are some who would disagree with this statement, but there are many marketing economists who list this as one of their most serious weaknesses. One extension economist in the East who was turned into an egg marketing specialist was heard to remark "I was an Extension economist, but I am now a specialist in egg marketing and I don't know a thing about eggs nor how they are handled." His solution was a short leave of absence during which he worked with the egg trade.

Moreover, it is my observation that the best marketing work is done by those who specialize along commodity lines. The problems of milk marketing are vastly different from those encountered in the marketing of grain or wool. It is physically impossible for most men to be well informed about the peculiar marketing problems of many different agricultural commodities.

Marketing specialists sometimes fail because they try to do the job alone. Why not make marketing a project in which all extension personnel can play a part? Is it not true that marketing begins with production and ends with consumption?

The dairy specialist, the agronomist, and the farm management man as well as the milk marketing specialist are involved in the problem of how to get more fall milk in order to meet consumer needs during the months of low milk production. This is more than a job for the marketing specialist. Certainly feeding, breeding, management, pasture treatment and cost analysis have parts to play in this effort to smooth out the seasonal maladjustments in milk production to meet the needs of the market.

The marketing of potatoes begins with the production of the best varieties for the market and extends through proper care in digging to good grading and packaging and on through to distribution and food preparation. Here the plant breeder, the agricultural engineer, the marketing specialist, the nutritionist and many others are needed to produce and sell a good marketable grade of potatoes at a profit.

We Must Work with Individuals and Organizations

Sometime Extension fails to translate research results into action because too much time is spent in preparing reports, writing news articles and giving speeches and too little time is spent in working with those who have a marketing job to do. Extension

men must have contacts with farmers, consumers, cooperatives, wholesalers, jobbers, chain stores and others in the trade and *work with them*. We don't operate in a vacuum. Our information is only helpful in so far as we can get individuals to use it.

At the Regional Extension Marketing Workshop which was held at Pennsylvania State College in the spring of 1948, the marketing people in the Land Grant colleges were criticized—both research and Extension—for spending too much time at the farm level and too little in dealing with a solution of those marketing problems which arise in processing and distribution.

In an address entitled "Broadening the Field of Extension in Marketing Work," Edwin W. Stillwell, Vice President of the Farm Market Relations, Inc., said at this workshop:

"For many years experiment stations and the Extension Service concerned themselves only with problems relating to production. The development of Outlook reports expanded the horizon somewhat. Here and there real progress has been made in dealing with specific and real marketing problems. By and large, however, these organizations and the Department of Agriculture itself have worked with a "Chinese wall" which was erected at the wholesale level. Little consideration has been given to the problems occasioned by the movement of agricultural products to and through the retail store and into the paper bag—the last stage in the sale of the product to the ultimate consumer. . . . If the Extension Service really is to broaden its field in marketing, it is going to have to pierce or knock down this "Chinese wall." It is going to have to extend its teaching into the problems faced by the retailer and to consider the wishes and foibles and changing habits of the consumer. This is true because the consumer making his or her selection from among nearly 2,000 items in a modern grocery store is the one who determines finally whether the production of a commodity will be profitable or otherwise."

If we are to meet this challenge, we must move on into these comparatively unworked fields.

The marketing of farm products does not stop at the farm nor does it stop at state lines. Many times, the state marketing specialists have been handicapped in their efforts to follow commodities through to markets because these products move out of the state. Travel funds for out-of-state work usually have been drastically limited. The Research and Marketing Act with its provisions for regional work should prove of inestimable value to those who have an interest in working with people who are engaged in transportation, processing and distribution.

In late years, we have been entering vigorously into the con-

sumer education field. To be most useful here, we should not limit our activities to information on supplies, prices and consumer use. We need also to stress the costs of various marketing services and help consumers to decide how much service they want to pay for. It might also help consumers if they knew why they have to pay 21 cents for a quart of milk and 71 cents for a pound of butter.

Many times our Extension people limit their usefulness by assuming that the entire marketing field is theirs. Whether we like it or not, we must be ever mindful of the fact that there are many other agencies and groups carrying on educational work in marketing besides Extension. A good Extension marketing program is one that tries to secure the cooperation of these other people in carrying out a broad action marketing program that will be beneficial to all.

Another question that keeps being asked in our discussions relative to the proper use of research information is: How can we get the results before the information is too old to use? Research is a slow process and sometimes a long period of time elapses before the information is ready for publication. Would it be possible to make more use of preliminary results? Can Extension surveys supplement the more comprehensive studies of the research men?

So far in this paper we have been discussing the ways in which Extension can secure better results in the marketing field. In dealing with the problem at the farm level, there no doubt is a place for agricultural outlook and farm management information. With farmers, it's more than how to sell; it's also when to sell and what to sell. A knowledge of price trends, costs, seasonal influences, market preferences, consumer demand and governmental policy are all necessary if the farmer is to make wise marketing decisions. For many years, the Extension people at Penn State College have been combining marketing, agricultural outlook and farm management in one discussion. When this type of meeting is built around a commodity, it is very effective.

We Must Improve Our Methods of Extension Teaching

It is difficult for us to admit that our work in marketing is not reaching as many people as we had hoped. Can it be that we lack luster and appeal in our techniques?

Let's see how others attract the crowds and obtain a following.

Prizes, contests, acrobatics, dramatic skits, sound movies, glamour and human interest are all used to get people to come out to meetings and to hold their attention while they are there. Billboards, multi-colored posters, radio commercials, cartoons, attention-getting exhibits and advertisements well illustrated by highly paid skilled artists command the attention of the average American at every hour of his daily and nightly rounds.

Can we compete with these attractions and still tell our story in such a way that people will come to our meetings and read our marketing information? It is possible, but we must change our techniques to fit the times. We must use all media that are available for Extension teaching. Among these are slides, posters, exhibits, dramatic skits, sound movies, radio, television, news articles, envelope stuffers, well-illustrated talks, round table discussions, marketing tours and industry-wide conferences.

We'll have to improve our writing. Too much of our material is stilted and difficult to read. We write for the high school or college graduate and most of our reading public has never seen the inside of a high school class room.

We must make it easy for people to become better informed about their marketing problems. If we fail in this, many of the people who most need our help will never be reached and much valuable new research information will not be used to the best advantage.

Everybody from the farmer to the consumer gets very much interested in improving marketing methods and cutting distribution costs when prices start to sag and marketing costs remain high. We are indeed fortunate that we can go into this period of declining farm incomes and reduced business activity with a wealth of new market information. The question now is: How can we get enough men to do the big job that lies ahead? Frankly, there are not enough trained marketing people in the country to perform this task. We must train county agents, cooperative field men and directors, service men of private organizations, Vocational Agricultural teachers and local leaders to take a hand. Not all of these people can be used for all phases of marketing work as some of the problems are exceedingly complex and ever-changing, but we'll get nowhere by shrugging our shoulders and saying we cannot use them. The job is too big for the trained Extension specialists to do alone.

METHODS EMPLOYED IN AN ANALYSIS OF THE SPREAD BETWEEN FARM AND CONSUMER MILK PRICES IN NEW YORK CITY

E. C. YOUNG AND A. J. BERGFELD

Purdue University and Stevenson, Jordan, and Harrison, Inc.

IN MARCH, 1949, the New York State Temporary Commission on Agriculture released a report, "An Analysis of the Spread between Farm and Consumer Milk Prices in New York City under Present Practices." In this paper, which is based on the report, we propose to discuss the methods and special techniques which were employed in the study rather than the results.

Before proceeding further, however, it will be well to describe briefly the New York milk market and state the objectives of the study, since these considerations were responsible for the methods of study finally adopted.

Milk for distribution in the Metropolitan Area was received through 433 approved country receiving stations of which 343 were located in New York State. Eighty-one different companies or groups of associated and subsidiary companies shared the ownership of these 343 country plants. There were 21 fully integrated companies, i.e. with country plants, city pasteurizers, and routes. In 1947, 72 percent of the country plants included in the New York pool limited their operation to receiving, weighing, testing, cooling and trans-shipping milk.

Pasteurizing, Processing and Bottling in New York City

Except for a very small quantity of special milk, all milk and much of the cream distributed in New York City is pasteurized and packaged in approved plants in the marketing area.

There is little difference in the functions performed in these various classes of plants. The following classification is useful principally for purposes of describing the nature of the companies engaged in the business.

(a) *Plants operated by integrated companies which do little or no processing for others.* A large portion of the milk business is included in this classification. Most of the large companies in the group are self-contained. Included in this group are a number of smaller companies with wholesale outlets only. Frequently, they are somewhat specialized in their sales.

(b) *Plants operated by integrated companies which do a substantial business in processing and bottling for other dealers.* In general, companies in this class are (1) fairly large; (2) have a country supply of milk in excess of their own requirements; (3) offer a wide range of products and services; (4) have a wholesale business of their own but no retail routes.

(c) *Plants operated by companies with city routes but without a country supply of their own.* Companies operating plants of this type are generally smaller than average. Their supply of milk is furnished by other dealers or purchased from independent proprietary companies operating country plants or from cooperatives. Frequently, arrangements for the milk supply are negotiated through milk brokers.

Distribution of Milk and Cream in New York City

New York City's milk and cream is distributed to homes through 2174 retail routes and to stores, hotels, restaurants, and other wholesale outlets through 1626 wholesale routes. Most of the retail routes have A and B sections as a result of the introduction of every-other-day delivery in 1942.

In order to service areas distant from the plant and to avoid congestion in loading at the plant, depots are used in certain instances. With the advent of motor truck delivery there has been considerable decrease in the practice of using depots. Nevertheless, 39 percent of the retail routes of multiroute companies and 83 percent of the retail peddler routes originated at depots. Only 11 percent of the wholesale routes originated at depots. Depots are of three general types.

(a) *Depots of integrated companies serviced by the companies' own processing plants.* Packaged milk is loaded into vans and hauled to the depot, which consists of an ice box, office, and garage. The milk is loaded on to route trucks directly from the vans. It is distributed and accounted for in a manner similar to that employed when routes originate at the plant.

Each point of distribution, whether at a depot or plant, may have some depot functions. For example, a company with several processing plants may elect to produce a certain item at one plant only. This product then would be distributed through all branches, including those at other plants. Similarly, companies distributing from their own plant only and without outlying depots, may dis-

tribute items not produced in its own plant but purchased and delivered to it by another dealer.

(b) *Depots operated by companies without processing facilities of their own.* Most common is the depot operated by a small wholesale company which distributes a finished package of products purchased from or processed by one or more other dealers. The route trucks are loaded with all or the major part of their loads at the loading platform of the supplying company. Minor items are loaded from the ice box at the company's own depot.

(c) *Depots operated by peddler supply companies.* There were in 1948, 349 retail peddler routes in operation in the five boroughs of New York City. Usually the peddler supply company buys a finished package of milk or products from a company with pasteurizing and bottling facilities. This milk is van-loaded to the depot of the peddler supply company where it is reloaded directly from the vans onto the retail route trucks of the peddlers. The peddler supply company furnishes ice box and office facilities, bottles, caps and cases, and takes care of route returns. It maintains its brand name, exercises certain control over quality, advertises the brand, and provides a general supervisory function for the peddlers essentially similar to that provided in depots of fully integrated companies.

Of the milk which finally reached the consumer in homes in New York City, 28 percent was on home delivery and 72 percent was through stores in 1948.

The average prices paid by consumers for milk varied from a low of 20.6 cents per quart of plain milk for non-advertised brands in stores to a high of 24.9 cents per quart for advertised brands of homogenized milk at home delivery. The principal variables are: (1) advertised brands and other brands; (2) plain milk and homogenized vitamin D milk; (3) glass bottles and paper containers; (4) one-quart and two-quart containers; and (5) retail sales through home delivery and through stores.

The difference between average home delivery prices of peddlers and of advertised brands was determined to be 1.8 cents for approved plain milk in glass quarts and 2.0 cents for homogenized Vitamin D milk in glass quarts.

There was little variation in the resale price of advertised brands, but independent distributors were likely to give price concessions

to consumers or merchants who took a large number of units per stop.

At retail, two large companies had most of the business. This milk sold at a premium over unadvertised brands. The remainder of the retail business was split among four smaller fully integrated companies, 27 small retail distributors, and 349 peddlers.

At wholesale, more uniform conditions prevailed, although the advertised brands of milk moved into stores at a premium price over unadvertised brands. In the wholesale business, four large companies had about 45 percent of the business. Twenty-eight smaller companies with their own pasteurizing and bottling facilities had about 45 percent of the business and 43 small companies without pasteurizers had 10 percent of the business.

This study of the "spread" in milk prices between the farmer-producer and the New York City consumer was undertaken to determine the costs borne and the profits earned by the various agencies engaged in getting milk from the farmer's platform to the consumer. It also was the expectation that facts would be discovered which would make it possible to effect economies in this process.

A brief review of the data just reported will suggest that ordinary statistical treatment will not serve. In the search for a method of study which would reveal the true facts with respect to costs and permit realistic and profitable comparisons, a determination was reached to make the analysis on a functional basis.

There are clearly defined jobs (functions) that must be performed in getting milk from New York State farmers to New York City consumers. Each of these functions must be performed in a similar manner whether by a fully integrated company, which performs all the functions, or by an independent proprietorship or cooperative, which may perform only one.

For each function a carefully selected sample was obtained so as to reflect: (1) size and location; (2) ownership; and (3) type of operation.

Functions Included in the Study

1. Country Hauling—the average cost of custom hauling was used.
2. Pool Service—actual assessments by the Market Administrator and actual payments to cooperatives were used.

3. Country Receiving and Shipping—detailed time and cost studies were made.
4. Transportation from country plants to city pasteurizers—actual costs were determined from companies' books.
5. Pasteurizing, Processing and Bottling—detailed time and cost studies were made.
6. Platform and Loading—detailed time and cost studies were made.
7. Depots—detailed time and cost studies were made.
8. Retail and Wholesale Distribution—detailed time and cost studies were made.
9. Distribution through Stores—a detailed study of stores was made to determine buying and selling prices for milk, mark-up of comparable items, volume of milk handled, and kind and amount of services performed.

Each of these functional cost studies was made in a manner to reveal:

1. Dollar costs for the latest 12-month period available at the time of study for each company.
2. Unit cost in hours of labor and quantities of materials, supplies, and services.
3. Median costs and range in costs among those performing the functions.
4. An explanation of differences in costs among those performing the functions.

Costs were allocated within the function according to uniform procedure. This was done by a careful analysis of money costs as reported on the company's books. Costs were determined and allocated to functions and to products on a basis of engineering studies of time, space, power, materials, and service utilization. For each function, costs were determined for each separate process. Product costs were determined for each identifiable product.

A preliminary field review of both the books of account and the methods of operations in country plants indicated that these costs could be expected to vary according to the following factors:

1. The volume of milk being handled in each plant.
2. The number of cans of milk per producer.
3. The age of the plant and its equipment.
4. Administrative overhead.

A stratified sample was selected on the basis of these factors which were expected to influence costs. The operations were time studied and the labor and expenses for a twelve-month period were summarized. The results of these calculations showed country plant

costs ranging from a low of .350 cents per quart to a high of .589 cents per quart. This beginning difference in spread required for country plants is equal to the profits claimed by milk companies in their public statements.

City processing plants are highly mechanized in their pasteurizing and bottling procedures. Health department regulations establish a high standard for the cleanliness required for all operations. Total city plant labor and expenses, however, were found to vary by as much as one and a half cents per quart. Varying pasteurizing techniques, different bottling speeds, different degrees of labor utilization, and varying practices for loading and checking the trucks were found to be criteria for cost differences which again were used as the basis for selecting the stratified sample to be included in the survey.

Truck distribution to private homes, to stores, and to restaurants creates more cost per quart than any of the other functions between the farm and the consumer.

Detailed time studies of several thousand home delivery calls showed significant differences between the costs incurred in delivering to various kinds of customers. Consumers living in fifth floor walk-up apartments and receiving only two units with each delivery call and requiring weekly cash collections by the driver create obviously greater costs than consumers living in row houses taking four quarts with each delivery and paying their milk bill by check once a month. Any audit pooling of these varying conditions into an average cost per quart obviously obscures many of the causes for high costs of distribution.

A basic difference in procedure was also recognized. Some companies spend as much as \$7.67 per route day for selling and administration functions on their routes. Other routes are operated by individual entrepreneurs who own their own trucks and whose expense for selling and administrative functions can be evaluated as low as \$.94 a day. The economic justification for selling and administrative expenses in the amount of \$7.67 was brought under scrutiny because routes so administered served only 135 customers a day with an average of 2.86 units per delivery. The individual entrepreneur, however, who combined selling and administration with the physical work of milk delivery served 177 customers per day with an average of 2.83 packages. The differences in consumer buying habits and company operations combined made a difference

per quart of almost 3 cents in the cost of distributing milk to homes.

This functional analysis of home delivery also clearly indicates that home delivery costs are created as a given amount per customer call rather than as a given amount per quart. No significant cost difference could be found between serving a four-quart customer and a one-quart customer.

Store distribution costs were found to require similar detailed time study and cost observations. Some food vendors require daily cash collections by the driver as well as extensive in-store services, such as arranging the milk in the ice box and accounting for returned deposit bottles. Other store-keepers pay their bill once a month by check and do not permit the drivers to enter the store ice box under any circumstances. Some stores carry as many as four brands of milk and, therefore, require service from four individual companies each day. Others limit their milk purchases to two brands of milk and, therefore, have higher purchases from each of these two than if their milk volume were distributed among more dealers.

Delivery costs to stores, as a result of these differences in practices, varied by more than one cent a quart.

Profits per quart for distributing to homes ranged from a profit high of 1.3 cents per quart to a loss per quart of .8 cents. Including differences in selling prices, packages and products, store distribution functions showed a range from 1.6 cents profit to a loss for one enterprise of over 2 cents. These facts indicate the difficulty in attempting any generalization regarding the unit profit available for all companies under any given amount of spread. Evident also is the impracticability of attempting to lower the spread for the distribution of milk by a universal reduction in profit across the board. If the combined audited unit profit of all participants in the functions between farm and consumer were to be eliminated, very little could be accomplished in reducing prices to consumers or in increasing producers returns. However, substantial opportunities for consumer price reductions are within reach by having all participants in the spread emulate the most efficient practices and methods which are now in operation.

The combined procedures of functional cost accounting, time study analysis and market analysis do provide opportunities for searching step by step for those things which can be eliminated

from the spread and can bring the prices to producers closer to the prices to ultimate consumers.

Once the functional costs had been determined, the problem still remained as to how they could be presented. At one time it appeared feasible to present the array of costs within each function and select from this range certain measures as, for example, the median and first and third quartiles. These measures could in turn be presented in a cumulative series so as to report the absorption of the spread among the various functions.

Two principal difficulties to this procedure developed because of the nature of the New York market.

1. The spread differed among the distributors. Although milk was bought by all under a uniform price plan there were material differences in the cost of milk because of variation in fat content, transportation costs, premiums, and the like. Also, there were substantial differences in selling prices as between brands.

2. Each recognized function had been clearly differentiated from others. In each instance, cases were studied in which the particular function was the only one performed by the dealer or handler. Nevertheless, the complete functional analysis introduced an element of unreality since in practice most of the distributors carried on the various functions in a pattern of operation which involved considerable interdependence among the functions.

To meet these difficulties the results were finally presented company by company in parallel columns with the functional costs for each company displayed for comparison.

Other methods of analysis and presentation were considered. The time studies by functions could have been refined by detailed motion and methods analyses but this refinement might well be the objective of another study after the large opportunities for cost and price reductions made possible by adopting changes in the general practices have been accomplished.

Similarly, a model plant on a theoretical basis might have been developed from the information available from the case studies. This, too, may be the objective of another study.

With the method of analysis used the profit (or spread available for use and risk of capital) was the residue after all functional costs had been absorbed.

Had the determination of profit been a primary objective of the

study, the traditional audit method would have served better. This method places emphasis on end profit results, as shown by completed calculations, and a large gross sample is within reach at reasonable survey costs. The profit experiences of the participants can be related to the amounts of sales revenue, invested capital, and other indices of risks to establish a basis for moralizing about the rewards which are enjoyed by those who perform the essential functions. The combining of the audit results, however, assumes a uniformity in costs and in prices which may be contrary to fact. Assuming a uniformity in costs and prices also implies a uniformity in the methods, procedures, and arrangements by which the functions are accomplished.

Any method which undertakes to treat results of studies of this type by ordinary statistical procedures will encounter difficulties. The case method of study applied to a stratified sample appears best suited for either the audit or functional cost method. When the entire operation of assembling, processing, and distributing milk is broken down into segments, whether they be operating subdivisions or functions, statistical treatment is simpler. As the businesses are broken apart for study, the parts of the various companies bear a greater resemblance to each other than do the the companies when compared in their entirety.

THE MIDWESTERN EGG PROJECT

HERMON I. MILLER

Production and Marketing Administration

A STUDY of the deterioration of egg quality in marketing channels in 13 Midwestern states was undertaken last year by the United States Department of Agriculture and the agricultural experiment stations of those states. The project had three principal objectives:

- (1) To ascertain the quality of eggs at the time they are marketed by producers.
- (2) To determine the change in egg quality that occurs during the time that the product moves from the country buying stations to the central assembling plants.
- (3) To analyze market practices that influence quality change.

A Technical Committee provided guidance for the project. This Committee consisted of a representative from each of the 13 experiment stations, and a representative from each of the Federal agencies. The Technical Committee requested the Poultry Branch to act as coordinator for the project, and assigned the Coordinator the responsibility for developing suggested procedures and survey forms. Final decision on the scope of the project was made in November, 1947. Field work actually began in February, 1948.

Two steps in the procedure I think are worthy of consideration here. The first was the development of a work project outline which indicated in detail what, when, and how each cooperating agency would do the work which it was best fitted to do. The second was a meeting held in each state, to which the project leader invited all those who might be interested in the project—representatives of the State Department of Agriculture, Federal-State grading personnel, research, Extension and teaching members of the poultry husbandry and agricultural economics departments, and in some instances the State Agricultural Experiment Station directors. At this meeting, the objectives of the study and the work plan were discussed in detail. Insofar as possible, the sample of egg handling plants to be included in the study in each state was determined, and questionnaires, which previously had been prepared in preliminary form, were discussed. My own feeling is that this series of meetings was one of the important steps that contributed to the success of this regional undertaking. The research worker in each

state had complete support of his Administrator, the Extension workers, and others interested. Anyone within the state who was interested in the project had an opportunity at this meeting to contribute to its development. I strongly recommend these two steps in the development of all regional projects.

The work plan called for obtaining, as a first step, records of so-called egg concentration plants in the 13 states—plants where eggs are assembled for carlot shipment. These records were obtained by members of the Poultry Branch. The sample drawn consisted of 235 plants of this nature, well scattered throughout the region.

Information was obtained from the carlot assemblers about the buying stations that supplied them with eggs. The state agricultural experiment stations surveyed a sample of about 830 from the list of buying stations secured in this manner. The next step was to determine the grade of eggs moving through this procurement system as follows: In April, to represent the spring flush egg-production period; in July and August, to represent the hot summer months; and in October and November to represent the season of short production and high prices.

The services of the regular grading and inspection personnel of the Federal Department were used to determine egg quality. Each case of eggs inspected at a country buying station was identified with a sticker. The buyer was asked to handle the product in the usual manner, and when the sample of eggs which had been graded at the buying station arrived at the central plant, the same person was there to re-grade it. As previously indicated, this procedure was repeated three times during the year. During the three seasons we obtained gradings of 7,267 lots of eggs. The producers were identified on about 3,500 of these lots.

In addition to the field survey work the Bureau of Agricultural Economics obtained in April and in August, through mail questionnaires, information direct from producers regarding their marketing practices. With this background it is possible to determine the significance of the findings of the quality analysis.

The Farm Credit Administration studied the significance of graded buying programs and their influence on producer and handler practices. This work was confined to Missouri and Ohio. The Committee felt that graded buying programs might be one of the procedures that should be recommended to improve quality, and that this investigation might contribute to the soundness of such a recommendation.

Some of the Findings

The Committee recommended that two reports be prepared. The first covers the grading aspects of the study. This bulletin was printed by the Michigan Agricultural Experiment Station. The second, which will be printed in restricted numbers, will provide a great deal of background information regarding plant volume, merchandising practices, procurement procedures, etc., and will indicate the relationship of these factors to quality.

In addition to these two reports, a short, popular-style publication will be prepared by the Production and Marketing Administration. It will summarize the results of the grading work.

Quality of eggs received from producers. The producer lots representing eggs from the entire region for the three seasons averaged 66.7 percent A quality or better. About 11 percent of the eggs contained in these lots were classified as stains and dirties.

The 13 states were divided into three sub-groups, as follows: The Lake States, which included Minnesota, Wisconsin, and Michigan; the Plains States, which included the Dakotas, Nebraska, and Kansas; and the Corn Belt States, which included Missouri, Iowa, Illinois, Indiana, Ohio, and Kentucky. When producer quality was studied according to these three subdivisions of the region, we found that the Lake States had the highest and the Plains States the lowest quality for the three seasons. The greatest difference occurring during the summer months. The Lake States also had fewer eggs which were classified as stains and dirties.

The information on producer quality was analyzed to determine what influence, if any, several different factors had upon variations in producer quality. The factors studied were: (1) method of delivery, (2) method of sale, (3) size of shipment, (4) color of shell, and (5) type of buyer. The most significant findings in this analysis were those concerning the method of sale—that is, whether the producer sold eggs on a graded or an ungraded basis. Eggs sold on a graded basis averaged about 70 percent A's, as compared with about 60 percent for those sold on an ungraded basis, and the graded eggs contained less than half as many stains and dirties.

Quality changes during marketing. There was considerable loss in the quality of producer-delivered eggs while they moved through the country buying station marketing procedure.

The number of A quality producer-delivered eggs declined by approximately 10 eggs per 100 as they moved through the country

buying station. The number of checks contained in the eggs delivered by producers increased by approximately one percent. It seems to me that this is one of the more significant findings of the study. In the past, considerable emphasis has been put on educational programs with producers to improve egg quality, but little attention has been paid to the decline of quality of eggs as they travel through the marketing process. The deterioration study will provide our Extension Service and interested trade associations with facts upon which to base educational programs with producers and handlers as well.

Several factors were explored with regard to their relationship to quality change. The most important factor was the time between the first and second gradings. The effect of time and temperature, of course, is very much interrelated in its effect on egg quality changes.

I want to suggest several things which I believe are necessary if a regional research undertaking is to be accomplished successfully.

First—the project must be one which is truly regional in nature—i.e. one where states have a common problem that can be solved or answered thru similar research or one where it is necessary for each state to participate to provide a complete picture of the area to be studied.

Second, there should be complete cooperation from all the research workers.

Third, a coordinator should be selected and given authority and responsibility. The coordinator should preferably be a person whom the State project leaders choose because of their desire to work with him, rather than because he represents a certain agency.

The coordinator should have freedom to travel throughout a region and not be restricted to working inside the boundaries of a single State. On this point, too, I think that oftentimes a coordinator is selected who has a full-time job within his State and who therefore cannot give proper attention to the work throughout a region.

And finally, I think it is very important for each worker concerned with the research undertaking to feel that he has had a definite part in developing work procedures and plans, and that he is in wholehearted agreement with them. The meeting procedure is one way to bring this about.

DEVELOPMENT OF REGIONAL COTTON MARKETING RESEARCH

WILLIAM A. FAUGHT AND D. GRAY MILEY
Mississippi Agricultural Experiment Station

THE Regional Cotton Marketing Research Project is conducted under the authority of the Research and Marketing Act and is subject to the over-all policies established by the Administrator of that act. The Technical Committee has assumed the authority for formulating policies for the cotton project in line with the over-all national policies and has accepted the responsibility for the operation and the development of the study. The Chairman of the Technical Committee and the Advisory Committee is responsible for carrying out the instructions of the Technical Committee and the handling of administrative questions.

Approaches Used

No hard and fast decision was made by the group regarding the type of regional research to be undertaken. They expected their first efforts on the project to be partially experimental in nature and to aid in determining the most productive approach to be used as the project developed. During the first phase of the study a uniform cooperative approach was attempted. During the second phase a looser form of collaboration or a coordinated approach was tried. At the present time the group has moved back in the direction of a uniform cooperative approach but certain problems will be studied under a coordinated arrangement. This shifting of emphasis from one approach to another can best be understood by briefly reviewing the development of the project.

Because of the delay in appropriating funds for the project and because of the shortage of personnel, it was impossible to develop specific plans for the first phase of the work until late in the 1947-48 marketing season. In January of 1948 the Executive Committee met with representatives of several of the cooperating groups and developed detailed plans for the first phase of the study. It was the desire of this group to develop a plan of work which would aid in delineating and classifying the problems of cotton marketing and in forming a basis for future planning of the project. In developing these plans, the group decided that certain basic information would be needed regarding the marketing practices in local

markets throughout the cotton belt and, therefore, a uniform or cooperative approach would be most desirable. The group also wished to investigate the extent to which the one-variety production program had affected marketing procedures and the study was conducted in such a way as to permit comparisons between communities which were organized for one-variety production with communities which were not thus organized. Uniform sampling procedures were decided upon and uniform schedules to be used by each state were adopted. In the development of the study, however, the uniform sampling procedure was not followed in all cases, either due to misunderstanding on the part of the cooperating states or because the representatives of these states felt that the proposed sampling procedure was not adapted to some local conditions. Also considerable variation developed in the interpretation of terms and questions included in the schedules. The delay in starting the project had prevented the establishment of a pilot study and even discouraged adequate field testing of the schedules. As a result, the schedules were not as well designed and the data secured not as useful as they might otherwise have been. These conditions made the preparation of the regional report more complicated and difficult and restricted the conclusions which could be drawn. Preparation of the regional report was delayed by the failure of some states to submit data to be included until many months after the field work was completed.

In the development of the first phase of the study several distinct but related problems presented themselves which warranted immediate investigation. If the cooperative approach followed during the first phase of the study were continued only one of these problems could have been considered at that time and the study of the remaining ones would have had to be delayed. Moreover, the states were not in a position to begin a belt-wide cooperative study of the cost and efficiency of marketing—the phase which was felt to be the core of the problem. Certain basic information regarding the marketing process was lacking, personnel needed additional experience, and certain research procedures needed to be tested. On the other hand if a looser form of collaboration were adopted and only one or two states worked on each of these related problems, some study might be given all the proposed topics immediately. The information developed in this way by each group of states would be supplementary to the information obtained by

other groups and it would not be necessary for all states to work on each problem. In view of the limited funds and personnel available and the pressing need for information on the several related topics, it was decided the best results could be achieved if a coordinated approach were followed and the efforts of the group were divided between the several problems. Some states, therefore, began a study of mill requirements and buying practices to determine the extent and nature of mill demand for cotton. Some studied the marketing of cotton identified as to variety and year and area of growth and investigated the possibility of expanding bale identification to a wider area as a means of improving marketing procedure. Others conducted a pilot study of means of reducing and increasing efficiency of marketing in order to develop and test methods and procedures which could be adapted by the remaining states in expanding this study in subsequent years. Still others devoted their efforts to an investigation of certain phases of one-variety cotton production which appeared to need further study.

The coordinated approach revealed information on a wider range of topics than would have been possible if the more restrictive cooperative approach had been used. By providing an opportunity for testing certain research procedures on a limited basis, this approach also enabled the group to discover errors in these procedures before they were applied to the entire region.

During the third phase of the study which is now under way, a combination of both the cooperative approach and the coordinated approach is being followed. Additional experience and the testing of procedures during the second phase of the project have enabled the states to plan and get under way a belt-wide study of the cost and efficiency of marketing cotton through various channels. Variations in marketing practices from one area to another revealed in an early study, suggested the desirability of approaching this problem on a belt-wide basis and of employing uniform sampling procedures and uniform schedules. In addition to the belt-wide study in which most of the states are cooperating, the study of some problems already under way are being continued. Some states which are cooperating on the cost and efficiency study will also do some further work on mill requirements and buying practices, the marketing of cottonseed, or one-variety cotton-production. Others will conduct detailed cost studies of certain segments of the marketing system to provide factual information regarding these seg-

ments and also to test various methods of conducting costs studies which can be used by other states in the further development of this phase of the project.

The group is aware that the study of cost and efficiency of marketing cotton through various channels will be an extremely difficult and complicated one. It is also realized that even under the most favorable conditions this study will require a number of years for completion and if it is to succeed at all, it will require the cooperation of a large part of each segment engaged in the marketing process. In developing the study the workers will need the constant aid of statisticians, cost accountants, transportation specialists, industrial engineers, and others. This is a very ambitious program, particularly in view of the continued shortage of personnel and funds and the lack of experience of available personnel. In spite of these many difficulties facing the group, it is believed the importance of this problem justifies starting the study at this time. The study can reveal information of great benefit to the cotton marketing system and if the group working on this project is given adequate time and funds to develop the study in a careful and detailed manner, a valuable contribution will be made toward improving the competitive position of American cotton.

Some Benefits and Problems

The studies already completed or under way have provided a considerable volume of basic information regarding marketing practices of producers and buyers in local markets and the operation of gins, warehouses, and mills. Information has been developed regarding the one-variety cotton producing communities which certain agencies have already utilized to a limited extent in developing their programs. Fragmentary information has been obtained on the movement of cotton from local markets to mill points and on the functioning of the agencies involved in this process. The direct results of the study, however, are of less importance than such indirect benefits as the training and experience provided research workers and the contacts which have been established with various segments of the cotton trade. Also of great value have been the testing of various research procedures and the determination of the procedures which promise to yield the best results. Unfortunately, procedures and tools of analysis have not been

developed in the field of marketing research to the same extent as in some other fields of agricultural economic research, but must be developed before very rapid progress can be made.

In the conduct of the study certain difficulties were revealed which are due to the character of marketing research and which are common to all research in this field. In the study of marketing the research worker comes in contact with a number of economic segments, many of which may be unfamiliar to him. Producers, buyers, representatives of transportation agencies, processors, wholesalers, and retailers may all be contacted. Neither the training nor experience of most agricultural economists has fitted them to work with all of these various groups. Each of these segments is possessed of its own highly specialized field of information and the researcher must have a considerable knowledge of each field if he is to develop his relationships and conduct the study efficiently. A knowledge of general economics is required, however, for proper interpretation and thorough analysis of data. In the past, relatively little emphasis has been placed upon training along these lines and the opportunity of gaining experience in this field has been limited. Certainly few working in this field at the present time possess all these characteristics and some of the time spent on the project necessarily has been devoted to the training of personnel. Heavy turnover of personnel has further complicated the problem of maintaining a staff that has the training and experience necessary to carry on the study.

Lack of cooperation on the part of some segments of the trade has caused considerable difficulty. Many members of the trade are hesitant to reveal information regarding the operation of their businesses. This hesitation may be due in part to the belief that the results of the findings might be disadvantageous to the trade, but it is also partially due to distrust of the researchers and fear that information regarding the operation of individual firms will be revealed. In the past, experiment station workers generally have not developed contacts with the cotton trade and buyers have no basis for judging the integrity of the workers. Work on the project thus far has demonstrated, however, that better cooperation can be obtained after the members of the trade and the workers become better acquainted. As the project has developed the researchers have become more familiar with their job, learned some

of the problems and the way of thinking of members of the trade, and are in a better position to explain the purposes of the work and to gain the confidence of the people being interviewed.

Some segments of the trade have also expressed skepticism as to the ability of researchers to be of practical aid in conducting their businesses. This skepticism has been partially overcome in those instances where trade representatives have been asked to *participate actively in the planning and development of the study*. These representatives have furnished suggestions which have made the results more useful to the trade and aided in securing better cooperation. Some workers on the project have expressed fears that this procedure would lead to trade domination and the use of the project as a propaganda weapon. Such developments as these must be guarded against but in the development of the cotton project thus far there has been no evidence that any segment of the trade has such inclinations.

Some of the important problems in developing the project which are related to its cooperative nature have already been mentioned. These include the difficulty of establishing administrative machinery, of determining the authority and responsibilities of members of the group, of obtaining uniform procedures in the several states, of keeping an agreed-upon time schedule. Considerable progress has been made toward the solution of administrative problems but questions still exist regarding certain phases which will require further consideration.

AGRICULTURAL MARKETING RESEARCH AT THE UNIVERSITY OF CHICAGO

O. H. BROWNLEE

University of Chicago

LIKE much of the current research in the marketing of agricultural products, the "Chicago project" is concerned with marketing efficiency. To be more specific, we are attempting to: (1) draw the outlines of a concept of marketing efficiency which is consistent with (and hence derived from) widely agreed objectives of economic policy; (2) apply this concept to a determination of the extent to which too few or too many resources are employed in producing marketing services; (3) identify the factors which tend to reduce the efficiency of the marketing system below its maximum (with given preferences and available resources and technology), noting particularly the influences which might be altered by public policy; and (4) describe (largely by means of statistical estimation) some of the relationships which are relevant for measuring efficiency and the importance of certain forces which influence it. In approaching this problem we hope to apply to marketing research those parts of economic theory which have proven useful in other areas of economic research. We also hope that, from our findings, hypotheses might be developed which may prove useful in research relating to sectors of the economy other than marketing.

In the following pages I shall try to make clear some of the basic assumptions underlying our analysis and describe in more detail parts of the project and some of the hypotheses which are being tested.

The Concept "Marketing Efficiency"

Any appraisal of economic institutions must be made with respect to some norm—an ideal situation or a set of situations which is considered to be the "best" of those situations which are possible. This ideal situation is derivable from (1) the value system of the society served by the institution being appraised, and (2) the beliefs (facts and things that pass for facts) describing the various situations which are possible.

The various possible production situations are definable given (1) the supplies of various resources and (2) the ways in which these resources can be converted into products. These two sets of

data delimit the various "production possibilities"—the various combinations of products which might be produced and thus the sacrifices of some products which might have to be made in order to secure more of others.

Assume that we can divide the products of the economy into

FIGURE 1

The points in the space OAB represent various "production possibilities." Any point on the line AB represents an efficient point in the sense that an increase in the flow of X cannot be obtained without a decrease in Y , and vice versa. At any interior point (say, point C), production of both X and Y could be expanded without any increase in the amount of resources used.

two classes—marketing services and non-marketing services (both commodities and services). With a given collection of resources and ways of converting resources into products, the set of "production possibilities" might be described as the convex set OAB in Figure 1. Any point in the space OAB represents a combination of the two classes of products which it is possible to produce. Any point not on the line AB —the boundary of the set—represents a situation in which more of one product could be produced *without* sacrifice of the other product, while a point on AB represents a situation in which some of one product *must be* sacrificed in order

to produce more of the other. The points on AB have thus been characterized as "efficient points."

Production of a combination of products which is not an element in the set of "efficient points" indicates that either (1) the best of available technologies is not being employed or (2) the combination of resources employed to produce a given amount of product is

FIGURE 2

The curve AB is the same as that in Figure 1. The curve I represents combinations of X and Y which are equally satisfactory to the community as a whole with a given income distribution (see footnote 1). Hence D , where X_1 of marketing services and Y_1 of non-marketing services is being produced, represents a position of maximum welfare.

not optimal. An improvement in technology can be represented as a movement of the boundary away from the origin.

If we know consumer preferences and the "best" distribution of income, we can select a single element of the set of "efficient points" and denote this element as the best combination of products. This element will also be one in a subset of product combinations which are equally satisfactory to consumers—a "community indifference"

curve (see Figure 2).¹ Any departure from this element (represented as a point of tangency between the line AB and the "community indifference" curve) would indicate that, with the given preferences and income distribution, consumers had relatively too much of some products and too few of others compared with what they prefer and could be produced. Since the preferences of various consumers are not identical, the element which denotes the best position may differ with each income distribution, there being a different "community indifference" curve for each distribution of income. Rather than specifying a single income distribution and hence a single element in the set of production possibilities as "best," it probably is tactically desirable to consider each element corresponding to any income distribution as equally desirable and to thus define a set of best positions. Judgments regarding the "best" distribution of income are thus deferred to policy makers.

Given this set of best positions, the concept of efficiency is obvious. An economic system is as efficient as possible whenever the flows of products are those in this set. The degree of economic inefficiency is thus the degree of departure from this set.

Factors Accounting for Inefficiency in Production of Market Services

It appears highly unlikely that the firms producing marketing services are using the best technology or are using the optimum combinations of resources for producing the present flows of marketing services. In the language of the previous analysis, the present production situation probably can be represented by an interior point rather than an efficient point in the set of "production possibilities." However, when one compares the marketing sector with

¹ By a "community indifference" curve, I am referring to a curve showing the combinations of two commodities which will leave each member of the community indifferent as to which combination is available to the community as a whole. Assume, for example, a community composed of two individuals, A and B , and having available flows X_1 of commodity X , and Y_1 of commodity Y at its disposal. Assume further that A gets X_A of X and Y_A of Y thus making $X_B = X_1 - X_A$ and $Y_B = Y_1 - Y_A$ available for B . If the amount of X is reduced from X_1 to X_2 , Y must be increased so that A is as well off as he was with quantities X_A and Y_A and B is as well off as he was with quantities X_B and Y_B in order that the new situation be equivalent to the old. Community indifference curves may intersect, since if the initial distribution of X and Y between the individuals were different and the preferences of A and B are not the same, the amounts of Y required to leave them as well off after the reduction in X as they were before will differ (Refer to T. Scitovsky, "A Reconsideration of the Theory of Tariffs," *Review of Economic Studies*, IX: 89-110 (1942), for an example of the use of the community indifference concept.)

the rest of the economy and examines the factors which account for departures from the boundary points, it is my judgment that the bulk of the marketing sector of the economy will be appraised as relatively efficient.

Let me emphasize that the above judgment is a tentative one made without adequate empirical investigation. It is one of the hypotheses which we are testing. A test which would be unquestioned by most research workers would require knowledge of all relevant production functions (not only in marketing, but in the rest of the economy as well), resource supply functions, and consumer preference systems. In addition, it would require knowing how production decisions are made and whether they might be improved. Such knowledge, if attainable, obviously is beyond the range of this project. However, it is my belief that considerable progress can be made toward appraising the economic efficiency of various sectors of the economy through examining data which are already available and from which can be estimated such factors as rates of return to various resources in various uses, the movement of labor and capital between industries, comparative conditions of entry of new firms, differences in required labor skills, degrees of risk, and other relationships which will present at least a sketch of relative efficiencies of various industries.

My tentative judgment regarding the relative efficiency of the marketing system depends to some extent upon a modification of the previous definition of desirable situations to take into consideration lack of knowledge about the future and the kinds of changes which may occur in the data facing those who make production decisions. With any given initial situation, the set of possible situations at any time depends upon decisions made in the past by the various economic units in response to their expectations regarding the future. Other factors not subject to control, however, influence the positions which actually could be achieved. It is possible to select at the present time, from the set of expected possible situations for some given time in the future, a subset which can be considered as most desirable. When the given future time becomes the present, however, this subset may not be the one which is in fact most desirable. Nevertheless, with the knowledge available at the time when the decisions were made, any course of action other than that chosen would have been considered as leading to results inferior to those expected from following the course which was

selected. Consequently, unless we are to damn the system for failing to perform something which it may be incapable of performing, we must examine and appraise the way in which production decisions are made in the light of the information available to decision-makers.

Assume that my judgment about the production efficiency of the marketing system was confirmed. Then, aside from the errors resulting from lack of information relating to possible ways of producing—errors which could be reduced by more widespread dissemination of knowledge relating to technological possibilities—greater efficiency in marketing could be obtained largely through institutional modifications which would reduce uncertainty. Some of the modifications required would necessitate costs greater than those imposed by the uncertainty which they would reduce and hence would not be feasible. Others, however, appear to be achievable at relatively low costs.

Among the latter are modifications which would reduce the uncertainties imposed by inflation and depression. The flexibility which it is profitable for the firm to maintain in order to meet the wide variety of employment and price level conditions which have prevailed in the U.S. during the past three decades discourages long-term commitments of the kind which would increase economic efficiency. While this is not the appropriate place to debate which measures relating to the stabilization of such variables as the general level of prices or unemployment should be used, it can be pointed out that such stabilization measures—whether they be flexible taxes, flexible wage rates or flexible government expenditures, for example—transfer the flexibility away from the firm to a part of the economy where the costs of achieving it may be considerably lower.

Reducing the variability in the supplies of certain agricultural products would reduce marketing costs both through its impact upon uncertainty and through the decrease in excess capacity of processing firms which it would permit. It is my judgment that costs of reducing the year to year variability in livestock supplies would be less than the reduction in processing costs which would result. The year to year fluctuations in livestock supplies are largely related to the variability in feed supplies—variability which could be reduced at relatively low costs by appropriate feed storage policies. Here, also, the flexibility which now must be achieved by the firm would be transferred to another sector of the economy—

the grain storage sector—where the costs may be relatively low.

Other potential institutional modifications which would reduce marketing costs include changes in labor arrangements within processing firms subject to wide variations in levels of operations. In particular, the range within which firms must operate in order to avoid paying overtime or for time not worked is too narrow, given the wide range of volume levels which may prevail and which cannot be accurately forecast. Modifications might be made which would not impose undue burdens upon labor yet would permit more efficient labor utilization.

*Inefficiency Resulting from the "Wrong"
Production Pattern*

A second class of divergences between actual and optimal conditions is the relative overproduction of some goods and services and underproduction of others. Although the assumptions underlying many of the current judgments are not clearly set forth, a basic one appears to be that too much marketing service is being produced; i.e. that if certain services were eliminated, marketing costs would fall enough to more than compensate the consumer (and also the farmer) for the loss of the service. This assumption may be correct for some marketing services. However, if applied to marketing as a whole, it appears to be in conflict with evidence gathered from analysis of family budget data which show that almost without exception, money expenditures upon a commodity rise proportionately more with increases in income than do the physical quantities consumed. Increase in money expenditure with physical quantity held constant reflects an increase in "quality" of the product as well as an increase in processing and in other marketing services. However, in cases where there were no apparent quality changes, most elasticities of expenditures have exceeded the corresponding elasticities of physical quantities.

While this evidence is not definitive, it suggests that marketing is a part of the economy which will grow relative to that part which produces the raw materials, because consumers prefer to add services as they get richer. Examination of the trend of shares of the national income attributable to various sections of the economy adds confidence to this forecast. Reducing the amount of services might lead to reductions rather than increases in marketing efficiency.

There may be factors in the non-marketing sector which would

induce production of too many marketing services. As long as there is relatively "free" entry of firms into producing the various goods and services, the economic system contains a means more or less automatic which discourages long-run structural maladjustments of the kind that lead to overproduction of some things and underproduction of others. Much of the marketing sector of the economy is relatively easily entered. Capital requirements usually are not large compared with those in other industries. Hence, there is not likely to be underproduction of marketing services for any prolonged period of time.

Whether or not there is relative overproduction of marketing services under these conditions depends upon freedom of entry into other sectors of the economy. If entry conditions in some sectors are restricted, relatively too many resources may be forced into the "free" sectors. It has been argued that there are too many farmers and too many small retailers—foodstore operators, shopkeepers, and proprietors of filling stations being examples. While it is true that money returns to labor in these sectors have been relatively less than in most other sectors of the economy (excluding parts of agriculture), it does not necessarily follow that the real incomes of the supposed excess of these small entrepreneurs would be increased if they were to move elsewhere. Since 1943, adequate opportunities have been available for jobs in other parts of the economy. If there has not been sufficient movement to equalize money returns to comparable skills, there is a general presumption that non-monetary elements of income are relatively high in these areas. In any event, if corrective action is called for, it would appear to be of a kind which would reduce the degree of monopoly in the non-marketing sector of the economy.

Efficiency and Income Distribution

So far I have said nothing about the effects of the marketing system upon the distribution of income and have evaluated efficiency solely in terms of effects upon total income. In view of the fact that much of economic policy is designed to change the distribution of income from that which otherwise prevails and that most policy disagreements revolve around differences in judgments as to what the distribution of income should be, this omission may be considered a serious one. This is not the appropriate place to debate the merits of increasing or diminishing farmers' relative incomes by means of public policy. It can be demonstrated that—whatever is

decided as the "best" income distribution—using the marketing system (through its influence on price) as a means of achieving it is not appropriate in the sense that the total income to be distributed will be smaller than if direct taxation and subsidization is employed. Production possibilities will be more favorable (more of some commodities will be produced without sacrifices of other products) or the bundle of commodities produced will be more desirable, or both, if the direct methods are used. Thus, if it is believed that farmers should have larger incomes, a more appropriate device for making the change is a tax upon non-farmers, the proceeds being transferred to farmers.

Empirical Estimates Relating to Marketing Costs

The more intensive empirical work which we are undertaking is an attempt to estimate the effects of fluctuations in hog supplies upon pork processing costs. In this study we have been fortunate in securing the aid of managements of a few meat packing concerns in helping us to determine what factors are important and hence what things we should try to measure. One firm has given us detailed data from which we hope to estimate production functions for two plants—one in which supplies are relatively stable seasonally and one in which there are rather wide fluctuations both seasonally and annually. From these data we hope to be able to estimate the production functions for the two plants. Other costs—such as storage costs—can be estimated from aggregate data.

To date, we do not know what inferences we can make regarding the industry as a whole from the estimates which we might make. The similarities in technical processes used in hog slaughter by various firms comprising the bulk of the industry suggest fairly wide application of the results obtained from only one firm. However, there are difficulties in interpreting the statistical estimates which can be made from firms' cost data, unless one has considerable knowledge of the ways in which various production decisions are made. For example, it might be that the firm has too little (or too much) curing capacity; that it could improve its estimates of the time distribution of slaughter and thus reduce overtime and the employment of extra gangs. If any of these conditions hold, the observed cost at any level of slaughter cannot be considered as the minimum for this level. Nor can "mistakes" necessarily be considered as random deviations from the "true" function.

Any short-run savings from reducing the magnitude of fluctua-

tions in hog supplies would, on a *priori* grounds, be expected to be smaller than the long-run savings. The costs of changing the pattern of farrowings would be smaller in the long run (supply functions for the resources being more elastic) and the reduction in processing costs would be larger, there being an opportunity to adjust numbers and sizes of plants to the more stable supply situation. Thus, if short-run costs in a given plant could be reduced by X percent as a result of more stability in hog supplies, long-run costs should be reduced by more than X percent, since new plants could expect to operate within a narrower volume range.

Measuring these long-run cost differences, however, is even more difficult than measuring the short-run differences. It involves knowledge of technology applicable to livestock slaughter and the manufacture of pork products which may not have been known to many firms and which if known, may not have been applied in the construction of existing plant and equipment because of the variability in supplies.

As a first approximation, one might assume that the production function for the packing industry as a whole in the long run is such that a one percent increase in slaughter could be achieved by increasing the resources used by packing firms by one percent. If this were the case, long-run costs per unit need not exceed the minimum unit cost of any plant now in operation. Further knowledge regarding the potential technology of packing operations may reveal an even larger potential cost reduction than that which would be estimated by the procedure described above.

Along with the estimates of the changes in processing costs which would result from various changes in the variability of hog supplies, we are also attempting to estimate the changes in hog production costs which would accompany the changes in the time distribution of farrowings. Here, again, the estimates may not be sufficiently accurate because of the lack of adequate data. However, analysis of farm records and feeding experiments will yield some clues regarding these costs.

Measures to Reduce Supply Variations

If one knew accurately the magnitude of the costs imposed by hog supply fluctuations, he could determine whether it is desirable to suggest action which would reduce them, and if so, which of the various possible courses of action would be most desirable. There is

a general presumption that if the costs imposed by these fluctuations exceeds the cost of reducing them, some private economic units would take steps which would further reduce these variations. For example, it might be assumed that the normal seasonal pattern of hog prices portrays a combination of the costs of variations to processors and farm costs of farrowing hogs at various times. If the seasonal price movement were greater, the time distribution of farrowings would be more regular. But, packers would not save enough as a result to be able to pay the higher prices during what has been the low volume periods. This argument appears valid—assuming that both packers and farmers have complete information with respect to costs of these variations. Movement toward less seasonality in hog production during and immediately following the war suggests that farmers have overestimated the costs of reducing the variability in hog supplies and that the problem is largely one of providing them with adequate information. Evidence that meat packers have lost money, in the long-run, as a result of pork storage operations suggests that the seasonal price variation has been too small.

As indicated previously in this discussion, annual fluctuations in hog supplies appear to be closely related to fluctuations in supplies of feed grains. This is particularly true at the fringes of the Corn Belt. It is desirable that feed grain prices change with the availability of feed grains in order to encourage their efficient use. And little can be done about changing the weather to reduce yield variations. However, variations in the amount of feed stored is a way by which the fluctuations in crop production could be absorbed without equivalent fluctuations in livestock output. It appears that the function of storage in absorbing fluctuations in feed production has not been exploited as fully as would be most efficient from the standpoint of the economy as a whole. A relevant question is, "Why has not the private economy utilized storage as efficiently as is desirable?" Here, again, uncertainty with regard to prices may be an important factor. While there may be grounds for public action to help stabilize feed grain prices through a public storage program (perhaps the ever-normal granary) and through extension of credit to farmers to hold grain on farms when crops are above average, it seems reasonable that the private economy would utilize storage more effectively if the general level of prices were more stable.

I have tried to outline the basic presumptions (I hope they are not prejudices!) underlying our marketing research and the kinds of empirical estimates which we are attempting to make. To adequately test all of the hypotheses which will be suggested would require more resources than are available to our project. However, we hope that some of the questions we will unearth will prove of interest to other research workers and that some of our procedures will have an application to problems other than those which we are attempting to solve.

DISCUSSION

BENNETT S. WHITE

Bureau of Agricultural Economics

Around the Department we include studies such as we have had presented here in the general category of costs and margins work. As I see it, the job of the marketing economist working in the margins and costs field, and the objective of margins and costs studies is to supply the facts, which are now largely lacking, with respect to what marketing margins and charges are, what services they pay for, how these services are performed, and what might be done to reduce their cost. On the basis of the facts which he finds and the analyses which he makes, intelligent policies and programs can be formulated. Marketing economists are under tremendous pressure to do this job and to do it quickly, and I am inclined to believe that studies in the cost and margin field constitute the heart of the RMA program.

Dr. Young's study of milk marketing costs and efficiency in New York City is one of the most extensive and thoroughgoing studies of its kind. I do not believe that economists have as yet devised a satisfactory basis for segregating the cost of performing an operation with respect to a particular commodity or service when the same resource or resources are utilized to produce a number of goods or services. This, of course, is the familiar problem of joint costs. As Dr. Young says, the combination of functional cost accounting on a uniform basis, time and motion studies, and market analysis provide the basis for a searching out of those methods, practices and services which account for the various marketing charges. In addition, by indicating differences in cost and efficiency between the various individual firms, his study shows how it should be possible for all participants in the spread to emulate the most efficient practices and methods which are now in operation.

The North Central egg project discussed by Mr. Miller represents a successful effort to coordinate the resources and interests of a number of states and federal agencies in the achievement of limited objectives. This study should provide a valuable basis for further work which should include demand studies designed to measure the breadth of the market for

eggs of improved quality, and other studies in which price premiums and increased incomes to producers arising out of the marketing of better eggs may be compared with the additional costs involved in effecting quality improvements.

The cotton project discussed by Mr. Faught portrays the difficulties involved in coordinating and bringing to bear the efforts of a large number of states in an attack on the marketing problems of a commodity which has a complicated marketing system. The experience of this group indicates that the oft-criticized descriptive type of marketing study is frequently necessary as a preliminary step to the delineation of marketing problems and the development of methodology for undertaking research on them.

The paper presented by Mr. Brownlee is one of a number of studies which the Bureau of Agricultural Economics is sponsoring at universities and private research institutions. Some of us feel that problems dealing with pricing, the allocation of resources, and the over-all effectiveness of the marketing mechanism are likely to receive too little attention as compared with specific studies of particular commodities, agencies and functions. I think that Mr. Brownlee's work to date illustrates that general theoretical formulations of concepts and objectives relating to marketing efficiency may not be so difficult. However, testing hypotheses requires the making of empirical studies of particular industries, functions, and institutions which involve him in difficulties of generalizing or "adding up" which are similar to the problems many of the rest of us meet when conducting studies with more limited objectives.

Let me now mention a few points more specifically concerned with the current meaning and future effects of studies such as have been considered today.

As far as the current situation is concerned, I think that there is little doubt but that the studies under way can be completed and people will gladly receive them and read them. Even the studies which do not go beyond measuring margins will have a decided educational value. We have observed that some groups are interested in having us carry on margins and costs studies as rapidly as possible along the broadest possible front, because they expect the studies to show gross inefficiencies or exorbitant profits in the marketing of farm products. On the other hand, some middlemen and their representatives are urging that margins and costs work be expanded and speeded up for an entirely different reason. They obviously are expecting that our studies will indicate that marketing processes are not over-costly in relation to cost rates for the factors of production and methods and processes available and that profits are not unreasonably high.

When we come to future usefulness and ultimate effects of cost and margin studies, I think that we are on less certain ground, and a considerable diversity of opinion prevails. For my part, I am guardedly or conditionally optimistic. It seems to me that there are two big questions. First, is it feasible and practicable on the basis of existing conditions to make comprehensive studies of what marketing charges and costs are and what might be done to reduce them for all or most of the major agricultural

marketing industries? This is going to be a formidable task if we go into it. We are just making a start. The field is comparatively new. In some cases techniques have to be worked out as we go. Industry cooperation is a problem. All of this takes time, and yet we are being constantly urged to get quick results. Furthermore, the cost will be considerable. If we are to proceed with these studies, we must have the patience, cooperation, and support of those who are interested in research designed to provide the basis for making marketing more efficient.

The second big question, it seems to me, is: Will the results of the studies be used? That is, in the longer run, will cost and margin analyses actually result in a reduction in marketing costs? Since margins and cost research is not intended to provide the basis for government control and regulation, we must depend upon private enterprise to apply the results of research. This means that business men must be possessed of the enterprise and incentives necessary to effect the economies and make the improvements in efficiency which research studies indicate are possible.

I believe that those who entertain the view that agricultural marketing costs can be substantially and quickly reduced for a wide range of commodities are doomed to disappointment. Consumers are demanding more and more services. I am aware that this is entirely aside from the concept of efficiency as such, which assumes that marketing services remain the same. However, the fact of the matter is that many people expect marketing research to result in an actual decline in the spread between producer and consumer. If, as it seems reasonable to believe, standards of living continue to rise, consumers can be expected to demand more rather than fewer services, and this will work against any reduction in marketing margins and costs. In fact, some of the marketing research under way at the present time, while it may be effective in demand creation, can be expected to increase rather than decrease marketing costs.

In the second place, well over half of the marketing charges for agricultural commodities are accounted for by wage payments. Wages have risen sharply in recent years and certainly cannot be expected to undergo any general decline. Not only are wages to remain high, but there is sometimes resistance to the introduction of labor-saving machinery and to changes in methods and practices because of loss of jobs for wage earners directly affected. This introduces the problem of the opposition of vested interests to changes in marketing methods and channels, which is, of course, much broader than labor and wages. This in turn brings up questions of price policy, the extent to which competition prevails, the rigidity of marketing institutions, government programs in the marketing field, etc. In my opinion, work along this line needs to be considerably expanded. It is extremely difficult, but results might be proportionately great. Research which points the way to methods, practices, processes and channels which would provide for lower costs and increased efficiency will be of little use if the institutional structure of the marketing system, price policies of private business, government programs, and related factors interfere with the application of the results of research.

The actual showing which research may be expected to make will also be related to general business conditions and price levels. It is a well-established fact that cost factors entering into marketing charges are relatively rigid and do not fluctuate in response to changes in the demand for and supply of agricultural commodities. As you know, there is a close correlation between the level of agricultural prices and the share of the consumer's dollar received by the farmer. A period of sharp decline or prolonged low prices for farm products would be certain to bring a marked decrease in the share of the consumer's dollar received by farmers, notwithstanding increases in marketing efficiency.

However, I think we are still justified in believing that studies designed to provide the basis for improving the efficiency and reducing the costs of agricultural marketing are very worthwhile. I think we are justified in believing that obtaining and disseminating the facts on marketing costs, in time, will make a significant contribution to lowering marketing costs more than otherwise would be the case.

CURRENT STATUS OF MARKETING AGREEMENTS FOR FRUITS AND VEGETABLES

S. R. SMITH

Production and Marketing Administration

THE Marketing Agreement Act of 1937 administered by the Production and Marketing Administration of the United States Department of Agriculture authorizes the use of marketing agreements and orders in handling enumerated products (including fruits and vegetables) in interstate or foreign commerce. The act has three specific objectives: To raise prices to or maintain them at parity; to protect consumers by authorizing no regulation designed to raise prices once parity levels have been reached; and to maintain minimum standards of quality and maturity.

Agreements and Orders

A marketing agreement is a contract between the Secretary of Agriculture and the handlers of any farm product. Authorized actions pursuant to agreements and orders are protected against anti-trust prosecution for combination or conspiracy.

A marketing order binds all handlers operating in specified production and marketing areas to adhere to its terms. Orders may be applied to milk and its products; to fruits and vegetables, except for canning or freezing—with a few exceptions; certain nuts; tobacco; soybeans; hops; and the products of these commodities, also naval stores and honey bees. Orders applicable to fruits and vegetables may provide methods for limiting shipments by grade, size, quality, maturity, and pack in specified markets for specified periods; for allotting purchases and sales by handlers; for surplus and reserve pools; for inspection; for defining and prohibiting unfair practices or methods of competition; for selection of administrative agencies; and for such other items as are necessary to administer the order.

Both agreements and orders—except for milk, which is not discussed here—apply only to handlers and not to producers or retailers.

Formulation

The Secretary may initiate proceedings, but usually a tentative agreement and order is formulated by industry groups, submitted

for preliminary approval to the Production and Marketing Administration, and then discussed in detail at public hearings which are conducted much like courts. Upon conclusion of hearings and with time allowed for briefs and exceptions to be filed, the Assistant Administrator of the Production and Marketing Administration and the Secretary of Agriculture must both approve the proposal on the basis of evidence in the hearings record.

Agreements become effective when in the judgment of the Secretary sufficient handlers have signed them. A proposed order, which must parallel an agreement on which hearings have been held, becomes effective when the Secretary finds from the record that it will effectuate the objective of the Act; that the production area is as small as practicable; that different production and marketing conditions among different districts of the production area are recognized in different provisions; and that after submitting the order to referendum of producers, (a) it is approved by two-thirds of voting growers by number or volume of production and the parallel agreement is approved by handlers of at least half the regulated volume, or (b) handlers have not approved a parallel agreement but at least two thirds of growers by number or volume have approved the order. Additional requirements are that the order will effectuate the purposes of the act and that there are no other feasible means of accomplishing such purposes. Programs are thus formulated by the industry; proposals are carefully appraised by the Department; all interested groups have a voice at hearings and the industry approves the program.

Development of the Statute and the Programs

Only four short provisions relevant to market control were included in the Agricultural Adjustment Act of 1933; namely, (1) the Secretary could enter into agreements, the terms of which were not specified, with handlers of any farm product to control its interstate or foreign movement; (2) he could impose licenses, the terms of which were not specified, upon any or all handlers to prohibit charges or practices which prevented recovery; (3) he could require maintenance and disclosure of books and records as necessary; (4) he could avail himself of the investigatory powers of the Federal Trade Commission in inquiring into compliance. Including milk, 68 programs using licenses were formulated. Thirty programs for fruits and vegetables were developed, the production

areas being heavily localized in specialty areas on the Pacific coast and in the Southeastern States. Twenty-two programs were still operating in 1935. Nine are still operating and some of them have functioned continuously.

Experience with agreements and licenses indicated that programs should be confined to areas as small as practicable in order to maintain homogeneity of interests, to facilitate local administration, to prevent regional or Nation-wide monopoly, to eliminate problems of interregional equities, and to make adjustment to local differences in production and marketing conditions. License programs have been attacked in courts in cases which alleged failure to adhere to due process of law, incursion into intrastate trade, delegation of legislative powers without adequate administrative standards, and invalid delegation of executive authority to control committees. As a result, most of the safeguards in the present Act were introduced in 1935, such as: substitution of orders enforced by courts for licenses which could be revoked; applicability of orders to enumerated commodities only; provisions for assessment and enforcement; establishment of committees as agents of the Secretary, in whom all executive authority was vested; provision for modification, review, or exemption from findings or penalties; authorized integration with state and with other Federal programs; specification of parity price as the objective and upper limit for programs; procedure for notice and hearings; definition of commerce to be regulated; restriction of terms in orders to enumerated provisions; essential identity of an order with an agreement on which hearings had been held; careful specification of conditions for approval, effectuation, and termination.

When the processing-taxes section of the Agricultural Adjustment Act was declared unconstitutional in 1936, the market control sections could remain effective only if separated from the production phases of the act. The agreements and orders provisions were therefore separately reenacted as the Agricultural Marketing Agreement Act of 1937. In 1947, one major amendment added the maintenance of standards of quality in the public interest as one of the three objectives and thus made it possible for grade and size programs not designed to raise prices to be operated without reference to the parity standard. The act is a permanent statute independent of relief or adjustment objectives.

Use of Marketing Orders

Since 1935, orders have been promulgated for bees, cauliflower, celery, citrus fruits, grapes, hops, melons, onions, peaches, pears, plums, lettuce, peas, potatoes, fresh prunes, tomatoes, and walnuts. Forty-seven orders have been issued for 37 production areas. Nine have governed more than one commodity. Eight orders have been effectuated without a parallel marketing agreement. No marketing agreements have been made effective without a parallel order.

In early August of 1949 there were 22 fruit and vegetable programs in operation and several others were being formulated. Four cover citrus fruits, eight are for deciduous fruits, one is for vegetables, seven for potatoes, one for walnuts, and one for hops. Three programs regulated more than one commodity, which is done only when the products are related, when most growers produce more than one and when the cost of operation can be reduced. Twelve production areas are on the Pacific Coast, four in the mountain States, three in the Southeast, and three potato orders in the central States and Maine. Eleven programs include more than one state. For citrus fruits nearly the whole domestic supply is covered. Thirteen orders authorize different regulations for different parts of the production area. Thirteen permit different regulations for different varieties.

Nearly any commerce now burdens, obstructs, or affects the flow of trade among the states or with foreign nations. However, several orders restrict regulations to the United States and Canada; a few are applicable only to continental United States, Alaska, and Canada, but in general interstate and foreign trade may be controlled. Six orders provide for different regulations to different parts of the market areas. Five orders date back to 1933. Most have operated more than 10 years. One-third have been amended. Most of them have weathered a depression, a recovery, a recession, a war boom, postwar inflation, and the present readjustment. The life and stability of these programs indicate that properly formulated and applied, and well-administered, they can benefit producers without damage to other groups.

Nearly two-thirds of a billion dollars of annual production is now regulated by fruit and vegetable orders. Nine programs affected more than 5,000 producers each, the farm value of their annual production ranging from \$25,000,000 to \$90,000,000.

Administrative Agencies

The ultimate goal of producer welfare is the reason that most control committees are weighted heavily with grower representation. The need to recognize handler interests and to utilize their skills results in inclusion of handlers either as voting members or as advisers to grower committees in most programs. Final authority rests with the Secretary, to whom committees *recommend* specific regulations for clearly defined markets and periods by the methods authorized in the orders. The Secretary has broad powers. He chooses committee members from nominees selected by the industry; designates agents to act for him and all acts of committees must be approved by him or his agent to become binding; he may remove any officer; suspend or revoke any regulation; he must approve budgets and assessments; he may substitute another agency for the committees; he may suspend all or part of a program if it does not contribute to the objective of the act. Nothing in an order may limit the rights of the Secretary to intervene. As a result, no committee member is held personally liable for actions under the order except those actions involving dishonesty, willful misconduct, or gross negligence.

Thirteen orders provide for a single administrative committee although informal subcommittees may be established. Six programs provide for handler advisory committees and two orders establish district advisory committees to assist in formulating regulations, but not to vote on them. Four provide for district committees to formulate district regulations subject to disapproval by the area committee. Membership ranges from six to 25 persons. Five committees are composed of growers only. Growers are given one vote each in one district in choosing nominees. Handlers vote for handler-members either personally or by relative volume of business.

At least a full majority of the committee is required to forward a recommendation to the Secretary. Some orders require a two-thirds vote. Membership is distributed by districts and by affiliation, with a neutral member sometimes included, to prevent any single faction of an industry from controlling either affirmative or negative action.

All committees are empowered to administer the order, to investigate violations, and to recommend amendments. They are

required to mediate between growers, handlers, and the Secretary; to keep books available to the Secretary; to analyze growing and marketing conditions; to make audits; appoint employees; to give notice of meetings, regulations, and policies; and to provide information requested by the Secretary. Some committees must publish monthly statements, make crop estimates, recommend changes in election or prorate districts, announce opening and closing dates for shipping, consult with other committees, undertake research or service work, or delegate limited authority to employees. Nineteen committees must promulgate, in advance of issuing regulations, a detailed shipment policy which will permit growers and handlers to adjust their operations to the contemplated regulations. Recommended regulations must be in accord with standards set out in the order and with the advance marketing policy, valid with respect to the act and consistent with its objective and in each case supported by data and analyses. Activities of committees are further governed by requirements of the Administrative Procedure Act, Department regulations published in the Code of Federal Regulations and committee bylaws.

The Secretary may authorize committees to collect uniform assessments for expenses which are reasonable and likely to be incurred, in accordance with an advance budget approved by the Secretary. Funds may be used only for purposes authorized by the order and such uses must be approved by the Secretary. Excess funds are either credited to handlers' accounts or returned to handlers at the end of each marketing season.

Methods of Regulation

No court decisions indicate precisely the scope of regulation which may be permitted under the broad provisions of the act. Many different methods have been used, but most of them may be classified within a few major types, namely: (a) *Regulation of quality*. This is usually accomplished by specifying the grades and sizes of the product which may be shipped to market. (b) *Regulation of quantity*. This method of regulation involves the establishment of the quantity of the product which may be shipped to market during any specified period. The total quantity is allocated among all handlers on the basis either of past performance of handlers or the amount of product each handler has available for

current shipment. (c) *Reserve pools*. This involves the establishment of a reserve pool of the product, and the equitable distribution of returns derived from the sale thereof. (d) *Surplus control*. This involves determining the extent of a surplus, providing for the control and disposition thereof, and equalizing the burden of surplus elimination among producers and handlers. (e) *Unfair trade practices*. A method may be provided for prohibiting unfair methods of competition and unfair trade practices in the handling of agricultural commodities. (f) *Price posting*. This involves the requirement that handlers file their selling prices, and such handlers are not permitted to sell at prices lower than such prices as filed. Handler may change the prices at any time, but adequate notice must be given thereof.

Limitation of shipments to particular grades and sizes has been authorized in 30 programs and 13 have provided for minimum standards. Two each have authorized limitation by grade only or by size only. Two each have provided for minimum quality and for minimum maturity and one has specified pack requirements. Seven have authorized control over rate of flow to market, two of these specifying daily control and four authorizing shipping or loading holidays. Six orders have provided for diversion to secondary outlets. One program provided for price posting, and two have defined and prohibited unfair practices and methods of competition.

Trade channels, trade areas, or outlets other than those specified are exempted from regulation. Fruits and vegetables for canning or freezing cannot be regulated by Federal orders, except for asparagus and olives. Charity, relief, express, parcel post, and minimum-volume shipments are usually exempted.

All orders require reports as requested by the committee or Secretary in order to check compliance, the fulfillment of the objectives of the Act, and the degree to which antitrust exemption is abused. Most of them require manifest reports with detailed information on each shipment. Standard forms are provided and the extent and frequency of reporting are minimized. Confidential matter is carefully protected against disclosure, by the law, by the terms of the orders, and by the regulations of the Department.

Enforcement

Three methods are authorized in the act: Civil damages triple

the value of overshipment; restraining orders or injunctions; fines of \$50 to \$500 after conviction in a criminal action. Most cases in recent years are outright violations and the infrequent fruit and vegetable action is usually prosecuted under the criminal-penalty section. Any handler may petition for relief from any order or regulation. While the petition is pending, he is protected against criminal prosecution. Procedure is outlined in detail for handling such petitions and for appeal to the courts from the decision of the Secretary. The agreements and orders programs are protected against whimsical or capricious administration by any person at all stages from formulation through the issuance of regulations by the Secretary.

Procedure for amendment is much the same as for formulation, except that less time for notice may be required.

All, or any provision, of an order must be terminated if the Secretary finds that it does not contribute toward the objective of the act. No regulation designed to raise prices above parity can be issued. On petition of producers of at least 50 percent of regulated volume, the Secretary must terminate the program at the end of the current season. Benefits, privileges, and immunities terminate then, except for acts committed during the operation of the programs. The administrative committees become trustees and liquidate the assets of terminated programs.

Summary

Agreements bind only signers and therefore are not effectuated unless parallel orders binding on all handlers are issued. Procedure for operations from initiation through formulation, effectuation, and issuance of regulation are specified in detail in law and in published regulations. Orders are applicable only to specified commodities and channels of sale. They may contain terms which have been used mostly for limitation of shipments to particular grades and sizes; minimum standards; rate of flow control; and surplus or diversion control. Agreements are effective as declared by the Secretary. Orders must be approved by the large majority of growers and usually by handlers. More than 60 programs have been effectuated since 1933. Twenty-two orders now govern marketing of an annual output of fruits and vegetables valued at about \$650,000,000. Grade-size control is most frequently used since it is equitable, easy to administer, and effective. Exemption clauses

prevent hardship to individuals or regions. Except for two western citrus industries, rate of flow control is used as an auxiliary to grade-size regulation. This method requires careful proration and provision for adjustment of allotment. Surplus control devices are used mainly for such products as nuts and hops. In general, the long life of these programs indicates that they are effective—when properly applied and administrated—in maintaining and establishing incomes to growers in the interests of the general welfare.

FLORIDA CITRUS AGREEMENT

H. G. HAMILTON

University of Florida

A DISCUSSION of the Florida Citrus Agreement should be prefaced with a brief account of the operations of the Florida Citrus Growers' Clearing House Association, because the pattern of government regulations was foreshadowed by this organization. The Florida Citrus Growers' Clearing House Association was incorporated under the cooperative statute of Florida and conformed to the Capper-Volstead Act. Federal and state agricultural workers, commercial people from within and outside the state, and growers all had a hand in its organization. However, as early as 1888, long before people outside the state became interested in the Clearing House idea, and from time to time after this date, the *Proceedings of the Florida Horticulture Society* refers to the desirability of a citrus czar, or an over-all organization, or some government program that would enable the industry to control itself. The objectives of the Florida Citrus Growers' Clearing House Association were:

1. Standardizing of grade and pack.
2. Prohibit movement in interstate commerce of poor grades and sizes.
3. Regulate weekly shipments to insure an orderly time distribution.
4. Regulate shipments to auction markets to insure an orderly place distribution.
5. Advertise.
6. Minimum prices or a floor under prices which would at least return cost of production to efficient producers.

The standardization of grade and pack program accomplished much and a good beginning was made in advertising.

Regulation of shipments to market and proration to auction markets failed for three reasons. First, those firms outside the Clearing House nullified the efforts of those firms in the Clearing House by increasing their shipments when the Clearing House decreased the shipments of its members. During one allotment period the 20 percent outside the Clearing House shipped 50 percent of the fruit. Second, when the non-members persisted in overshipping, members began to violate their allotments because they felt that they were left holding the bag for the non-members. Third, no equitable method of making allotments was ever developed.

The Clearing House never marketed or had direct control over a box of fruit. It attempted to achieve its objective by controlling the marketing firms.

Although at one time 80 percent of the Florida citrus crop was handled by firms affiliated with the Clearing House, it was short lived, operating from the beginning of the 1928-29 season to the Fall of 1933.

When Federal statute provided for a means of bringing the entire industry under control it was immediately endorsed by those who had supported the Clearing House movement as a method of accomplishing, with Federal law, what the industry for four years had failed to do on a voluntary basis.

On May 8, 1936, Marketing Agreement No. 64 became effective. This agreement provided for regulation of weekly shipments and grade and size restrictions. No provision was made for proration to auction as was the case in License No. 95. The basis of making allotments was changed from past performance to an option of past performance or current control. This agreement was thrown out by Federal Court order in 1937 after operating less than a season.

Order No. 33 Covering Florida Citrus Fruit

Since February 22, 1939, the Florida citrus industry has been covered by Federal Order No. 33, which is a grade and size regulation. The experience of two agreements providing for regulation of weekly shipment had convinced Federal authorities that conditions in the industry were not conducive to a volume regulation. Because many growers will not enter into an agreement with marketing firms to handle their crop before the season opens there is no way of making allotments on the basis of current control. Federal authorities have, I believe, held to the opinion that there has not been an equitable method of making allotments, except on the basis of current control. It is of interest that Order No. 33 dropped both weekly volume regulation and auction prorate, leaving only grade and size regulations. However, in 1946 the order was amended to provide for shipping holidays during the period December 20 to January 20. But no more than two holiday regulation periods may be instituted in a season and then for not more than a total of fourteen days. By this amendment a step back to the regulation of volume was taken, although it was rather minor. The shipping

holiday is of questionable value. If the trade anticipates a holiday regulation, they are likely to buy enough supplies to carry them through the holiday.

Since the order became effective, a period of little over 10 years, there has been 168 orange, 159 temple orange, 114 grapefruit and 84 tangerine grade and size regulations instituted. In addition, there have been four or five periods when all shipments of certain varieties were prohibited.

Regulations have varied in length from a few days to several weeks and have averaged about two weeks. Some regulations have been very restrictive prohibiting perhaps for some marketing periods 25 to 40 percent of the fruit harvested from moving to the market. Other regulations have restricted only a very small percent of the crop from moving.

The order is administered by eight growers, composing the Growers' Administrative Committee and eight shippers, composing the Shippers' Advisory Committee. Members of these committees are nominated by the industry and appointed by the Secretary.

Benefits of the Program

One of the objectives of the program has been to maintain a uniform high grade of product on the fresh market. It is the general opinion of the industry, in which I concur, that considerable has been accomplished in this field. Certainly some low grade fruit has been kept off the fresh market and diverted to the processed market. It does not follow that the processed product has been hurt as a result of this, because citrus fruits which are considered poor quality for the fresh market may be very good quality for processing purposes. A second benefit of the agreement has been that of excluding any grade or size fruit when the committee believed it would return red ink to growers. This relieves to some extent the burden of marketing cost placed on good grade fruit by tie-in sales when poor grades return red ink. Because growers object to close grading, which increases the cull pile, and because of the necessity of obtaining large volume for economic operations, any account sale handler is apt, perhaps unconsciously, to resort to the practice of tie-in sales.

Another benefit is the development of statistics which the industry needs in its operations. Statistics obtained for developing its marketing agreement policy are the only authentic data available

which indicates the quality of the crop at the beginning of the season. Throughout the season data are compiled by weeks which show prices by sizes and grades.

An important benefit of the program is the bringing together from time to time representatives of growers and shippers to study the marketing problems of the industry. These committees have gained considerable prestige which make them important factors in steering the industry along practical lines. This benefit is more far reaching than the interchange of ideas between the two committees and their alternates. Anyone in the industry may be heard while the committee is in session, or, as often is the case, industry people express their views to their committee representative before action is taken. Perhaps the greatest educational value comes from the contact of industry people with their committee representative. Here committee members pass on to the laymen the thinking and reasoning of the committee. When education is tied to price or profit as is the case here, it speeds up the learning process.

The benefit from the study of industry marketing problems is of course centered in the formulation of a marketing policy to be followed during the season. In some cases committee members are inclined to leave too much of this to the manager. The members should devote more of their own time in developing this marketing policy. In addition to the marketing policy formulated at the beginning of the season, marketing problems must be continually studied in light of ever changing conditions before recommendation for regulations are made. This necessarily requires a study of past regulations and an appraisal of the current regulations. A desirable feature of the Florida agreement is that regulations are subject to change upon the recommendation of the committees.

Changing Conditions in the Industry

Three marked changes have taken place in the citrus industry since the order regulating Florida citrus was instituted in 1939. First, Florida grapefruit production has doubled and orange production has more than doubled. Second, there has been a large increase in the percent of the orange crop processed. In 1939-40 season, only 13 percent of the oranges were processed, in 1947-48 season 50 percent were processed. It is believed that two-thirds to three-fourths of the crop may soon be processed. Apparently there will be frozen concentrate capacity in the state to handle 20,000,000

boxes of oranges, or one-third of the crop this year. Cannery capacity is enough to easily handle a third of the crop. This change in the form in which fruit is being marketed is particularly significant since the present marketing agreement does not cover processors. Should 75 or 80 percent of the fruit go to market in processed form it may reverse the customary packing house operation. It is possible that with 75 percent of the fruit going to the processed market the fruit for the fresh market will be sorted out from the processed fruit at the processing plant. The third condition is the rapid rise and decline of the Texas industry, which may be temporary, and the failure of the California industry to hold the dominant place which it held for over 50 years.

Agreement Still Effective

It is usually assumed that the most effective regulations under Order 33 are those covering tangerines. The reason for this assumption is that Florida has no competitors in tangerines and any restriction of undesirable grades or sizes on the part of the Florida industry will not be replaced by additional supplies of low grades and poor sizes from other areas. In addition, a small percent of the tangerines are processed, hence those tangerines restricted by regulation do not later appear on the market in processed form to compete with the fresh product. While these two things are true this should not necessarily mean that benefit from orange or grapefruit regulation may not be fully as profitable as tangerines. Where regulations are highly restrictive as when a large part of the product is diverted to processed form, it makes possible confining to the fresh market only the high quality part of the crop. This should aid in making advertising more effective and simplify the marketing operation because handling many grades and sizes is expensive and may be confusing to consumers. The process does not go so far as to not allow consumers a choice. Where a regulation is carried to this point, a part of the fresh market may be lost. Actually, before we can know that our regulations are on firm ground, additional research is needed in the over-all field of demand, particularly at the retail level.

It has been suggested that in addition to regulations the program serves a useful purpose in that it supplies a great deal of useful statistical data and is a basis of stimulating study by industry people of their marketing problems.

The Florida citrus industry, in general, is decidedly of the opinion that the present program is serving a useful purpose through its grade and size regulations, but, at the same time, it is convinced that the program is not adequate. Certainly a sizeable part of the industry believes that weekly volume regulations, with proration to auction markets, are desirable. A considerable segment of the industry believes that processors also should be controlled, although, it is difficult to advance a good reason for controlling processors where only grade and sizes are regulated. Those who advocate bringing the processor under the program are usually thinking of a program that would provide for allotments of oranges to certain uses such as fresh use, processed use, and possibly for cow feed. But with the rapid changes taking place in the processing field this would be a mistake.

If a method could be developed for maintaining equity between handlers with volume regulation it would be almost universally accepted. Notwithstanding the failures of volume regulation in the past, once without government participation, and twice with government participation, the citrus industry, for over a year, has been perfecting an organization (Florida Citrus Mutual) under which it hopes to achieve, among other things, volume regulation.

According to a press report of July 23, 1949, Florida Citrus Mutual intends to institute a program of volume regulations as well as some other activities which if not identical with the activities of the old Clearing House are very similar to them. The program for the 1949-50 season as announced by the board of directors is:

1. "Establish minimum prices for fruit utilized by canning and concentrate plants.
2. "Regulation of volume of fresh fruit shipments, with weekly allotments to shippers on a past performance basis, adjusted as crop conditions may warrant.
3. "Establishment of minimum price on F.O.B. sales of fresh fruit whenever such minimum prices are necessary to stabilize marketing conditions and to achieve a more orderly distribution.
4. "Allotment of fresh fruit shipments to metropolitan areas, whenever such allotment becomes necessary with allotments to shipper, recognizing their historical position in such markets."

Florida Citrus Mutual is reported to have 80 percent of the fruit under contract for 1949-50 season.

Among the directors of Florida Citrus Mutual are people who

have served on the administrative committees of Order 33 and others who were closely affiliated with the activities of the Florida Citrus Growers' Clearing House Association. At least some of these directors are aware that the week-to-week shipments of Florida oranges over a period of years have not deviated from the average any more than the weekly shipments have from California. In the face of all the evidence about volume regulation and the experience of the past, the Florida citrus industry believes that something should be done about controlling the industry in addition to grade and size regulation.

The activities of the Florida Citrus Growers' Clearing House Association and the plans of Florida Citrus Mutual have been injected in this discussion to show the interest the industry has in industry programs. Most industry people feel that certain controls are necessary. They would prefer to have these controls without government participation, but most commodity controls are ineffective unless there is complete industry concurrence, rarely achieved without government participation.

Industry people are also inclined to rely on a governmental program or programs to cure all their ills. The biggest problem that an individual grower or individual firm has is meeting the competition of his neighbors. Likewise the biggest problem that one segment of an industry has is the meeting of the competition of other areas. Government programs should not attempt, through subsidy or otherwise, to eliminate this competitive element in our economy.

MAINE POTATO MARKETING AGREEMENT AND ORDER

CHARLES S. MERCHANT
University of Maine

THE Maine Agreement No. 108 and Order No. 87 became effective November 15, 1948 and continued until June 30, 1949. Establishment of the agreement and order followed the usual procedure outlined by the Secretary of Agriculture. The program in Maine covered the entire state rather than any area or areas of concentrated production of potatoes. Over 90 percent of the handlers of this commodity voted for its adoption.

Specifically the marketing agreement and order stated that no handler of potatoes could ship any table stock potatoes of a variety or varieties of potatoes other than the Bliss Triumph variety, unless such potatoes met the requirements of U.S. No. 1 or better grade, and were not less than $2\frac{1}{4}$ inches nor more than 4 inches in diameter. The foregoing limitations on shipments of Maine table stock potatoes were not applicable to shipments of potatoes for export, or shipments in connection with government price support programs.

The order was administered by a committee of eight members, consisting of five producers and three shippers or handlers of potatoes. An equal number of alternate members were selected and served when regular members could not attend. The members and alternates were selected to represent each important potato production area in the state. The term of office of each member and alternate was one year. The duties of this committee were to serve as intermediary between the Secretary of Agriculture and any producer or handler of potatoes in carrying out the marketing agreement and order. Assessments were made against all rail and truck shipments to defray the expense of carrying out this program. All assessments above actual expenditures were refunded or credited on a prorata basis to all handlers. This meant keeping separate assessment accounts for nearly 2,000 handlers of potatoes.

The program in Maine started with very little opposition. There were only seven handlers who took active opposition to the program, some of whom were also growers. In mid-marketing season, about February, all the handlers had withdrawn their respective

petitions and requested dismissal of their cases. Thus the program was received and carried out with little opposition.

One year's experience with the potato marketing agreement and order in Maine is insufficient to draw definite and final conclusions. However, the past season's experience furnishes some indication of the desirable and undesirable features of such a program.

Desirable Features

The primary objective of this program was to supply the markets with potatoes of good quality and size. The size restriction for potatoes is considered a very desirable feature of last year's marketing program. However, more information is needed, both as to what sizes of potatoes consumers will buy at various prices, under various economic conditions when given a choice of purchase, and also the relative proportion of the potato crop falling within various size ranges over a period of years.¹

Also, it may be considered an advantage to the industry if the potatoes shipped to the market are of U.S. No. 1 grade or better. In recent studies of potato quality, the Maine Station² has found potatoes with grade defects in several markets far in excess of the tolerances allowed for U.S. No. 1 grade. Thus, a marketing agreement and order might help improve the quality of potatoes on the markets. However, to accomplish this requires careful grading and inspection of all potatoes. It automatically makes these two operations compulsory on the part of the handler. The compulsory phase may be considered a desirable or an undesirable feature.

Another advantage which is perhaps a complement to shipping only U.S. No. 1 quality or better is to encourage the consumption of more potatoes.

The shipment of only U.S. No. 1 quality potatoes or better with a somewhat narrower size range theoretically should encourage better handling of potatoes through the various marketing channels. Also, with a more uniform product of somewhat better quality the handling charges from the shipping areas to consumers should be slightly less, due to smaller losses and possibly to some increase in volume of sales.

¹ Merchant, Charles H. *Consumers' Acceptance of Sized Potatoes*, Me. Agr. Exp. Sta. Bul. 465, December 1948.

² Merchant, Charles H. and Woodward, Homer C. *Quality of Potatoes in Retail Stores in Boston, Mass. and Maine Markets, 1948*, Me. Agr. Exp. Sta. Bul. 466, February 1949.

Undesirable Features of the Marketing Agreement and Order

As commonly known, there is considerable range in the quality of potatoes which can be certified as U.S. No. 1. Under the marketing agreement and order it is often to the financial advantage of a grower or shipper to crowd the tolerance permitted under U.S. No. 1 standards. This is especially significant where the price differential is large between U.S. No. 1 potatoes and those of lower grades. This represents a real problem in grades and shipping-point inspection work. When shippers are crowding the tolerances allowed under U.S. No. 1 they are also encouraging lenient shipping-point inspection. Both of these are undesirable.

Closely associated with the quality problem is that of the cost involved in the grading and shipping-point inspection of potatoes. Inspection costs is an added expense to nearly all shippers, as normally inspection is not called for on all shipments. This additional cost to many central and southern Maine producers was rather burdensome where they marketed small quantities at a time in nearby markets.

For a marketing agreement and order to be successful satisfactory market outlets must be available for grades of potatoes not coming under the order. Unless the returns for the grades not permitted under the order are in line with U.S. No. 1 quality, growers and shippers are going to crowd the tolerances on all potatoes sold under the marketing agreement. In an area like central and southern Maine there are inadequate outlets for these poorer grades of potatoes. In these sections there were many more violations in proportion to the volume of potatoes handled than in the concentrated production area of Aroostook County.

Another disadvantage associated with the marketing agreement and order is that the consumer is left out of the picture entirely. Little or no attempt is made to find out what qualities are most desired. Some consumers have a preference for good quality, small size tubers. If they are unable to purchase the quality preferred they may reduce their consumption of potatoes.

Truck shipments of potatoes make the control problem much more difficult.

Under the provisions of the marketing agreement and order, certain exemptions can be made. Care must be taken that these exemptions do not become the rule, and the marketing order no longer function. This is an administrative problem requiring unusual skill for successful operation under certain conditions.

ELEMENTARY ECONOMIC THEORY OF MARKETING CONTROL

GEORGE L. MEEREN
University of California

THE major objective of this paper is to determine the degree to which available theoretical concepts are used as a basis for control policy. Most administrative committees operating under the Agricultural Marketing Agreement Act of 1937 seem to be seeking maximization of long-run returns to growers. They appear to be motivated by a complex of goals. They are not free of many of the legal or other institutional constraints inhibiting the degree to which income can be maximized or the methods which may be used by private firms. Committees know that to maximize money returns in any outlet will often lower possible maxima in other outlets or times; that heavy plantings may be induced; that the enabling statute prescribes a maximum of parity prices; and that where profit-maximization prices—which to individual firms stand as marginal revenue with respect to output—greatly exceed the marginal costs of shipping at allotted volumes, there will be universal and powerful temptation to overship allotments or to move prohibited grades, sizes, maturities or packs by individual shippers still conscious of individual competitive identities. The goals of administrative committees appear to be no different from those governing policies of non-agricultural agencies large enough to manipulate one or more profit determinants in addition to their own costs of production. To formulate shipping policy or to use theory there must be a routine in the relations among long-run profit determinants, sufficiently simple to serve as the basis for regular and systematic manipulation of one or more profit-determinants.

Net income to participating shippers could conceivably be increased through lowering costs of production or through monopsonistic pressures on prices of resources used. Joint action in production processes is not authorized. Factor costs are rarely if ever manipulated. Market control in practice means the manipulation of selling prices or of demands. For effective operation, every market control agency must achieve sufficient power over one or a few determinants of selling price to change the industry into a single firm with respect to the controlled price determinants. Except for

indirect effects upon production and procurement activities, other price determinants are unaffected.

Administrative committees are typically faced with a variety of specific questions: how much should be sold in all outlets over the season; what methods of limitation should be used; how should shipping rights be allotted; how should sales be allocated over alternative outlets; what are the optimum proportions by grade, size, maturity or pack; what time distribution will contribute most to the long-run profit goal? There is another set of questions relevant to groups other than growers: how do various regulations affect the volume of business and operating margins for handlers in current and subsequent seasons; what happens to demand levels in other outlets or subsequent periods; what happens to volume of production of the regulated good in the regulated area or in competing areas; how is the output of competing goods affected; what happens to volume of consumption and the proportion of income required to command such consumption in total and by special classes if price discrimination is used? One test of the usefulness of theory is the degree to which methods for answering such questions are suggested.

Methods of Income Enhancement

Federal orders seek to increase incomes through manipulating total receipts and not by decreasing costs. They provide for adjustments to given demands and for manipulating demands through central control over timing, constituency or allocation of sales. Product variation, intended to decrease substitution elasticities and thus to protect against lowered prices of competing goods, can be achieved only through grade-size controls. No direct advertising or other measures intended to lift demand levels may be used. The economic theory of federal marketing control is thus much simpler than that of state programs which may authorize joint control over the production function, factor-costs and both product variation and demand manipulation in addition to the techniques used in federal agreements and orders.

To achieve price or demand control, shipping authority over all or a large part of industry output must be centralized in a single agency. This can be done by cooperative marketing, amalgamation, product differentiation by large handlers or by agreements and orders. Prices can be manipulated in many ways. Product differentiation may decrease substitution elasticities and the size of market.

Advertising may lift demand. Increased buying power will raise some demands. Weather clearly affects some prices. Volume, time and space distribution and freedom of wholesale receivers from fear of unexpected gluts will affect season average price. Allocations over alternative outlets will partly determine season average price and thereby season income for multiple-purpose products. Grade-size proportions affect level of demand as well as price. The net relations of these factors to price are often fairly well known.

Prices varying with unknown factors, unsystematically, without stability or with such uncontrollable variables as weather, buying power, output of competing goods and perhaps over-all quality cannot be manipulated by joint action of growers or handlers. But within broad limits, other factors can be so controlled and net income thereby enhanced. To use most of these devices, two conditions are necessary: all handlers must participate; violations must be prevented. The techniques for such control may be classified into three groups: limitation, where the supply sold in any outlet or time is less than that which would move where shippers operated atomistically; diversion, where proportions sold in alternative outlets are different from those which would result from atomistic sale; and demand manipulation, where levels of demand are raised or maintained by control over timing, grade-size composition, spatial distribution or pack. So long as there are depressions, irregular outputs per acre of the regulated or competing goods and irregularity in other determinants of seasonal demands, there will be seasons in which demand elasticity for produced supplies is very low at the field level for industries which are well adjusted to long-run demand prospects. Under these circumstances, only marketings and not production can be controlled. For effective marketing control, all firms must take part and the temptation to violate allotments must be restrained.¹

In a competitive industry, shipments will be continued until

¹ Limitation programs are not always confined to emergency years when demands fall or yields rise. Capital—or acreage—may have become too large in face of the long-run demand outlook. At best, limitation eases liquidation through bankruptcy and revaluation of assets or through tree or vine pulling. At worst, it prevents effectuation of these adjustments which alone touch the fundamental problem. It is always difficult to know when capital is redundant—as in 1929-1939 for many industries now prosperous and presently for industries which have lost regular export outlets. Should trees and vines be pulled, requiring years of gestation if demand again rises; or should such industries limit sales and maintain productive capacity in the hope that political differences and war wounds will be healed?

the expected average price at terminal falls to equality with realized average costs of harvesting, packing, shipping and marketing—or when field price falls to zero and there is no contribution to production or capital costs whatever. If—when demand falls or yields rise or even when an industry is just too large for its demand—sale of full production would reduce field returns to zero, there can be no successful or enduring limitation of marketing without full industry participation. With such full participation and with effective enforcement, field price may be raised by many methods towards but not to the monopoly equilibrium. Such control will always be unstable because price—which is effectively marginal revenue with respect to output for a concern still competitive in all of its production and procurement and in most of its selling activities—will always exceed the marginal cost of marketing at the quantity allotted to the individual. Thus the decisions of a control agency must have the full effect of law.

In the short run at least, limitation will always involve hostility of interest between growers and groups of handlers, processors or consumers.

Where only part of an industry participates in a program, limitation will always lift group returns but by less than were all handlers to participate. There will be two inducements to violate allotted shipping rights: realized price will exceed marginal shipping costs at allotted volumes for all individuals; outsiders will obtain a higher price as a result of limitation by participants and will also move a larger volume than they would without limitation.

The effects of limitation cannot be measured unequivocally and for many of them, economic theory does not indicate either the data which must be obtained or the calculations which must be made in order to obtain answers. Limitation effectively translates a competitive industry into a monopolistic firm with respect to a very few price determinants but leaves most selling and all production and procurement activities unaffected. Marketing cooperation also means that with respect to some cost and price determinants, all or part of an industry becomes a single firm. However, the industry formulates its own program and it is not effective unless large majorities favor effectuation. No limitation program can long endure if there is an unregulated minority willing to capitalize upon restraints by other shippers while remaining free of any obligation to limit sales. No complete monopoly is ever created by these

programs even in the few profit determinants which are controlled. There is no indication in the many years of operation of these programs that the competitive alacrity, self-respect or entrepreneurial independence of growers and handlers is diminished. In view of the proper applicability of limitation programs to emergency situations in well-adjusted industries and the checks inherent in their prolonged use, it is doubtful that resource distribution is much distorted from the competitive norms. If limitation programs are effectively used in the two problems for which they are designed, they will in fact tend to prevent the deviation from competitive norms which result from the physical attributes of production, the small scale of output and the organization of marketing in fruits and vegetables.

Limitation raises aggregate net income by raising sales price in ranges of inelastic demand and by saving cost outlays in marketing the quantities which would be moved in the absence of control. Such limitation is not immediately desirable from the standpoint of any other group. However, the scale of operation, the rigidity of marketing costs, the physical characteristics of production and the inability quickly to adjust output, the sudden and uncontrollable deviations both in demand and in output and the organization of markets differentiate the produce industries from other parts of the economy. Limitation will always reduce the amount of goods consumed and thereby will damage consumer interests, although total consumer expenditures may also fall and some income classes may be clearly benefited if limitation is associated with price discrimination. The maximum possible transfer of income from processors, handlers or consumers to growers, is as discussed above, not often attempted. These groups may be benefited over the long run if controls maintain productive acreage which is economically profitable in face of long run demands but which would be destroyed because growers acting alone could adjust neither marketing nor production as demand changed or as yields per acre varied in a series of several seasons. With uncertainty of future demand, short-run transfers of income which facilitate maintenance of capital plant may not be hostile to long-run public interest. While the bankruptcy process would benefit other groups in the short-run, such gains in the form of more and cheaper foods and raw products might be more than countered by the relief costs associated with general business failure. The major danger lies in the abuse of

limitation to prevent desirable contraction in industries which are too large. Further, exaction of maximum possible profit in any season may damage growers through depression of demand levels in subsequent seasons and by inducing increased plantings of the limited product and its competitors.

The major issue here is the alternative to limitation. If, without intervention, field price fell to zero and crops still lay unharvested, the costs of bankruptcy and relief would necessarily be incurred. Production control aimed at profit maximization would involve more stringent output control and higher prices with even greater transfers to growers than would limitation. Depending upon the support percentage and the level of parity, support prices could involve even more limitation and would unquestionably lead to production controls if prolonged. Compensatory payments with markets cleared would cost more to government than would price support whether with destruction, gift, diversion or storage. Such payments with storage may involve least cost to government and consumers if demand recovers fairly rapidly. Perishable crops with low demand elasticities cannot be stored effectively. Marketing agreements and orders will ordinarily mean less restriction of output and less cost to government than will production control or price-supports and compensatory payments when demand elasticity and demand levels are unusually low and support is calculated from a parity price based on years when demand was relatively high.

Diversion Programs

Where outlets are separable and leakage can be prevented, discriminatory pricing will yield higher returns to the group than would uniform monopoly pricing. Limitation in major outlets frequently requires control over other channels. Violations will be induced both by the fact that realized prices exceed marginal shipping costs and because price differentials induce handlers to buy low and sell high where such differentials exceed the cost of transfer between discriminated markets. Without central control, atomistic shipping patterns will lead to equalization of field prices in all outlets. No generalizations may be made with respect to effects upon consumers since different classes are involved.

In limitation and diversion programs for staple crops and in markets substantially meeting the independence assumption, static theory lays out clearly the data which must be obtained and the

principles which must be applied in order to benefit growers. It also specifies major dangers to growers and indicates the divergences of interest which may be expected. But neither here nor elsewhere are there theoretical techniques which effectively indicate the impact of such programs in welfare terms.

Interrelated Demands

Intra-seasonal programs are mainly intended to prevent glutting in one or a few outlets and its spread to other outlets. There are three main types of such controls: rate of flow where time periods are interrelated; grade and size limitation; and minimum standards of quality, maturity or pack.

Markets may be glutted because small-scale handlers who are distant from markets react simultaneously and alike in accelerating shipments in response to market opportunities, high holding costs or prospects of heavy shipments later in the season. But if all react similarly, expected prices may not be realized and actual field price may be reduced below zero. No order can eliminate the risk of demand changes over the transit period. Marketing orders eliminate the risk facing wholesale receivers that unforeseen acceleration of arrivals may occur. Price-falls at wholesale do not seem to accelerate retail purchasing until retail stocks are cleared. The effects of the glut may therefore cumulate over time. Few facts on such interrelations are available but the interest of the wholesaler in margin rather than price makes such occurrences consistent with efforts of producers and wholesalers each to protect against unforeseen changes in price or condition of products. Except to indicate that total sales may be increased and total receipts to growers may be enhanced without loss to receivers for whom a major risk is eliminated and with no loss to consumers who may obtain a more desirable pattern of purchases, theory does not indicate maximization adjustments or their effects in temporally interrelated markets. Actually, rate of flow control may be intended to reduce wholesale market risks and by reducing marketing costs, raise grower returns. Thus far, no facts are available to form hypotheses.

Grade and size limitations have two declared purposes. First, heavy sales of some grades or sizes may bring losses. Second, there is evidence that flooding of one or more grades and sizes may reduce the level of demand in substitute classes if differentials become unusually large. Again no theory sets out optimum distribution prescriptions where demands for various grades and sizes are re-

lated. It appears that no damage is done to other groups when growers maintain the value of aggregate output by controlling the grade-size constituency of the sales in related markets.

Minimum standards of grade, size, pack or maturity have much the same objective. In response to individual opportunity or compulsion, handlers may increase their own returns by selling low quality or poorly packed products. They may thereby lower the demand for all classes of the commodity. Again there are little data on the effects of sales of low grade, small size or poorly packed products upon demand for other packs or grades and sizes.

Summary

Administrative agencies in marketing agreements and order programs apparently seek a price and profit goal consistent with long-run stability of income. Relatively few techniques of control are authorized. Production and procurement efficiencies are not sought through federal market control. Only the amount, the grade or size, the time or place distribution and the minimum standards of shipments may be controlled. Useful theory should set out the conditions for maximization and provide means to assess the impact of various programs upon growers, handlers, processors and consumers. Federal programs are intended in the main to make possible a monopoly-like adjustment to demands or to manipulate demands by control of sales in related outlets. Individual firms therefore lose little of their competitive identity and may increase their incomes by differential skills or scale in producing, procuring supplies or factors, in differentiating their products, in sales promotion and in nearly all merchandising activities. Only one or a few price determinants are centrally manipulated. Programs involving limitation may be analyzed effectively in terms of available theory. Diversion programs involving price discrimination may also be handled effectively. Programs involving rate of flow control, grade-size or other related factors and minimum standards cannot be analyzed in terms of existing static theory. No useful theory of related demands is yet available. The facts of market organization and operation on which such theory could be based are not determined. Few control boards—or anybody else—could unequivocally predict the effects of manipulating any short-run price determinant in one market, in several independent markets and especially in interdependent markets.

THE DEVELOPMENT OF BASIC DATA UNDER THE RESEARCH AND MARKETING ACT

HAVEN C. R. STEWART
Washington State Statistician

AMONG all progressive and intelligent peoples of the earth, the quest for more and better information of all kinds goes forward year after year. This is as it should be, for "genus homo" still has a long road to travel to attain the perfection of complete knowledge and understanding of mankind, to reap the fruits and complete fulfillment of man's productive activities, and to find the answer or "reason why" for all things material or spiritual. From the earliest records of man on earth, there are several indications of the use and importance of basic data. The Mandarins of old China and the Pharaohs of Egypt recorded production of food, fibre, and livestock, and used these basic data in formulating plans for future agricultural development.

Among primitive people, however, the fight for survival was usually so important that hoarding of some food was about the only exercise given the grey matter of these pugnacious ancestors. During the colonization of our country very few records of crop acreage or production are found before the Revolution, and little desire on the part of farmers for state and national crop reports during the first third of the 18th century. Letters and reports from our earliest Presidents, principally Washington and Jefferson, indicated their belief in and use of basic data and other information concerning farming operations at Mount Vernon and Monticello. In 1839, Congress made the initial appropriation of \$1000 for distribution of seeds to farmers and for collection of agricultural statistics.

During the 110 years that followed, work on basic data and related information for farm products, although it has expanded remarkably, has not developed in proportion to the increases in population, wealth, and complexities of our national agriculture. There is still a material lack of the basic production and marketing data needed for many phases of the agricultural program, both on a state and national basis. The United States Department of Agriculture, through its Bureau of Agricultural Economics, has scientists and technicians who are fully capable of expanding coverage and leading the work of collecting basic data, but facilities have

been lacking for anything like the complete job these newer marketing studies and developments demand. Since World War II many marketing problems have been centered in specific regions, states, or counties. Demands for fundamental facts increase rapidly as unstable economic conditions threaten any local agricultural industry.

These facts were recognized by Congress in a general way when preparing and passing the Research and Marketing Act of 1946. Section 203 of Title II of this act states in part, "The Secretary of Agriculture is directed and authorized to collect, tabulate, and disseminate statistics on marketing agricultural products, including, but not restricted to statistics on market supplies, storage stocks, quantity, quality, and condition of such products in various positions in the marketing channel, utilization of such products, and shipments and unloads thereof." Section 204 states, "The Secretary of Agriculture is authorized to make available from such funds such sums as he may deem appropriate for allotment to State Departments of Agriculture, State bureaus and departments of markets, State agricultural experiment stations, and other appropriate State agencies for cooperative projects in marketing service and marketing research to effectuate the purposes of Title II of this Act."

The Act apparently provides both a mandate and an opportunity to agriculture to get its research and marketing machinery in better order. Initial response to provisions of the Act has necessarily been slow, as its enabling features have required testing and experience. Also, it has taken about three years for many state, federal, and independent agencies to fully understand RMA provisions and to set up matching funds so projects could be submitted for approval. In his discussion of a paper titled "State Frontiers in Agricultural Statistics" presented by Arnold P. Benson at the September 13, 1948, meeting of the American Farm Economics Association, R. K. Smith indicated that nine states had cooperative RMA projects in operation that were developing primary statistics and related basic data for fruits, vegetables, hogs, poultry, milk, grain storage, alfalfa dehydrating plants, and prices received by farmers. Mainly, emphasis on all of these has been placed on the development of data for areas smaller than the state, complete enumerations or sample surveys of acreage and tree numbers, monthly prices, and monthly marketings.

Today, cooperative RMA projects of this type have been widely

extended. Allotment of matching RMA Title II funds, for developing new basic information to improve marketing services, facilities, and outlets, are negotiated through the Production and Marketing Administration. The approved programs are carried out under cooperative agreement between that Administration and the State Departments of Agriculture, the State Bureau of Markets, or other appropriate state agency. Simplified procedures for PMA-RMA programs in states have encouraged many State Departments of Agriculture to begin work in developing much needed programs relating to marketing facilities, services, outlets, and information. A brief summary of the essential criteria or requirements in setting up an RMA basic data project may be of interest. These include:

- (1) An objective which promotes the welfare of agriculture within the purposes of the Act.
- (2) Cooperation of all agricultural agencies.
- (3) Formal cooperative agreements.
- (4) Appropriation of state matching funds.
- (5) Coordination of the project programs to avoid duplication of work at a district, state, regional, or national level.

As an example of an objective, consider the plight of filbert growers in Oregon and Washington. Because of large filbert stocks on hand, average prices received for filberts by growers of the two states dropped from \$551 per ton in 1945 to less than half that price in 1948. Producers appealed to Federal and State departments of Agriculture, and to their agricultural colleges for help in saving their industry. Interested agencies, including the Filbert Co-operative, met and outlined a first objective which was, briefly, to expand market information for filberts. The stumbling block to a reliable market information program proved to be the lack of important basic data of tree numbers by varieties and age groups. The most recent filbert variety survey was made by WPA in 1935 and 1936. No basic data exists that would indicate probable trend of production in the immediate years to come, or show to what extent tree removals have influenced bearing surface of filberts. As in most cases of a similar nature, basic data is the key that unlocks the door to a sound information program. Incidentally, a PMA-RMA sponsored project for filberts is now assured for both Oregon and Washington beginning in the next month or two. It will supply acreage, tree numbers by varieties and age groups, and production check data.

Cooperation of all agricultural agencies is essential in planning

any RMA project, whether it relates to market expansion, basic data, or technical assistance. Every Federal and state agency that is connected in any way with a proposed project program should be given an opportunity to cooperate fully by taking either an active or advisory part in the program.

Formal cooperative agreements are also an essential of each RMA project. There are the formal agreements between the Production and Marketing Administration and the state agencies concerned, and also the agreements and working arrangements among the interested agencies within the States. Fortunately a majority of the BAE field offices have long had joint Federal-State programs in operation under formal cooperative agreements, chiefly with State Departments of Agriculture, but in some cases with the State Agricultural College. Since RMA has made such a strong point of this type of cooperative work, there is inducement for other State Departments of Agriculture to sign formal cooperative agreements with BAE and other agencies carrying on RMA project programs. In those states in which formal BAE agreements have existed for several years there has been relatively little difficulty in securing sponsorship of much needed marketing research projects.

As previously indicated, one of the main reasons why RMA projects were slow in starting during 1947 and 1948 was that state agencies had made no provision for state funds for matching. Officials in charge of the administration of RMA look with considerable favor on marketing research or service projects for which state agencies are willing to bear half the expense. An appropriation by the state legislature is the best assurance to the Research and Marketing Administration that state agricultural agencies mean business. In some cases the State's contribution may be partly through technical assistance employed with state funds.

Perhaps the chief factor to be considered in developing an RMA project is that of coordination of agencies and integration of the program. Functions of the Departments of Agriculture, Experiment Stations and Extension Services should be clearly outlined to avoid duplication of work at county, district, state, regional, or national levels. The principal agricultural agencies in a State must work closely together if the marketing program of each is to be successful.

A few basic data projects are now in operation in the Pacific

Northwest Region, as well as state projects in Oregon and Washington, and several new proposals have been submitted. One of the earliest projects to be developed related to the soft wheat industry. For at least two decades, marketing of soft wheat produced in Oregon and Washington and northern Idaho has been a "problem child" of the entire wheat industry. Wheat producers there generally prefer to grow soft wheat to the hard varieties as the yield per acre is much higher. During the years when this country was at war, especially during World War II, production of soft wheat was considered as important as any other kind as it helped in the all-out drive to produce more food for domestic use and for our allies. At the close of the war, high production was still encouraged by government support prices, as it was necessary under the Marshall Plan to ship millions of bushels to starving people in foreign countries. About two years ago, however, it became obvious to leaders in the wheat industry and to many wheat growers that as soon as requirements under the Marshall Plan declined, the Pacific Northwest would be faced with a wheat marketing problem more difficult than ever before.

Credit should be given to E. J. Bell, Manager, and the Board of Directors of the Oregon Wheat Commission, for initiating a program directed toward solving the soft wheat marketing problem. Early in 1947 Mr. Bell and his organization began development of a Pacific Northwest wheat project. They realized the opportunities for assistance under the Research and Marketing Act and were desirous of matching funds to secure every possible help in solving wheat marketing problems for the Pacific Northwest states. It was apparent from the start that any project work performed in Oregon would be of no value unless similar work was carried on in Washington and northern Idaho, and there has never been any thought but that the project must embrace all three states.

At the earliest meetings with the Washington-Idaho Wheat League, large producer groups and the Washington, Oregon, and Idaho State Departments of Agriculture and colleges of agriculture, Mr. Bell's plans were generally approved. From the outset the co-operating agencies found a dearth of information needed for expansion of marketing services or developing new markets. Records were very incomplete regarding utilization and disposition of the Pacific Northwest wheat crop after it had left the grower's hands. In other words, basic data were required, historically for as many

years as could be recorded for coastwise boat shipments, rail shipments, and foreign exports—all these by destination; also, quantities of wheat used locally for milling into flour and feed, wheat utilized by feed mills, quantities of wheat sold or traded by farmers to farmers, and an accurate check of acreage and production of wheat by varieties. None of the basic data for these items were available at the time the project began. At the close of the fiscal year just past, results of work on the project indicate that the historical record on coastwise shipments and foreign exports of wheat has been almost completed. Records had been obtained from most of the larger wheat mills, and an enumerative survey of smaller feed mills was nearing completion. The project has been extended and broadened for the current fiscal year.

Wheat variety surveys are now under way. Plans are being made to check railroad waybills in Milwaukee, St. Paul, Omaha, and local points within the state to obtain historic data of rail shipments of wheat by destination.

From the original start made by Mr. Bell and his Associate Project Leaders, N. I. Nielsen, Agricultural Statistician of Oregon, and Professor Harrington of Washington State College, the program has expanded this year to cover work not only on basic data but also other marketing information and development of new market outlets. This was brought about by Sverre N. Omdahl, Director, Washington State Department of Agriculture, who made specific requests to the State Legislature and was provided with funds for matching purposes to aid in research and marketing problems of all Washington farm products, with special emphasis on wheat. After calling a meeting of leading wheat producers and interested agencies, Director Omdahl submitted project proposals to assist in carrying forward the original basic data project and also to provide a new project aimed at developing both domestic and foreign markets for wheat. The new project will be closely coordinated with all other programs relating to Pacific Northwest wheat.

Estimated total cost of the project for the first two years is \$35,000. To maintain the new basic data series currently will cost at least \$10,000 per year, and state agencies expect to carry on their full part of the program. The question uppermost in the minds of practical wheat men is whether this outlay of funds can be justified. Evidence is overwhelming that returns from the investment will be far above the cost. For example, basic data already indi-

cates lowered sales of wheat and flour in the southwestern states, and if soft wheat sales there can be stimulated to regain lost ground, sales of wheat and wheat products will gain about three million dollars. Paralleling the basic data survey of wheat is one on transportation and rail rates by other than government agencies. Should the request for a downward revision of freight rates result in only a general reduction of one cent per bushel for wheat, the savings to producers would equal one million dollars.

It would appear, therefore, that the Pacific Northwest basic data wheat project is both paying its way and paving the way to improvement and expansion of the marketing program.

A fruit project started a year ago in Washington under cooperative agreements of the State Department of Agriculture and BAE's Seattle office with PMA-RMA, has developed a series of apple prices by varieties and sizes for 1947 and 1948 crops using reported F. O. B. sales of nearly 30 million boxes of apples. Significance of this data is that it shows the varieties and sizes of apples that sell at premium prices, and those that fail to bring cost of production. Another phase of the project was a combination mail and enumerative survey of fruit trees and grapevines by varieties and age groups. Use of state horticultural inspectors to secure records from orchardists who failed to respond by mail, has not proved entirely feasible, but results for some counties have been excellent. A preliminary tabulation of growers' record cards indicates a large increase in acreage and tree numbers for many kinds of soft fruit, and indications of fruit tonnage increases in the next five years range up to 25 percent (for sweet cherries). Expansion of grape acreage provides the indication of potential production by 1954 of double the present production. Basic data on prices of apples and numbers of fruit trees and grapevines secured by this PMA-RMA project is an example of the type that brings immediate returns to farmers and fruit growers and their allied organizations. Similar projects are being successfully conducted in other States.

From a personal viewpoint, the extra administrative and technical work of carrying on RMA basic data projects in the state of Washington has been much heavier than first anticipated. This indicates the need for additional capable technicians in BAE field office staffs to carry on such work. Accordingly, my advice to agricultural statisticians about to embark on cooperative RMA basic data projects is to be certain of sufficient funds for another top

professional on the staff, in addition to the clerical workers usually supplied.

In conclusion, basic data and related agricultural statistics are now being developed through cooperative RMA projects that would not otherwise exist. Of all activities under the Research and Marketing Act which may be undertaken to further research or to improve the marketing of agricultural products, basic data projects will continue to develop the type of definite results that will be widely useful to all interests in guiding current and future production and marketing programs.

DISCUSSION

GEORGE A. SCOTT

California State Statistician

The Research and Marketing Act greatly broadens the opportunity for Federal and State agricultural agencies to assemble additional data about farm products, when these data are helpful to producers in working out more efficient marketing methods. With its country-wide network of field offices, the majority of which are jointly operated with state agencies, the Bureau of Agricultural Economics is in logical position to participate in this expansion of basic information, when the need for data dictates that such action is worth while and appropriate. Requests for new and detailed agricultural data pile up in the offices of the State Agricultural Statisticians testifying to the need for more and better information in this field. These requests originate mainly among state and federal agricultural workers, and in producer groups seeking solutions of their marketing problems.

My comments relate specifically to the topic as it applies to these state offices of Agricultural Estimates, Bureau of Agricultural Economics, where RMA project work may be carried on with cooperating state agencies. They are based largely on our two years' experience with RMA project work in the California office.

The California office began planning RMA projects in the winter of 1946-47, and proposed specific projects early in 1947. The State Legislature authorized and appropriated funds for RMA project work in the spring of 1947 for use during the 1947-48 fiscal year. About a year later we were allotted limited federal RMA funds and given the green light for RMA project work, under standard agreement with the Production and Marketing Administration. Thus, before July 1, 1948, only a small beginning was made on one project. State funds again were made available for the 1948-49 fiscal year, and by early July we had assurance of matching federal RMA funds. Two main projects were in operation throughout most of the last fiscal year. In addition, we completed a small special survey, and started another good-sized project. The total combined funds used by

Agricultural Estimates for RMA project work in the state during the last fiscal year amounted to \$88,000. On one of these projects the counties contributed additional direct assistance, amounting to approximately \$25,000.

One project supplemented and enlarged upon the annual fruit and nut acreage surveys carried on in the state, in which the acreage of these crops are recorded farm by farm, and are summarized by county, by age groups, by kinds, and by major varieties, and include records of pull-outs and new plantings. The second project was concerned with developing poultry statistics through sample interview surveys. The third was a survey of bush berries in the state. The fourth involves surveys of the progress of raisin harvest, and estimates of raisin production, for which most of the work will be done in August, September, and October of this year. All of these were begun with the intention of maintaining the series of data year by year, so far as they proved to be useful to producers in connection with their marketing programs.

These projects have produced useful statistical data. However, some of our experiences with them have not been altogether happy, resulting in some sobering reflections.

Most of our difficulties stemmed from the fact that the responsibility for practically all planning, administration, operations, tabulations, analysis and preparation of reports, fell upon regular staff members who already have overburdening demands upon their time. Thus, the RMA project work seriously interfered with the regular duties required of our staff. Moreover, under such conditions, full justice could not be done the new projects. You may well wonder why additional help was not employed. The answer is that it is not possible to find qualified people on short notice to step in and carry off these jobs; nor is it possible to attract or to employ capable men in positions that offer little assurance of tenure. We also grossly underestimated the amount of time required of professional staff members to carry out these RMA projects.

Many difficulties and delays were encountered in setting up details of operation for proposed expenditures, clearing schedules, hiring personnel under rigid state and federal Civil Service regulations, and related matters. In order to start an RMA project in our state, a proposed budget must be drawn up many months in advance, hoping that the State Legislature will approve, that the project will be approved in Washington, and that adequate matching funds will be made available. Thus, financial plans, and at least general work outlines, must frequently be developed a year or more ahead of actual operations. Detailed plans for the conduct of a project must be worked out well in advance, and must be frequently revised to conform with funds finally allocated for the work. Many of these irritating and time-consuming details could be taken in stride if the statisticians and their assistants had adequate time to devote to them.

We have also been requested to make special studies or surveys on short notice, after it is too late for such projects to be included in our scheduled program. Normally, little can be done about such requests because of expected time lapses in clearance and approval. However, we were fortunately able to respond to two of them, because general provision had been

made for such situations, and one of our projects could be expanded or contracted to meet such emergencies.

It seems proper to say here that many types of agricultural data have maximum value only when they appear in a continuing series. Thus, it seems that proposed development of basic statistics under RMA projects deserves careful advance planning, and reasonable assurance that useful series will be continued. The uncertainty of simultaneously obtaining both state and federal matching funds for such continuing work is a source of considerable worry.

I suggest that State Statisticians exercise due caution, before new RMA projects are undertaken, to plan the work carefully in all its stages well in advance, to see that provision of both state and federal funds will be fully adequate to do the job outlined, and to assure the employment and training of capable professional personnel to carry on the work. When state appropriations for such work are based upon forward budget requests, one can hardly expect to go through all the preparatory steps for a good-sized project in less than a year, and it may well take two years before everything is synchronized.

Perhaps BAE could make more effective contribution to the development of basic statistical data for use in RMA programs, if more direct allotments were made to BAE by RMA. Such an arrangement would make for greater flexibility in operations, and would result in increased efficiency and uniformity in performance and results, especially when several states are involved. Proposed RMA projects relating to the marketing problems peculiar to a single state or to only a few states may best be carried on with matching federal and state funds. But it is believed that the procedures for implementing these cooperative projects might be simplified without impairment of the controls that are necessary in accounting for the use of public funds.

THE MAILED INQUIRY AND METHODS OF INCREASING RETURNS

FLOYD K. REED

Colorado State Statistician

THE mailed inquiry has provided the major source of information on the nation's crops and livestock since Abraham Lincoln's Secretary of Agriculture first sent out inquiries during the Civil War days of 1863. Significantly, it was learned at that time that the country's food supply would be adequate to meet war needs. This method of obtaining up-to-date information regarding agricultural production, combined with inquisitive and observing field travel and contacts with individual farmers for certain types of information, has been the backbone of the country's crop and livestock forecasting and estimating program for more than three-fourths of a century. With this long record of achievement, it would seem that much can be said in its favor and little need be said in its defense. More recently through a succession of years in World War II and down to the present, as late as August 10, 1949, use of the mailed inquiry has proved its worth as a reliable source of information regarding production of the country's crops and livestock. The crop and livestock reports compiled from this type of information during World War II formed the basis for establishing a reliable food production and distribution program. As in 1863, but this time through six war years and subsequently, large crops were revealed by this source of information. Plans for effective use of our food supplies were and are predicated upon the reliability of data thus obtained. It seems now quite clear that when we were exporting large quantities of food to all parts of the world during these war years we could easily have exported ourselves into a condition of serious food shortage or even semi-starvation had these reports not been reliable.

Much is taken for granted when we use the mailed inquiry as a source of information. In the first place, the mailed inquiry makes use of the facilities of the Post Office Department, a far-flung and wholly reliable government agency, in lieu of setting up an expensive field organization for making the necessary contacts. It assumes a high degree of intelligence, education, and ability on the part of recipients. It is one of the best illustrations of the operation of our democratic process wherein producers of crops and livestock

cooperate with a government agency in their own and the public interest.

Other advantages of the mailed inquiry are its comparatively small cost, and the speed with which the information can be cleared, even in a country as large as the United States, through use of its extensive and swift transportation system. The mailed inquiry makes farmers or ranchers feel that they have a personal part in making the report for their own industries. One who cooperates in filling out a mailed inquiry and thoughtfully makes a record of his judgment and knowledge probably comes very near giving his real views regarding the condition of crops or agricultural developments in his locality. One who votes his convictions in the privacy of the voting booth might vote differently if someone were looking over his shoulder. A substitute for this type of mass judgment or "safety in numbers" factor in appraising the condition of crops or livestock would be extremely difficult if not impossible to devise. The use of this mass judgment factor has proved its worth many times. It is the foundation of the crop-forecasting system. The good judgment of many minds tends to give stability to the appraisal. Most judgment information has related to the condition of crops and livestock, but it has also been used to a limited extent in measuring the changes in crop acreage and in livestock numbers. In addition to judgment information, "sample" data concerning individual farm operations, such as crop acreages and livestock numbers, are obtained through use of the mailed inquiry. These form an essential part of the fact-finding program.

If we were to sum up the advantages of using the mailed inquiry, we might list *speed*, *economy*, and *reliability* as the three great virtues of this method of obtaining information regarding the country's great and diversified agricultural plant.

Problems and Difficulties in Securing Response

Even with the three great virtues of the mailed inquiry, the very title of this paper implies that difficulties are being experienced in obtaining adequate replies. This title might even imply that use of the mailed inquiry was on trial or was facing competition. Both inferences are at least partially correct.

A comparatively recent inquiry to BAE field offices brought many remarks about the difficulty of obtaining replies to mailed inquiries, but there was little comment about the cause of poor response. If we are to understand why we have problems of obtain-

ing a sufficient number of returns or a sufficient percentage of returns we must first understand why we are experiencing these difficulties. Let's think about these for a moment.

Subsequent to passage of the Homestead Act of 1862, particularly in the West, the United States Government was viewed by many as big-hearted, a government which gave every man 160 acres of land for the mere act of residing upon it and "proving up." The Government itself was a rather abstract or incidental sort of thing in the minds of many people. Many people weren't conscious of the Government touching their daily lives to any considerable extent other than through the Land Office. There may have been a strong feeling in those days that only good came from government, partisan political feelings may have been less intense, and views on social philosophy were perhaps less controversial. Income taxes were for the most part nonexistent. In those earlier years and well into the present century, when farmers and ranchers received crop or livestock inquiries from a government agency, they viewed it pretty much as an honor or a privilege to furnish information to a generous government. Because the economy of the country was less involved than it now is, these inquiries were shorter and came less frequently. With economic problems becoming more involved and the agricultural industry more highly developed, these inquiries have grown longer and the farmer receives them more frequently. Recently, in many cases, instead of feeling that he has been singled out as a person worthy to do his government a small service, he is inclined to look upon these inquiries as "just another of those things."

Only 15 years ago crop and livestock inquiries comprised the principal kind of franked or government mail received by most farmers and ranchers. In recent years they receive government mail from many sources and many of them give hours of their time to serving on government agency committees of various sorts. (Many also serve on county and state boards and committees not directly related to Federal government activity.) This leaves less time for filling out crop and livestock inquiries and many feel that in doing this type of committee work they are doing all the "useful citizen" work for which they have time. All these developments have increased the difficulties of obtaining adequate response to mailed inquiries, but their growth was *gradual* the first half of that 15-year period.

During World War II these aversions *increased rapidly*. Among

the causes were irritations resulting from price regulations and shortage of labor and material. During that comparatively short period income taxes came as a new experience to most farm and ranch people. Changes in farm ownership resulted in many old-timers who had been crop reporters for many years leaving the farm. In a goodly portion of cases they did not pass the crop-reporting responsibility to younger hands. Occasionally one meets an old-timer at agricultural meetings who points out that before retirement from the farm he was a crop reporter. One meets others who say, "I used to be a crop reporter but quit because of the pressure of other activities." Still others adhere to the old bugaboo, "I used to be a crop reporter but gave it up because I felt that it was only for use of speculators."

These general considerations, together with the *negative influence of much adverse criticism leveled at government* in recent years, have greatly reduced returns. This, together with the very presence and demanding activities of many public agencies, has done much to dry up the source of information so fruitfully available through use of the mailed inquiry. The agricultural statistics agency needs the help of all these agencies in informing farmers and ranchers of the need for these basic facts and in overcoming the negative attitude toward furnishing them.

If we are to increase both the actual number of returns to mailed inquiries as well as the percentage response, we must take steps to overcome these inherent difficulties.

In light of the above obstacles, it appears that the kind and form of the questionnaire may be secondary to the inherent willingness of the farmer or rancher to respond. The questionnaire itself involves the mechanics of the problem, but the willingness to respond can only be increased by a broad-scale and continuous educational process. It is in this field that other agencies working with agricultural groups can be most helpful.

Methods of Increasing Returns

Methods of increasing returns may be divided into three categories: (1) Appeal letters or letters of explanation; (2) the questionnaire itself together with the mechanics of distribution; and (3) education as to the need for making the report. The educational aspects need immediate as well as long-term and persistent atten-

tion. This paper does not deal with the mechanics of selecting the correspondents or the methods of insuring proper distribution of returns.

Appeal letters should be impersonal in an individual sense and free from reference to controversial subjects. Many people are public spirited, and an appeal to this aspect of citizenship or that the information is being obtained in the interests of the industry generally or the particular commodities which the individual produces may be effective. Emphasis on the fact that response is voluntary and that individual reports will be held in confidence has strong appeal. (The feeling on the part of many, however, that there is a relationship between reports and income-tax collections is difficult to overcome.) Pointing out that serving as a crop or livestock correspondent will increase the individual's power of observation and retention of information seems also to be effective. A little encouragement in the way of suggesting that the correspondent should not make too hard work of filling out the report is helpful, and statements like "report for your own farm and in addition just put down what you know about conditions from your day-to-day observation in your locality" are also helpful. If the recipient can be made to feel that it is in his interest to fill out the questionnaire, he will be more likely to respond. As one of our reporters put it, "A man ought to fill out those questionnaires for his own selfish interest if for no other reason." The old statement that "a man's judgment is no better than his information," followed by a reference to the effect that "working without agricultural facts is like working in the dark," appeals to the practical minds of rural people. It is almost a duty to point out that having accurate facts regarding agricultural supplies is as important in making a profit in agriculture in these times as is use of new varieties, adequate fertilizer, and control of insects and diseases. Pointing out this important fact is an essential part of the immediate, as well as the long-term, educational program. Mr. Creer of our Montana office has developed a short appeal letter which starts out, "Has someone been kidding you?" He then goes on briefly to shoot down the clay pigeons regarding the impression that facts concerning agricultural production are for the benefit of the speculator only. Some years ago the Colorado office developed an appeal letter which started out, "There's no use kidding," and then took the farmers and

ranchers into our confidence regarding the fact that returns were becoming inadequate for proper service to the industry. This met with fine response and did much to increase returns.

It isn't practicable in a paper of this sort to deal with all the ways of appealing to rural people for cooperating in returning mailed inquiries. Yet a few additional points should probably be mentioned. No effort should ever be made to make replies compulsory. My experience in studying the Japanese crop-reporting system revealed that, even in a country like Japan where requests were mostly orders, the agricultural statistics data had a pronounced downward bias resulting partly from this compulsion factor. The situation there, as in some of the war-torn European countries, was no doubt aggravated by the exacting food-collection system, but the principle of what happens under compulsion is well illustrated. Because of the rather serious nature of the business, anything of the "atta boy" or "let's die for dear old whozis" nature would probably have little appeal. It would be more likely to bring criticism. Likewise, an appeal of the sort that implies "this will be good for the crick in your back" will not bring results. The appeal must be sincere, informative, realistic, and to the point.

Coming now to item number two, the schedule itself should not be unduly long and it should have definitive application both locally and to the problem at hand. The question should be clear and the mailing data timely. No questionnaire should prompt a reaction like the cartoon which appeared during the mid-war years. The scene pictured a farmer and his wife sitting around the livingroom table in the evening. The wife had just opened a letter and was saying to her husband, "It's from the government, Pa. It's about that plow you ordered. They want to know what you're going to use it for."

The mechanics of obtaining responses are pretty much a separate consideration. One thing seems important—it should be readily possible for one who is willing to serve as correspondent easily to identify mail originating from the crop-reporting office. Use of window envelopes with the individual's name on the schedule has proved a stimulant in some cases. One of our offices sends out a simple "pre-survey" card reminding the folks that in about a week they will receive an important inquiry form and that it will be appreciated if they will fill out the inquiry and return it promptly. Placing of special words on the envelope or on the schedule, such

as "Urgent," "Answer Requested," "Please," "Special Crop Inquiry," etc., make their own special appeals. During the war the Colorado office stamped the outside of the envelope with "War Emergency Makes It Important That You Return This Inquiry Regarding Food." The immediate response to this appeal was tremendous. (Even using this stamp on inquiries going to broom-corn growers didn't seem to minimize its usefulness.) The significance of this particular phrase was that it had strong appeal because it was tied to an important cause. Others can be devised to meet current conditions, and although they may not have the strength of appeal the war had, at least they will make individuals feel a personal responsibility in giving a complete reply. Appeal to what is sometimes called "sweet economic reasonableness" is unlikely to be effective in dealing with rural folks.

We come now to item three which to me is the most important phase of this work and one that needs the most attention by the most people—the educational phase. The discussion so far should have made clear that a small organization like the present crop and livestock estimating organization cannot cope with the broad-scale need for education in this field. It is a job for many. Farmers and ranchers themselves are the main source of accurate information regarding crop and livestock production in its various phases. It would seem therefore that the matter of cooperating in a phase of work which has such an important bearing on agricultural problems should be emphasized in the educational system, including the rural schools. There should be a place for emphasizing the need for farmer assistance in this work in the vocational agricultural program, the college economics courses, and in the program of the Extension Service. It would seem to be as important that a farmer or rancher learn through his educational process about the part he can play in developing facts about his industry as it is that he know how to farm well or how to manage livestock intelligently. Personnel of government action agencies, who frequently hold meetings with groups of rural people, should emphasize this point. This might well be an important phase of the educational program of the Extension Service.

Officials and directors of commodity group organizations, such as potato, sugar beet, wool growers associations, should be requested to call the attention of their membership to the importance of returning the inquiries they receive, from which important economic

facts bearing on their commodity are developed. The importance of this action should be brought to the attention of leaders of the large farm organizations. We have worked with all these groups in Colorado with considerable success, but this matter needs to be frequently emphasized. The importance of returning these inquiries which are the fact-gatherers for the agricultural industry won't go across in one easy lesson. It must be emphasized by repetition, much like the Negro preacher who, when asked why he was so successful in getting many conversions, replied, "First I tells 'em what I'se gwine to tell 'em. Then I tells 'em. Then I tells 'em what I told 'em." So it is with the educational process of increasing mailed inquiry returns. It must be emphasized in spring, summer, fall, and winter. A principle of salesmanship is that you can sell a commodity if you can make the customer want it. Mailed inquiry returns can be increased by making the respondent *want* to fill out the inquiry or through making the reminder so pleasantly irritating as to insure a return for the sake of gaining a clear conscience.

Persons of all government agencies which contact farmers should say a good word for the mailed inquiry. Since all need the facts which these inquiries develop, all will benefit from the results. Good percentage response, in addition to making the data more authentic, will cut costs and cut wear and tear on brake linings of rural mail-carrier automobiles. There should be a joining of hands on the part of all groups that have an interest in and a need for these basic facts.

Careful thought should be given to current and future needs for factual information. Many times in the past there has been demand for historical data which, because they were not currently compiled, were gone forever. With this lapse of time any facts developed subsequently would of necessity have to be of the "crystal ball" nature.

In many respects a nickel's worth of statistical-gathering machinery is available to cope with a dollar's worth of problems which need reliable statistical and economic facts for intelligent solution. It would seem, therefore, that for the present at least the best alternative is to continue to make the mailed inquiry effective and to improve its results as much as possible. (Here again let me point out that some of the usefulness and advantages of the mailed inquiry could not be exceeded even with expenditures of large sums of money.) Recognizing the democratic principle embodied in use of the mailed inquiry to the voluntary reporter, and the assurance

of continued large rewards, the helping hand of all agencies should be extended in its support and improvement.

DISCUSSION

R. K. SMITH

Bureau of Agricultural Economics

More and more, efforts have been made to improve on the many phases of mailed sampling techniques. This has led to research in sampling by mailed inquiry along the following lines:

- (1) Design of questionnaires
- (2) Characteristics of respondents and factors affecting response
- (3) The use of controlled and semi-controlled mail sampling
- (4) Techniques involving repeated mailings and follow-ups

(1) *Design of questionnaires.* One of the principal faults of many questionnaires is that there is so much to ask and explain that the printing has to be extremely small to get it all on the schedule.

When the proposal to shift the Prices Received schedule to larger type was made, a method for testing response was set up in four mid-western states. One group received the old type schedule and the second the new which is set with larger sized type and in which much of the explanation appearing on the old type schedule has been eliminated. New respondents were also separated into two groups and sent the two types of schedules. So far the record of returns from the two questionnaires indicates no significant differences as to the rate of returns between the new and the old for either the regular reporters or for the tryouts.

Another experiment has been tried in Tennessee and Kansas involving the Prices Received questionnaire. This questionnaire is rather long; it contains about 50 questions on prices and goes each month to buyers of all kinds of farm products. Often a particular reporter handles only a few of the items covered. Four short separate questionnaires were designed, with the commodities grouped so that the respondent on a particular list would be handling most of the commodities on which prices were asked. The results have been carefully analyzed and in neither state does the "T test" indicate a significant difference between the prices reported on the regular schedule and those reported on the split schedule. The percentage of return from the split questionnaire was higher but in terms of total number of price quotations per questionnaire mailed the regular inquiry was more efficient. Generally, it resulted in a larger number of price quotations for a particular item than did the short schedule.

It has been found that often leading questions relating to some general item or items will have pulling power and will encourage returns from reporters who have few or none of the items being sampled. For a long time many of the special surveys used by Agricultural Estimates have carried questions of a general nature, primarily for their pulling power. Obtaining reports from the so-called "zero" reporter is of utmost importance in mailed sampling.

"Fatigue" in reporting has been generally accepted as a major influence in response, both on mailed and interview surveys. Some recent explorations into this field reveal that response is not always closely correlated with length of questionnaire. It is evident that the "interest" factor is a major influence in offsetting fatigue.

Tests on the effect of using airmail for sending and returning schedules showed a significant difference in the rate of response when airmail was used. The gain in one instance when airmail was used both out and back was as much as 30 percent.

Back in 1940 Illinois tabulated 26 percent of the number of questionnaires mailed for an August cattle on feed survey. That inquiry contained only five questions; it was mailed to a developed list of reporters. Contrast this with the returns of 72 percent from the July 1, 1949 cattle on feed questionnaire in Illinois which contained 32 items. We need more research into response on questionnaires that yield a high return.

(2) *Characteristics of respondents and factors affecting response.* A number of studies have been made on differential response to mailed inquiries, especially in connection with controlled and semi-controlled mailed sampling. Analysis made of the returns from a controlled mail survey on livestock showed significant differences in response, with farms having large numbers of cattle more likely to reply than those having small numbers. For hogs, however, farm operators with large numbers were less likely to respond. On this same survey it was found that response varied according to age of the operator, with the middle age groups showing the highest rate of response. A mailed survey in January 1948, on livestock, grain stocks, and tractors revealed a tendency for "farms with no tractors" to respond. In delving more deeply into the problem of response, more work needs to be done on studies where social and economic status of the reporter is associated with response.

(3) *The use of controlled and semi-controlled mail sampling.* Various interview surveys made in January 1947 and in April and September 1948, provided the basis for controlled mailed sampling for five surveys dealing with electricity, livestock, grain stocks, tractors and meat curing. In some of these surveys returns from mail inquiries so closely represented the parent sample on certain check or control items that no special adjustments for differential response were needed. For other items the response was selective and adjustments were needed.

In semi-controlled mailed sampling, certain data, which have a high correlation with the item or items to be estimated, are abstracted from the State Farm Census or other major surveys, for each prospective respondent who is to receive a mailed inquiry. It is possible, therefore, to determine beforehand how well the sample reflects the universe by comparing averages of the control items for the sample, with averages for the same items from the State Farm Census or other major survey from which the sample was drawn.

Our experience in using this method has been exceptionally good. Analysis of the control data for the mailed returns supports the general belief that crop reporters are a selective group.

(4) *Techniques involving repeated mailings and follow-ups.* Studies have been conducted to determine the effects of repeated mailing and follow-up techniques on sample averages. The Wyoming Livestock Loss Survey discussed by Mr. Knutson showed that the sample of nonrespondents had smaller losses on the average than those who replied. In general, the first wave of returns from a survey on a specific item tends to include reports from individuals who have something to report and who are most interested in the subject. Those with small numbers, or those having none, are inclined not to send back the questionnaire. Repeated mailings or follow-ups encourage a response from those who failed to return the first questionnaire received. In some cases each follow-up return progressively yields a smaller average, thus tending to lower the average for the entire survey.

Data from repeated mailings tabulated separately for the purpose of studying response show that in many cases the percentage response to a second request is as large or larger than from the first mailing.

There is a study on use of special envelopes that is just starting which will be of interest to this group. Mr. McCandliss of our Mississippi office has designed a special, distinctively marked outgoing and return envelope to be used for our General crop surveys. With the permission of the Post Office Department the effect of these envelopes will be tested in five states during the next few months. It is hoped that the envelopes will (1) increase the total response and (2) cause replies to be returned more promptly. Both of these hypotheses are to be tested.

Conclusions

There are other illustrations of new developments in mailed sampling which have not been mentioned. Some studies and sampling schemes have been covered only briefly and others omitted because they closely resembled those presented.

In reviewing the progress one might conclude that great strides have been made in the field of mail sampling. But the surface has been barely scratched. It is folly to conclude that the results of a set of experiments derived from one survey or on one subject apply equally well to other surveys or other subjects. Each of the surveys, each of the subjects, each of the commodities have their individual problems in response, in sampling methods, and in treatment of data. These problems need to be solved by a process of continuous investigation along all lines.

These new approaches in mail sampling, however, point up the importance of "follow-up" practices. They show advantages to be gained by systematic repeat mailings and separate tabulations. Not much has been done on follow-up interviews of nonrespondents to mailed inquiries such as was done in the Wyoming Livestock Loss Survey.

Experiments show that there are ways to improve response to the mailed inquiry. Dwindling returns should be not the inevitable consequences of mail sampling. New schemes need to be tried and newer ideas developed. More than that, tests must be continued to find the factors associated with response and the best design for mail questionnaires.

WINTER STORM LIVESTOCK LOSS SURVEYS IN WYOMING

GEORGE KNUTSON
Wyoming State Statistician

THE Western States were besieged by storms and subnormal weather during the months of December 1948, January and February and until mid-March of 1949. Wyoming experienced its worst storm on record during the period of January 2, 3 and 4. During this storm, wind velocities reached 68 miles per hour, temperatures dropped to eight below zero, coupled with snow. Highways, byways, and railroads became blocked with snow drifts varying in depth from a couple of feet to as much as 15 feet.

Another storm, of somewhat lessened intensity, occurred in February in the Red Desert Area, embracing Carbon, Sweetwater, and Natrona Counties. During this storm wind velocities attained a maximum speed of 75 miles per hour. Temperatures were below zero and snow fell during the storm. The highways and railroads were blocked for an 11-day period because of ground blizzards.

The first blizzard encompassed a very wide area in the eastern part of this state. Eleven of the 23 counties of the state became snow-bound. There appeared to be two vortices in this storm. One centered around Cheyenne, and the other at Van Tassel, which is close to the northwest corner of Nebraska.

Shortly after the storm broke it became manifest that there would be a severe loss to livestock and wild game on the plains. Some animals froze to death, others were smothered by ice closing the nostrils, appendages were frozen, which in some cases made it necessary to destroy the animals. The economic loss to breeding animals was believed to be great and mounting daily. Unofficial estimates of losses took on huge proportions. Some unofficial estimates of the number which perished in the blizzard were as high as 50 percent of the cattle and 75 percent of the sheep. Our office was besieged by the press, stockmen, lending agencies, and others who wanted information on death losses. The wild rumors of losses suffered was giving the state considerable adverse publicity. As time went on the pressure for exact information as to the death losses became increasingly great.

The Bureau of Agricultural Economics is charged with the responsibility of collecting and publishing significant statistics of the

livestock industry. These statistics not only include estimates of the number of livestock on farms and ranches at any given time but also many other factors that influence the livestock population. Estimates of death losses to livestock and other storm damage affecting livestock fall into this category.

Frequently the residual effects as shown by subsequent poor condition of breeding animals, forced marketing due to injuries, and reductions in the calf and lamb crops are of far greater importance than the immediate death losses due to the weather phenomena. However, the great variation in the publicity as it affected the livestock industry required that an early survey of losses be undertaken.

During December the comprehensive annual Rural Carrier Survey of livestock on farms is completed. This survey is the basis for the official Department estimates of the livestock population as of January 1. Completed questionnaires are received from many hundreds of farmers and ranchers—reporting their own livestock numbers. It was decided that a short concise storm loss questionnaire would be mailed directly to each of those operators located in the storm area who responded in the Rural Carrier Livestock Survey. The primary purpose of the survey was to obtain a rough estimate of the level of losses in order that any contemplated action programs could be planned with a reasonable degree of accuracy. As only about three weeks had elapsed between the January 1, livestock population estimates and the date of the storm loss questionnaire, it was felt that memory bias would not be a significant factor.

The storm loss questionnaire was extremely simple in that the respondent was asked to report: (a) the number of all sheep and lambs he had as of January 1, (b) the number that had died due to the storms during the month and (c) the number of additional losses he expected to have because of the storm. In the case of cattle the same three questions were asked but, in addition, the respondent was asked three additional questions about his 1948 calves. This latter separation was made because of persistent reports that yearlings and other young cattle had suffered more extensively than older stock.

The questionnaire was mailed during the period January 24-28 and the survey closed on February 7. The computed percentage death loss was then applied to the January 1 population of cattle

and sheep to produce an estimate of the actual loss in terms of number of head. The loss survey results were published in an official release by the Department of Agriculture on February 10, 1949. The significant data by states are as follows:

TABLE 1. LIVESTOCK STORM LOSSES UP TO FEBRUARY 1

State	Cattle		Stock Sheep ¹	
	Percent Lost	Head Lost	Percent Lost	Head Lost
South Dakota	1.6	16,000	2.5	13,000
Nebraska	2.6	46,000	7.0	23,000
Wyoming	3.0	16,000	4.8	49,000
Colorado	.8	3,000	.5	2,000
Total Storm Area	2.0	81,000	5.8	87,000 ²

¹ Excludes sheep and lambs on feed

² An additional 10,000 head was estimated to have been lost in the fringe storm areas and in feed lots.

The foregoing summary of storm damage did not mark the end of the winter livestock losses in these western states. During the month of February additional storms harassed the area and were particularly severe in the south central and southwestern counties of Wyoming. This area comprises in part the very important winter sheep range known as the "Red Desert."

In the early part of April funds were made available for a comprehensive livestock loss survey in Wyoming. This state was selected because of its nearness to the center of the storm area and because of a demand from Wyoming farmers, ranchers, and state officials for a final comprehensive appraisal of the winter storm damage to the livestock industry. Reports were again persistent that sheep losses during February had been very severe and that the calf and lamb crops would be greatly reduced.

My office is fortunate in that it has available a nearly complete list of names and addresses of farmers and ranchers in the state. The second livestock loss survey sample was designed as a combination mail and non-response interview procedure. The mailing procedure required that one mailed follow-up be sent to each farm or ranch operator who failed to respond to the original questionnaire. The follow-up questionnaire was accompanied by a letter soliciting a response. After the returns from the follow-up questionnaire were collected a sample of non-respondents were selected for personal interview. The original mail sample was drawn at random and stratified by counties proportional to the number of livestock farms

in the county. The area to be surveyed under this procedure included 14 eastern and central counties of the state. In addition a somewhat smaller mailed sample was allocated to the remaining non-storm counties. This latter procedure was included to permit comparisons of losses in storm versus non-storm counties and to permit inclusion of statements concerning the entire state in the report of winter livestock losses.

Past experience tells us that the winter and spring livestock loss in Wyoming seldom exceeded about two percent of the cattle and six percent of the sheep on farms and ranches January 1. Thus with such relatively small figures, it was desired to design a sample to yield a percentage loss estimate with a standard error of 0.5 percent. The standard error from a random sample of n farms is given by

$$(a) \quad S\bar{x}^2 (= s)^2 \left(\frac{1}{n} - \frac{1}{N} \right)$$

in which s = an estimate of the standard deviation of the individual farm death loss percentages and N = the number of farms in the universe. It was estimated the standard deviation would be 15 percent. Thus

$$(b) \quad (15)^2 \frac{1}{n} - \frac{1}{7,300} = .25$$

The desired sample size was computed to be approximately 900 farms or ranches.

In order to assure that the mailed response would reach the desired 900 farms and ranches a stratified random list of approximately 4,000 names was drawn in the 14 counties. In addition a stratified random list of approximately 2,000 names was drawn in the non-storm counties.

In the planning stages it was decided that the non-response interviews should be taken at the rate of about 10 per county allocated finally on the basis of the percent non-response and total number of farms by counties. As the survey developed, the amount of available funds and shortage of operational time would not permit the interview of the desired 140 non-respondents. The great distances between ranches required that the number of non-response interviews be limited to a maximum of 125.

The non-response interviews were allocated by making the number of such interviews proportional to the product Px , where P

is equal to the percentage of Census farms in the County, and x is equal to the percentage non-response. On this basis the minimum number of non-response interviews allocated to any county was five and the maximum 20.

Because of time limitations the program of field operations was very rigid. The loss questionnaire was first mailed out on May 9-10, with the follow-up circularized on May 18-19. The non-response interviewing started May 31 and ended June 4. This very short period did not allow full benefit from the follow-up mailing. However, the return from the mailed questionnaire was believed to be fully satisfactory although it did not quite reach the optimum number of 900 reports. On June 4 slightly less than 800 returns had been received. Late questionnaires received after the closing date for the survey have increased the return very close to the computed sample size. The non-response interview sample had about the same degree of incompleteness as the mailed sample. A total of 89 interviews were secured in five days—a period in which field work was seriously hindered by constant rainy weather. In a number of instances non-respondent farms could not be reached because of washed out roads. Without a definite procedure for repeated visits to locate absent respondents, it is doubtful that the non-response interviews would have exceeded 100 even with most favorable interviewing conditions.

Of necessity, the questionnaire used was rather complex and lengthy, considering the fact that we were interested only in live-stock death losses. In order to hold to a minimum the memory bias usually experienced in obtaining information on livestock at some past date, such as January 1, it was necessary to frame the questions so that a January 1 inventory number could be derived from each report based on questions relating to births, marketings and deaths taking place since January 1 and on inventories at the time the loss questionnaire was filled out. Because losses from other causes, particularly to the new calf and lamb crops, are usually high, steps were taken to sort out losses to 1949 births. Provision was also made to give the respondent an opportunity to report losses due directly or indirectly to the winter blizzards, and to report on the number of cattle and sheep marketed because of injuries suffered during the storm.

In the expansion procedure the averages from the mailed survey were allowed to represent respondents while the non-response interview averages represented non-respondents in the universe. These averages were weighted to arrive at a single statistic for ex-

pansion purposes. In all cases the non-response interview sample provided a downward adjustment in the averages. It was found that non-respondents generally had no losses or lighter losses from the storms than did those operators who had responded by mail. In the analysis the first procedure was to expand the livestock population data to an independent estimate of all livestock on farms as of January 1. This would permit a comparison of the loss survey results with the official State estimate as established by the comprehensive Rural Carrier Survey, which series in turn is based on U.S. Census data. The expansion of the survey data for cattle inventories as of January 1 departed from the official estimate by 6,000 head—about one-half of one percent. In the case of sheep the sample was not quite as accurate with the survey result exceeding the official estimate by about three percent. This departure between cattle and sheep was not unexpected since the sample design was based primarily on the distribution of cattle farms.

Using the cattle data the actual expansion to the January 1 estimate of all cattle on farms follows:

$$(c) \quad \bar{x} = \frac{(\bar{x}_r)(w_r) + (\bar{x}_n)(w_n)}{w_r + w_n}$$

where \bar{x} = Respondents average

\bar{x}_r = Non-respondents average

w_r = Estimated percentage cattle farms represented by respondents

w_n = Estimated percentage cattle farms represented by non-respondents.

TABLE 2

Strata	Ave. all Cattle Per Farm	Number Cattle Farms	Indicated Number Cattle
Storm Counties			
Mailed Sample	116		
Interviews	100		
Combined	103	7,000	721,000
Non-Storm Counties			
Mailed Sample	80		
Adjusted by Interview Ratio	70	4,000	284,000
Total Number			1,005,000 head
Official Estimate			1,001,000 head

The estimate of death losses was then derived through two independent approaches, (a) a direct expansion of the actual losses,

and (b) an estimate of the percentage loss of the January 1 inventory numbers. Again using the survey data for cattle the estimated losses were computed as follows:

TABLE 3. DIRECT EXPANSION

Strata	Ave. Loss Per Farm	Number Cattle Farms	Indicated Number Lost
Storm Counties			
Mailed Sample	6.6		
Interviews	4.4		
Combined	4.9	7,000	34,300
Non-Storm Counties			
Mailed Sample	2.7		
Adjusted by Interview Ratio	2.0	4,000	8,000
Total State			42,300

TABLE 4. PERCENT LOSS EXPANSION

Strata	Percent Loss	Cattle on Farms January 1, 1949	Indicated Number Lost
Storm Counties			
Mailed Sample	5.7		
Interviews	4.4		
Combined	4.7	686,000	32,300
Non-Storm Counties			
Mailed Sample	3.3		
Adjusted by Interview Ratio	2.7	325,000	8,800
Total State			41,000

To summarize then:

TABLE 5. TOTAL CATTLE LOSSES

Method	Storm Counties	Non-storm Counties	Total State
Direct Expansion	\$4,300	8,000	42,300
Percent Loss	\$2,200	8,800	41,000
Adopted Estimate	\$2,000	9,000	41,000

It can be noted that the Livestock Reporting Board adopted an estimate close to the result shown by the Percent Loss approach rather than the Direct Expansion or an average of both. A final estimate in even thousands was desired.

With respect to sheep losses, the same procedures were used and the following results obtained, although the data are considered to be less precise.

TABLE 6. TOTAL SHEEP LOSS

Method	Storm Counties	Non-storm Counties	Total State
Direct Expansion	121,000	37,000	158,000
Percent Loss	128,000	21,000	149,000
Adopted Estimate	125,000	29,000	154,000

Once the total losses were established several other interesting statistics became available. In the 14-storm counties the total loss of cattle was estimated to be 32,000 head (Table 5) of which respondents attributed 20,000 head directly to the storms. Of this 20,000 head, 4,000 head were reported to be 1949 calves. Thus the 16,000 head lost out of the January 1 population, as shown by the survey, finally turned out to be the same as the number estimated in the February (Table 1). The remaining 12,000 of the total 32,000 head lost in the 14-storm counties was attributed to natural causes. In the case of sheep (ewes) in the 14-storm counties, the total loss was estimated to be 121,000 head (Table 6) of which 97,500 head were lost because of direct storm causes. The data reveal that somewhat more sheep were lost in storms occurring after February 1 than were lost in the very severe January weather.

On a percentage basis these livestock losses for the state of Wyoming proved to be heavy but did not approach the unofficial estimates and speculations derived and published during and after the storm period. For cattle the average winter and spring death loss is somewhat less than two percent while the survey shows a loss of 4.1 percent for the 1949 January-June period. In case of sheep the 10-year average winter and spring loss for the state is 5.9 percent compared with the survey estimate of 7.4 percent lost during the January-June period of 1949.

The procedure utilized several of the best features of both mail and interview sampling. The cost was relatively low yet the results were timely and the data possessed many of the fundamental statistical characteristics widely claimed for interviewed samples. In livestock sampling the element of time is of utmost importance with a rapidly changing phenomena. In the case of the non-response interviewing rapport was established almost immediately upon contact since the respondent was already familiar with the survey and its purpose. This fact alone resulted in a very important reduction in interview time and reduced refusals to the point of practical insignificance.

PLANS FOR THE 1950 CENSUS OF AGRICULTURE

RAY HURLEY

Bureau of the Census

FOR many years, the periodic census was the chief official source of data concerning our farms and farm people. While other sources of agricultural data have increased greatly in importance, the Census of Agriculture is still the leading source of statistics on agriculture.

Planning for the 1950 Census of Agriculture began more than two years ago. These plans have been developed by inviting criticism, suggestions, and recommendations from a large number of persons, and by a series of pretests. The first pretests, in April 1948, included a complete census of two Missouri counties and a small-scale census in part of a township in each of 33 other areas scattered throughout the United States. The second pretest, in October 1948, comprised a complete census of four midwestern counties. The third pretest, made last May, included a complete census of two Southern counties, and a census of 64 segments having about 50 farms each and scattered among 43 states. The two most recent pretests have included a recheck by professional personnel for a sample of the farms included in the census. In all the pretests, census enumerators have been accompanied by technically trained persons who, as observers, noted the mistakes made and difficulties encountered in taking the census.

Plans for the 1950 Census of Agriculture may be conveniently outlined in three parts, namely, questionnaires, enumeration procedures, and tabulation and publication of results.

The development of the 1950 Agriculture Census Questionnaire began in 1947. At that time, the principal users of Census of Agriculture data, such as State Agricultural Colleges, State Departments of Agriculture, and farm papers were invited to submit suggestions and recommendations for the next census. From these and other users, several thousand letters containing suggestions and requests for the inclusion of inquiries in the census were received.

In determining the inquiries to be included in the coming census, dependence has been placed largely upon the recommendations of representatives of the principal users of the data. To obtain balance between various interests and to secure assistance in holding the number of questions within feasible bounds, the Director of the Bureau of the Census appointed in 1948 a Special Advisory Com-

mittee for the 1950 Census of Agriculture. This Committee was composed of representatives of agricultural publishers, State Commissioners of Agriculture, the U.S. Department of Agriculture, the American Farm Economic Association, the Grange, the American Farm Bureau Federation, the Farmers Union, and the National Council of Farmer Cooperatives. This Committee has considered and prepared recommendations concerning the numerous inquiries proposed for the 1950 Census.

The questionnaire is of the interview type. In this respect it differs from the previous record-type questionnaires. In the questionnaire most questions are stated completely and exactly as the enumerator would ask them. Experience has demonstrated that it is extremely difficult to get enumerators to understand the exact information desired and to ask the questions in such a way that they get precise information unless the questions are carefully worded and the enumerator uses the wording verbatim. Another important characteristic is the printing of the most important instructions on the questionnaire itself.

Regional or sectional questionnaires were first used in the 1940 census. In 1940 seven and in 1945 nine different regional questionnaires were used. In order to simplify the questionnaire and to obtain information on crops and other items that are important only in a single or a few states, it is planned to use 41 different regional questionnaires in 1950, each for a state or a group of two to four states.

The second part of the plans for 1950 deals with enumeration procedures. These include self-enumeration, training of enumerators, use of crew leaders, and procedures designed to improve the completeness of the coverage of the farm census.

The plan to use self-enumeration for the farm census constitutes the most important departure from field procedures used in past agricultural censuses. Through the use of post office facilities it is planned to distribute, prior to the beginning of the enumeration, to every rural boxholder, except those in a selected area in the South, a copy of the questionnaire for the 1950 Census of Agriculture with a request to the boxholder that these questionnaires be filled and given to the census enumerator when he calls.

Tests on the self-enumeration procedure were conducted in a special census in four rural counties last fall. Notwithstanding the fact that this was a special census and reporting was not obligatory, a rather high rate of cooperation was obtained. The per-

centage of the farms for which the questionnaires were filled either completely or almost completely, ranged from 39 to 51 percent. The percentage of cases in which the respondents had not filled any part of their questionnaires, so that the enumerator had to do the complete job of filling the questionnaire ranged from 42 down to 32 percent. With this rate of cooperation, the average enumeration time for all farms was reduced from about 40 minutes for the areas in which self-enumeration was not tried to about 20 minutes in areas in which it was.

In 1950, it appears reasonable to hope that about the degree of cooperation observed in the pretests can be expected in areas that have about half of the farms in the United States. In the remaining areas, in which the literacy rate of farmers is lower and the enumeration problems are more difficult, only a small gain may be realized through self-enumeration. In fact, in the multiple-unit area of the South, it is not planned to make any advance distribution of questionnaires by mail.

Plans to use sampling in the 1950 Census of Agriculture represent a significant change in procedure from that used in prior decennial censuses. Information on farm equipment, farm facilities, farm expenditures, farm labor, farm values, farm mortgages, and farm taxes will be collected for only one out of five farms, plus about 40,000 large farms. The determination as to which farms are to be the sample will be based upon whether or not the questionnaire has a specified number and the number assigned to the enumeration district. Questionnaires will be numbered from one to five and all questionnaires having a number corresponding to the last digit of the enumeration district will be in the sample. The use of sampling will reduce both the enumeration and tabulation costs for the Census of Agriculture.

Training of Enumerators

The rural enumerators will be given approximately 24 hours of training before they begin their actual enumeration. The detailed training for the Census of Agriculture will represent slightly more than one-third of the total training time. The training program will teach the enumerator the step-by-step procedure for doing his work, and will give him the essential facts he needs to know in order to carry out his assignment efficiently and accurately.

Emphasis in the training will be placed upon practice enumeration in the classroom, use of role-playing interviews, problem-

solving exercises and filling questionnaires from recorded interviews. In addition, each enumerator will be given, after the second day of training, a home assignment of preparing a questionnaire for his own or a neighboring farm. Before the last day of training the enumerator will perform one-half day of actual enumeration. Questionnaires filled at home and those obtained during the one-half day of enumeration will be reviewed, and discussed with the enumerator. The training will be continued during the first two days of actual enumeration. Present plans call for only half the enumerators to start their enumeration on the first day of the enumeration period and the other half to begin their enumeration on the following day. During the first day of enumeration for each group it is planned to have the crew leader see all the enumerators who began that day and to have him accompany, on at least one interview, the two enumerators that he considers the weakest.

The materials to be used for training of enumerators will be standardized and the crew leader will be required to follow a fixed time schedule in conducting the training. In order to reduce the monotony of the training and increase the effectiveness of the presentation of essential instructions, training materials for the Census of Agriculture will include three film strips presenting basic concepts and definitions.

It is axiomatic that the results of the census can be no better than the work performed by the individual enumerator. It is believed that the training program for enumerators will result in decided improvement in the quality of the census.

Noteworthy steps have been taken to provide for supervision of enumerators during the taking of the census. Present plans call for the use of approximately one local supervisor or crew leader for every 14 enumerators in rural areas. These crew leaders will be recruited approximately four weeks in advance of the census date. They will be given a full week of training on the requirements and the procedures of the census.

The crew leaders will conduct the training for the enumerators for whom they will be responsible during the census. Prior to the actual beginning of the census, the crew leader will spend several days inspecting the maps to be used by the enumerators, visiting the area to be enumerated for the purpose of clearing up any questions regarding boundaries of enumeration districts, and familiarizing himself with any problems that may arise during the conduct of

enumeration. During the actual enumeration period he will visit his enumerators as they are conducting the enumeration, inspect their questionnaires on a systematic basis and answer any questions that they may have. In the early stages of enumeration the crew leader will be expected to accompany each of his enumerators on at least one interview. In general, the crew leader will be expected to visit the enumerators at least twice every week and to make a detailed check of approximately 20 percent of the questionnaires they have completed. At the completion of the enumeration of a given area, a crew leader will be expected to check the work and map of the enumerators to see that the coverage has been complete. This program of supervision represents one of the most promising developments aimed toward improving the basic quality of data collected in the Census of Agriculture.

Several important steps are being planned to improve the completeness of the coverage of the agricultural census. The first of these steps relates to the kind of places for which census enumerators will be required to fill questionnaires. It is becoming increasingly difficult for census enumerators to recognize farms or places that should be enumerated in the farm census. In recent censuses, enumerators have been instructed to enumerate as farms all places containing three or more acres on which any agricultural products were produced and also all places under three acres on which \$250 or more of agricultural products were produced during the year preceding the census. Enumerators have had difficulty in applying these instructions particularly because for places under three acres it was necessary to determine the value of agricultural products. Also, in past censuses, enumerators have not uniformly applied the instructions regarding the enumeration of places of three or more acres.

For 1950, the enumerator will be required to ask for each dwelling in rural areas, "Is this house on a farm?" and to record the answer. If the answer to this inquiry is "No" the enumerator will be required to ask, "Is this house located on a place of three or more acres?" If the answer to either of these questions is "Yes" the enumerator will be required to fill an agriculture questionnaire for the place. Moreover, the enumerator will be asked to enumerate all places under three acres if locally considered as farms, and also all nurseries, greenhouses, apiaries, and places producing poultry and eggs primarily for sale.

Tentative plans are to include in the tabulations only those

places of three or more acres on which the value of agricultural products produced during 1949 amounted to \$150 or more. Special rules will need to be developed for farms being operated for the first time in 1949, farms on which all crops failed, etc. Only those places under three acres having a value of products sold of \$150 or more, will be retained in the tabulations. In order to have consistency from census to census, it is planned to vary the \$150 limit in accordance with changes in the price level.

Another important step being taken to improve the completeness of coverage is the use of lists of large farms. The criterion adopted for determining whether or not the farm is large varies somewhat from area to area, but, in general, any farm that has 1,000 acres of land, or 750 acres of cropland, or 200 cattle, or 600 sheep, or a value of products sold of \$70,000 or more is considered a large farm. A list of the large farms enumerated in the 1945 Census has been prepared and copies of this list have been sent to State Statisticians for checking against lists of farms obtained in State farm censuses, lists of large producers, lists of farms included in county soil conservation and other programs. This checking is expected to provide a rather complete and up-to-date list of large farm operators. These lists will be given to crew leaders and they will be required to check upon the enumeration of the farms included on these large farm lists. This procedure will help insure the complete enumeration as well as prevent the enumeration more than once of large farms with land in more than one enumeration district.

Two other procedures for improving the completeness of coverage will be used in the South or the West. The enumeration of "multiple-unit farms" or farms with croppers in the South has always presented serious problems. In order to improve the enumeration of multiple-unit farms, it is planned to use a special Landlord-Tenant Operations Questionnaire in the multiple-unit area of the South. This questionnaire provides for a report on the over-all operations of the multiple unit, a listing of the croppers and other tenants on the multiple unit together with the acreage assigned each and the acreage and production of the crops on the assigned land in 1949. This questionnaire is to be filled by the census enumerator before he fills separate agricultural questionnaires for each of the sub-units of the multiple unit. This procedure will aid in preventing duplication in the enumeration of parts of the multiple units and will provide data for filling the individual agriculture question-

naires in case the operator next April is on a newly assigned acreage and does not know the facts regarding the use of land, crops, etc., for the farm in 1949.

In the West, the use of grazing lands under a permit system presents some difficult problems in obtaining complete coverage of land. Inasmuch as farmers do not know the area of grazing land used under permit, and as several operators often have permits covering the same land, it has been determined that it is not feasible to include grazing-permit lands as a part of the farm or ranch. In order to insure that grazing-permit lands are not included in the farm area and to provide a check on the coverage of persons holding grazing permits, a question on use of grazing-permit lands will be included on the questionnaire for the Western States.

Widespread publicity will be another aid employed in improving not only the completeness of coverage, but also the quality of the census. It is planned to make widespread distribution of information about the census in order to prepare persons for the visit of the census enumerator. The distribution of the Agriculture Questionnaire and its accompanying letter by mail prior to the beginning of the enumeration will contribute greatly to the knowledge of persons living in rural areas regarding the census.

Tabulation and Publication of Results

Present plans call for the tabulation of all items except those obtained only for a sample of farms by minor civil division. Data obtained on a sample basis, except those for farm mortgage debt, farm wage rates, and farm taxes would be tabulated by counties. These tabulations would provide totals for most items for each county and it is planned to publish such county totals. Tabulations and published county totals would provide separate data on farms and crop acreage and production for irrigated and non-irrigated farms in the Western States. Data on land use, the acreage and production of principal crops and on the number of the important kinds of livestock would be available by minor civil division, and such data would be made available, as in past censuses, upon the payment of the cost of making photostat copies of the tabulations.

It is planned to tabulate and publish a considerable amount of data for areas larger than counties. All the cross tabulations by size of farm, color and tenure of farm operator, type of farm, and economic class would be made and published for groups of counties comprising type-of-farming areas. These type-of-farming areas

would be essentially those developed by the Bureau of Agricultural Economics in cooperation with State Colleges.

The classification of farms by size and by color and tenure of operator has been made for several prior censuses. The proposed classification of farms by type of farm and by economic class differ considerably from those made in prior censuses and a description of these classifications appears desirable.

The first attempt of the Bureau of the Census in classifying farms was made in connection with the 1945 Census of Agriculture. Several changes in the 1945 bases for the economic classification of farms are being considered for the 1950 Census. The value of farm products sold instead of the gross value of farm products sold and used by the farm household as the major criterion for the determination of economic class has already been decided upon. In the 1945 experimental classification, the characteristics of farms in the part-time, residential, and small-scale classes do not differ greatly. The proposed inquiries regarding the relative importance of farm and nonfarm sources of income will aid in a more accurate separation of part-time and small-scale farms in 1950.

Changes in price level require also an adjustment in the 1945 criteria for the economic classification of farms in order to provide more adequate comparability through time. Value of sales in terms of dollars fluctuates considerably from census to census because of changes in price levels and yield conditions. This will be partially remedied by change in the 1945 value-of-products criteria.

At the present time the tentative economic classes of farms and the criteria to be used are as follows:

Economic class	Value of products sold	Days of work off the farm by farm operator	Income from non-farm sources greater than value of farm products sold
Commercial farms			
Group A	\$25,000 or more	—	—
Group B	\$12,000-\$24,999	—	—
Group C	\$ 5,000-\$11,999	—	—
Group D	\$ 2,500-\$ 4,999	—	—
Group E	\$ 1,000-\$ 2,499	—	—
Small-scale farms	\$ 200-\$ 999	Less than 100	No
Part-time farms	\$ 200-\$ 999	100 or more or	Yes
Residential farms	Under \$200	—	—
Abnormal farms	This group would include institutions (farms operated by schools, colleges, Federal, State, and local Governments), country estates, and other farms with no farm products sold.		

The classification of farms by type will be made only for those farms that have been classified by economic class as commercial farms, small-scale farms, and part-time farms. Residential and abnormal farms will not be classified by type.

In general, type of farm will be determined on the basis of the relationship of the value of farm products sold from one source to the total value of all farm products sold. Generally, the source accounting for 50 percent or more of the total sales will determine the type. Tentative plans call for the establishment of the following twelve types of farms:

Type of farm	Criteria
1. Cash-grain farms	50% or more of total sales derived from the sale of corn, sorghums, and small grains.
2. Cotton farms	50% or more of total sales derived from the sale of cotton and cottonseed.
3. Crop-specialty farms	50% or more of total sales derived from the sale of a single field crop other than corn, sorghums, small grains, cotton, vegetables, and fruits and nuts.
4. Vegetable farms	50% or more of total sales derived from the sale of vegetables.
5. Fruit-and-nut farms	50% or more of total sales derived from the sale of fruits and nuts.
6. Poultry farms	50% or more of total sales derived from the sales of poultry and poultry products
7. Dairy farms	50% or more of total sales derived from the sale of dairy products, dairy cattle and calves.
8. Livestock-specialty farms	50% or more of total sales derived from the sale of one kind of livestock such as sheep (including wool), cattle and calves (other than dairy) or hogs.
9. General-crop farms	Less than 50% of total sales derived from any single source (such as cash grains, cotton, etc.) but 70% or more of total sales derived from the sale of all crops.
10. General-livestock farms	Less than 50% of total sales derived from the sale of poultry, dairy, or livestock-specialty products, but 70% or more of total sales derived from the sale of all livestock and livestock products.
11. General-crop and livestock farms	Less than 50% of total sales derived from the sale from a single source but with less than 70% of the total sales derived from the sale of crops and less than 70% of the total sales derived from the sale of livestock and livestock products.
12. Miscellaneous farms	This group will include farms not included in the other 11 groups and will comprise such types of farms as forest products, horticultural-specialty, fur farms, etc.

The publications planned for the next census will contain an appraisal of the results of the Census of Agriculture. This appraisal

will be based, in part, on a recheck of the enumeration of a sample of 6,000 to 8,000 farms. This size of sample will be sufficient to provide an accurate evaluation of the completeness of coverage within one percent of the total number of farms. This recheck will not only provide estimates of the completeness of coverage of farms and land in farms but also furnish data that will help evaluate the accuracy of other important items.

The appraisal will also deal particularly with the comparability of various items for several censuses. It will include a discussion of the incompleteness of the enumeration, where this is known to exist, the extent of any estimating involved in presenting the final results, and the basis on which any such estimates were made.

It is believed that this appraisal will help overcome technical criticism of the census and will lead to much more accurate use of its results. It is hoped that self-criticism and analysis of the accuracy of the census will gain for it a higher standing among research and scientific workers.

DISCUSSION

P. J. CREEP

Montana State Statistician

As one who appreciates the value of census data, I am pleased with the opportunity to express some observations regarding the plans for the forthcoming census of agriculture disclosed by Mr. Hurley.

State statisticians are interested in the 1950 Census of Agriculture from the viewpoint of type of information to be enumerated, completeness and accuracy of the recorded data and coverage of the farms and ranches of the state. Basic to these points are the design of the questionnaire, enumerator selection and training, methods of enumeration and checks and measurements of coverage. The following observations place emphasis on these points.

The interview type of questionnaire to be used for the forthcoming census of agriculture is a marked improvement over the record type questionnaires used in the past. Questions worded in a simple, clear and descriptive manner should draw from the respondent correct answers for most items. The Census questionnaire used in the May 1949 pre-test has undergone considerable modification in layout as well as wording of questions. The final draft, with many sections shifted to other positions, will present better sequence of the questions relating to similar subjects.

Narrow regionalization of the questionnaire greatly reduces the number of questions to be considered. This will contribute to the accuracy and completeness of reported information and also lower enumerative costs.

Much of the accuracy, completeness and coverage of the enumeration rests with the type of enumerators used and the kind of training they have. Rather intensive studies have been made of the performance and quality of work of interviewers. Young women raised on a farm or who had lived on a farm for several years proved to be the best interviewers. Enumerators with farm backgrounds would be more likely to cover all farms and ranches in the district than enumerators from the city whose travels seldom take them off State and Federal highways.

Modification of the questionnaire from the record to the interview type has an additional advantage of permitting self-enumeration. Questionnaires are to be distributed through the mail to farm and ranch operators and in due time the enumerators will contact the operators, check through the questionnaires for accuracy and completeness and fill in information not already recorded.

Widespread publicity is to be given the Census to improve its coverage and quality. In the course of this publicity it may be effective to request that operators who do not receive questionnaires by mail at a specified date appear at a designated office and obtain questionnaires for self-enumeration.

Mr. Hurley has outlined the plans to assure more complete coverage of multiple unit farms and also those which use grazing lands under a permit system. A large portion of the land in western states is operated under rental agreements and many farms are comprised of two or more tracts of land which may be widely separated. If complete coverage is to be obtained, it may be necessary for enumerators to account for all of the land within the borders of their districts by thorough mapping.

Constant changing of land from one operator to another induces a problem in the enumeration of land use and crop information in western states. This problem was recognized and discussed by most of the observers of the May 1949 pre-test. The first question under the land use section of the questionnaire asks for "acres in this place" which are to be the same as the acres in the operator's charge at the time of the enumeration. This acreage is also to be the same as that covered in the land use categories for the year 1949. Included in the land use section is a question asking for acres of land from which crops were harvested in 1949 and these acres are expected to be the same as the total of the acres entered under the crops section of the questionnaire. There will, undoubtedly, be many cases in Montana and other western states where land operated in 1949 will differ from the land in the charge of the operator next spring. Mr. Hurley has indicated that by use of a special landlord-tenant operations questionnaire the enumeration of multiple unit farms in the south may be improved. It would be well to use a similar questionnaire in most of the western states.

The mid-decennial Census of Agriculture timed as of January 1 eliminates much of the confusion of shifting acreages in farms and also reduces the amount of memory bias. Furthermore the majority of farmers and ranchers operate on a calendar year basis. They have on hand January 1 livestock numbers, totals of income and expenses and other data for income tax purposes. These data would be useful and timely in filling out the census

schedule. Thus a January 1 enumeration appears to have many advantages over the 1950 enumeration date which is to begin April 1.

During recent years the need for good irrigation statistics has increased sharply.

The irrigation section of the 1950 census questionnaire does not provide for a listing of acreage and production of crops for which part of the acreage was irrigated in 1949.

The livestock industry in western states is comprised principally of large scale ranching operations. With the census enumeration timed for April 1, 1950, enumerators should be able to locate owners or operators at their home place. Reference to assessor's records and also to files of the various Federal agencies controlling public domain will, undoubtedly, be helpful in obtaining complete coverage of western livestock operations.

DISCUSSION

JOE R. MOTHERAL

A & M College of Texas

My interest is centered on research uses of Census data, so I should like to mention three of the most important values of the Agricultural Census to the researcher.

First, the Census is highly suggestive of problem areas in the agricultural economy and is therefore influential in the formulation of research projects. Second, it is logically and widely used as a sampling base for intensive studies. And third, it provides a check every five years on those studies which are concerned with trend analysis. For these reasons, and because the Census is an established public undertaking of rather sizeable proportions, the agricultural economist tends to assume a proprietary attitude toward it and to reserve unto himself the privilege of full, free, and perhaps at times noxious, criticism of the methods pursued by the Bureau of the Census in collecting, processing and publishing its data.

In his paper Mr. Hurley implicitly accepts this universal tenancy in common and enumerates the ways in which his Bureau has encouraged it, to the end that a more acceptable and useful product may be the result. A deliberate effort has been made to obtain the advice of representatives of the farm organizations, the agricultural press, and the state commissioners of agriculture.

It is the thesis of these comments that while the agricultural economist is correct in asserting his right to criticize Census techniques, he has the responsibility of contributing to their improvement. We have accepted the right with greater alacrity than the responsibility. A case in point is the matter of enumerating the multiple unit, or plantation, in the South. Most Southern agricultural economists yield to no region in their condemnation of the traditional Census classification of farms. Some consider it simply to be an anachronism which the Bureau is unwilling to discard, others as a concession to easy enumeration; and there is one steadfast group which

takes the dark view that it is sheer discrimination resulting from the indecisive nature of the Confederate victory in the Civil War.

In 1910 the Bureau of the Census offered a partial remedy in the form of a report entitled "Plantations in the South" which summarized data for farms having five or more tenants. A plantation schedule was used in 1940, but the results were evidently unsatisfactory, as the data have not been published. Again in 1945 an attempt was made to collect and summarize information on "Multiple Unit Operations." Among the other limitations of this material is that of lack of comparability, for the definition of a multiple unit in 1945 involved *any* operation consisting of two or more sub-units including those of cash, standing rent, and share tenants.

Since 1945 the Bureau has made a strenuous effort to overcome this deficiency in time for the 1950 Census, as those of us who assisted in the field pretests can testify. However, it is an open question whether the schedule presently proposed for 1950 will do the job.

Admittedly, the solution to this problem is not simple. It requires a reconciliation of the intricate characteristics of the Southern tenure system, on the one hand, with the pressing limitations of time, schedule space and the capacity of the Census enumerator on the other. Most Southern agricultural economists, I believe, need to have a clear-cut enumeration of operating units which would be meaningful and uniform for the region, and which would assure comparable data from one Census to the next.

An admirable illustration of how to hold a firm grip on this statistical cake, while eating it, has been furnished by the summarization of farms into "economic classes." This exceptionally useful classification required no modification of existing methods of enumeration and hence involved no breach in continuity. Yet it represents an adaptation that meets a long-standing need for students of significant trends in the agricultural economy. It is worth noting that the proposal for this addition to Census material originated outside of the Bureau but was readily accepted and incorporated into the 1945 Census.

The final objective of the consumer of agricultural statistics might well be an annual census with sufficient coverage to provide reliable data for small areas. Considerable progress has been made toward such a goal during the last few years.

DISCUSSION

R. S. OVERTON

Iowa Field Office BAE.

The Census Bureau is to be highly commended for their energetic efforts to make extensive improvements in all phases of their work. In conjunction with their program of inviting assistance from outside sources, the Census people themselves have aggressively tackled their problems with the view of adopting or devising new techniques that would improve the quality and utility of their data.

Several specific improvements should be cited. One of the most impor-

tant is the nearly complete regionalization of questionnaires on a state basis.

Another change in the procedure is the standardized training program that has been worked out. The combination of film strips and recordings is a significant step toward uniformity and should go far toward improving the reliability of the census enumeration.

The proposed self-enumeration plan is basically sound and represents another achievement.

The Bureau is making every effort to formulate realistic classification and type criteria that will maximize the value of the tabulations. These standards have not yet been fixed and since the Bureau is inviting comment it would seem that there still is an excellent opportunity for all of us to offer constructive advice as to how we would like to see the results published.

In the future, I would like to see a census study committee, composed of personnel from B.A.E., P.M.A., the state colleges, the State Department of Agriculture, the Extension Service, business groups and representatives of farm organizations set up in each state. This group would function much the same as the national advisory committee except that they would be concerned with the work in a particular state.

The time of taking the Federal Census of Agriculture needs to be re-examined. In my opinion the information should be obtained in December or January, at least it should be as close to the first of the years as possible. Obviously there are some drawbacks to an earlier enumeration, but I feel the advantages outweigh the disadvantages.

It is my opinion that dollar value figures are still regarded by rural people as highly personal information and they resent being questioned about them. Further, many crop share tenants do not know how much their landlord received from the sale of his portion of the crop. In short I am rather dubious about all of these "values of sales" questions and I would like to raise the point that their inclusion may result in serious downward bias in the reported figures of both dollar values and units sold. This influence may go even further and tend to distort reported production figures.

**PROCEEDINGS OF THE ANNUAL BUSINESS MEETING
AMERICAN FARM ECONOMIC ASSOCIATION
LARAMIE, WYOMING, AUGUST 20, 1949**

President O. V. Wells called the meeting to order at 8:30 A.M. He asked for the reports, in turn, of the Committee of Election Tellers, the Secretary-Treasurer, the Auditors, and the Editor. These reports were presented and are appended. A motion to accept these reports was approved.

President Wells reported the arrangements for joint meetings with the American Economic Association and related organizations in New York in December.

The President announced the appointment of a committee consisting of A. J. Brown, M. C. Bond, and D. Barton DeLoach to cooperate with the American Marketing Association.

Wells reported that he had been unable to form a committee to make special awards at this meeting. Several prominent members were asked, but refused, to serve as chairman of such a committee. However, E. C. Young, Warren Waite, and F. V. Waugh served as a committee to make recommendations as to procedures for making special awards.

The President discussed the prospective deficit in the Association's budget for the current and next fiscal years. He pointed out that publishing the JOURNAL is the greatest item of expense but advised against reducing the size of the JOURNAL. The executive Committee has authorized the publication of 1,200 pages, including 400 pages for the proceedings of the annual meeting.

Several members spoke of the necessity for the Editor to cut proceedings papers to fit the limited space in the JOURNAL. There was no dissent.

A motion to supply authors with reprints of proceedings papers at cost was approved.

A motion to charge a registration fee of not less than one nor more than two dollars at future annual meetings was approved.

The President discussed the need for greater continuity of officers in the management of the affairs of the Association. He gave special emphasis to the need for some specific preparatory experience for the President. In order to provide for such experience, the Executive Committee recommended the adoption of the following amendment to the Constitution.

Article IV

Organization. The officers shall be a President, a *President-Elect*, two Vice-Presidents, and a Secretary-Treasurer, who shall be elected for one year, and who shall serve until their successors shall qualify. In case of incapacity of the President to act, the Vice-President receiving the highest number of votes shall act as President. *The President-Elect shall be a member of the Executive Committee in full standing and automatically become President the year following his election as President-Elect.*

The Executive Committee shall consist of the active officers, *including the President-Elect*, the latest two past Presidents, and may include the President of any national or regional association with which the American

Farm Economic Association has entered into joint membership arrangements. It shall appoint annually the Editor of the JOURNAL OF FARM ECONOMICS. It may adopt rules and regulations for the conduct of its business not inconsistent with the constitution of the Association, or with rules adopted at the annual meeting. It shall act as a committee on time and place of meetings, and perform such other duties as the Association shall delegate to it.

There shall be a standing committee on investment policy with respect to Association funds. The Secretary-Treasurer shall be a member of this committee. He shall have authority to acquire, sell and transfer property for the Association. The actions of this committee shall be subject at all times to review by the Executive Committee.

The President, Vice-Presidents, and such other members as the President may appoint shall constitute a committee on the preparation of a program for the annual meeting. The President shall act as chairman of this committee.

Special committees may be appointed in accordance with the needs of the Association. Special committees and the investment committee shall be appointed by the President with the approval of the Executive Committee.

(As amended 12-28-1946)

Article V

Election of Officers. The President and the two preceding past Presidents shall constitute a nominating committee. The President shall act as chairman of the committee.

Two nominations shall be made for each office except for Secretary-Treasurer, for which one nomination shall be presented. No person who has served a term as President shall be nominated for that office or eligible for election to it. *For the year ending in 1950, the ballots shall provide for the election of both a President and a President-Elect. Thereafter the ballots shall omit the office of President.*

Not later than 30 days before the annual meeting of each year, the Secretary-Treasurer shall mail a ballot to each member of the Association who has paid dues for the current year, not including corporations, libraries, or other institutions. Said ballot shall provide for a vote for each elective officer. For each office the ballot shall contain one blank line. A brief biographical sketch of each nominee shall be included.

The proposed amendment was approved.

There being no further business to be transacted, the meeting was adjourned.

L. H. SIMERL, *Secretary-Treasurer*

REPORT OF THE SECRETARY-TREASURER

The secretary-treasurer spent considerable time becoming familiar with the duties and responsibilities of his office. Among other things this served to increase his appreciation of the work of those who performed these duties in previous years.

Membership. The strong upsurge in membership that began a few years ago apparently has subsided. Last December the secretary-treasurer reported an all time high of 2,006 members and subscribers. Our latest count, made in connection with the mailing of the election ballots, showed a decrease of approximately two and one-half percent from the last December figure.

The Association is confronted with a serious membership and financial problem. This problem has five alternative solutions. These are: (1) cut services to members; (2) finds ways of providing present services at reduced cost; (3) increase membership dues; (4) draw upon reserves; (5) increase the number of members.

A Committee on Policy faced this problem in 1948, and reported at the last annual meeting. At that time the committee, consisting of Frederick V. Waugh, Chairman, L. J. Norton and E. L. Butz, recommended against curtailing our program or raising dues and said: "Our greatest need is for new members."

Finances. From December 1 to July 30 our operating expenditures have exceeded income by \$1,086.01. In addition, we accumulated a liability for clerical services in the secretary-treasurer's office amounting to \$875. This makes a total deficit for the first eight months of our budget year of \$1,961.01.

Figures presented at the last annual meeting are not exactly comparable to these as they covered a period of nine months instead of eight. However, for the first nine months of the fiscal year 1948 income exceeded expenditures by \$1,817.76.

Thus, where we had a surplus of \$1,817.76 to September 1 last year, we have a deficit of \$1,961.01 to August 1 this year. This switch from a substantial surplus to a substantial deficit should receive careful consideration from the members and the Executive Committee.

The change from black ink to red is accounted for by increased operating costs on the one hand and reduced income on the other. Operating costs have increased with the general rise in prices, and also on account of the large increase in membership last year. The dues paid by the new members appeared as income in 1948, but much of the expense of servicing them occurred in 1949. Many of the new members failed to renew their membership this year.

A summary of our receipts, expenses, and cash balances follows:

SUMMARY OF RECEIPTS, EXPENSES, AND CASH BALANCES
DECEMBER 1, 1948 TO JULY 30, 1949

Cash balance, November 30, 1948.	\$ 6,035.16
Income	
Special grants	\$1,000.00
Dues and other income	9,253.64
Total.	\$10,253.64
	\$16,288.80

Expenses

JOURNAL printing..	\$8,985.37
Other expenditures.	1,354.28
	<hr/>
Total	\$10,339.65
	<hr/>
Cash balance July 30, 1949.	\$ 5,949.15

Investments

No changes have been made in the investment portfolio since the end of the fiscal year, November 30, 1948. At that time the investments were valued at \$61,744.85.

Special Grants Fund

The reserve for special grants amounts to \$14,425.00 plus accumulated earnings since December 1, 1948.

A summary of the financial results and membership records will be prepared at the end of this fiscal year, November 30. It will appear in the February 1950 issue of the JOURNAL.

In accord with a resolution adopted by the membership at the 1948 annual meeting the fiscal year beginning next December 1, will end on June 30, 1950.

Respectfully submitted,
L. H. SIMERL,
Secretary-Treasurer

REPORT OF THE AUDITORS

As requested by the President of the American Farm Economic Association, we have examined the accounts of the Secretary-Treasurer, L. H. Simerl, for the period ending July 30, 1949. We found that the books were kept by the retiring Secretary-Treasurer, L. J. Norton, for the period October 30-December 22, 1948. The assets of the Association were checked by examining bank statements and inspecting the stock certificates and bonds kept in a safety deposit box in the First National Bank, Champaign, Illinois. We have checked cancelled checks, bank debit slips, vouchers, and bank statements with expenses as shown in the treasurer's account and found the book statement of expenses correct.

We have checked bank deposit slips, bank credit slips, and bank statements with receipts as shown in the books, and found the book statement of receipts correct. We checked the bank balance on July 30, 1949 with the books and found them in agreement.

The books of the Association have been carefully and correctly kept, and we certify that the financial statement made by the Secretary-Treasurer reflects the financial situation and the transactions of the Association as shown by his records.

Respectfully submitted,
H. C. M. CASE AND
N. R. URQUHART, *Auditors*

MINUTES OF THE EXECUTIVE COMMITTEE, AMERICAN
FARM ECONOMIC ASSOCIATION, LARAMIE, WYOMING,
AUGUST 17, 18, AND 19, 1949

President Wells called the meeting to order at 10:00 A.M. Those present were: O. V. Wells, Bushrod Allin, T. K. Cowden, Asher Hobson, H. R. Wellman, S. C. Hudson, and L. H. Simerl. Also present later were Walter Wilcox and the President-Elect, Warren Waite who presided at the meeting on the 19th.

The minutes of the latest previous meeting of the committee were approved.

The Committee agreed to invite ten persons who rendered special services essential to the success of this annual meeting to be guests of the Association at the banquet.

A motion authorizing the President and the Secretary-Treasurer to fix the amount of the bonds for the latter officer and his secretary was approved. The Committee suggested \$10,000 and \$5,000, respectively.

The President reported that he had been unable to form a committee to begin the special awards program this year. He said that E. C. Young, F. V. Waugh, and Warren Waite had been appointed and had served as a committee to make recommendations as to how such a program might be administered. The report of this committee was received and referred to the President-Elect.

Bushrod Allin reported on problems and progress in the organization of student sections or chapters. The Committee agreed that the AFEA should encourage and advise with student organizations interested in agricultural economics, but should not undertake to issue charters, approve constitutions, or otherwise intervene in the management of these organizations. It was further agreed that undergraduate students should be accepted for membership in the Association on the same basis as graduate students, that is, upon certification by the head of the department giving instruction in agricultural economics and the payment of an annual membership fee of \$3.00.

Dr. Hudson, on behalf of the Canadian Agricultural Economics Society, invited the Association to hold its annual meeting in Canada in 1951.

Dr. Cowden, on behalf of the Michigan State College, invited the Association to meet at East Lansing in 1951 or any succeeding year.

E. C. Young reported on the possibility of the International Conference of Agricultural Economists being held in the U.S.A. in 1951. In that event the AFEA should consider the advisability of coordinating its annual meeting with that of the International group.

Mr. Wells reported on arrangements for joint meetings with the American Economic Association and related societies in New York in December.

The Committee agreed to recommend to the members that a registration fee of \$1.00 be charged at the next annual meeting. This would help meet expenses of the meeting and balance the budget.

The Secretary-Treasurer was instructed to prepare membership and financial reports as of June 30, 1949 that can be used for comparative purposes for the fiscal year ending June 30, 1950. He was also requested to prepare and publish comparative reports as of the end of the current fiscal year.

Walter W. Wilcox was appointed Editor of the JOURNAL for the next year.

In order to furnish transfer officers of corporations with the necessary evidence that the Secretary-Treasurer is authorized to transfer securities in the name of the Association, the following resolution was adopted.

"RESOLVED, that the Secretary-Treasurer (L. H. Simerl of Urbana, Illinois) who is also Chairman of the Investment Policy Committee, be and is hereby authorized and empowered, for, and in the name and on behalf of this Association to take any and all such steps, and to do any and all such things, as may be necessary, required, and appropriate for, or in connection with, the purchase, acquisition, acceptance, handling, pledging, sale, or other disposition of stocks, bonds, and other securities belonging to the Association or pertaining to its business, including the execution, and delivery for and in the name and on behalf of the Association, of any and all endorsements, transfer and assignments of certificates of stock, bonds, or other securities standing in the name of this Association, either for the purpose of sale or transfer, and all such other steps and actions as may be necessary or proper in connection herewith."

The President was authorized to proceed with the special awards program as previously recommended by the Committee, except that the awards for published research consist of three awards of \$250 each.

It was agreed that the 1950 annual meeting would be held at Montreat, North Carolina.

The President, or someone to be named by him, was authorized to go to Montreat to make necessary arrangements for the meeting.

The Executive Committee directed the Secretary-Treasurer to change the membership to a calendar year basis as rapidly as practicable. This change is desirable in the interest of economy and budgeting.

It was agreed that a directory, if prepared, should be sold to members at cost.

Methods of increasing revenues were discussed. These included increased sale of subscriptions to commercial concerns, increased membership in foreign countries, and the sale of more advertising in the JOURNAL.

The Committee agreed to recommend to the membership an amendment to the constitution to provide for the election each year of a President-Elect who would serve as a member of the Executive Committee for one year before becoming President.

The Secretary-Treasurer presented a report indicating a probable deficit of \$1,100 for the fiscal year ending November 30.

Budget estimates for the next twelve-months' period were approved as follows:

Income

Dues and subscriptions	\$9,000
Sale of back numbers	500
Sale of JOURNAL reprints	300
Dividends and interest	2,000
Advertising	100
Total Income	\$11,900
Deficit	1,100
	\$13,000

1304 PROCEEDINGS OF THE ANNUAL BUSINESS MEETING

Expenditures

Printing JOURNAL.	\$9,000
Reprints.....	600
Annual meeting	300
Back numbers...	200
Best article award.. . . .	100
Editorial expense.	750
Library custodian.	30
Office supplies.	120
Postage and wires.. . . .	200
President's expense.	150
Secretary's expense	1,550
	\$13,000

The Executive Committee on behalf of the membership adopted the following resolution expressing appreciation to Dr. Vass and the staff of the University of Wyoming.

"The Association takes this means of expressing our sincere appreciation of the many and varied efforts of the staff of the University of Wyoming which made possible not only the largest, but one of the most pleasant series of meetings in this our first, but we hope not our last, joint session with the Western Farm Economic Association"

There being no further business to come before the Committee, the meeting was adjourned.

L. H. SIMERL, *Secretary-Treasurer*

REPORT OF THE ELECTION TELLERS

We, the undersigned election tellers, report that we have counted the ballots cast for the Association's officers for the year 1949-50. The officers elected are as follows:

President.	Warren C. Waite
Vice-President.	Joseph Ackerman
Vice-President.	K. H. Parsons
Secretary-Treasurer.	L. H. Simerl

Respectfully submitted,
(Signed) BUSHROD W. ALLIN
T. K. COWDEN

ANNOUNCEMENT OF AWARDS FOR MERITORIOUS RESEARCH IN AGRICULTURAL ECONOMICS

During the year 1948, the special grants committee of the American Farm Economic Association solicited funds from business firms and enterprises for the purpose of establishing a fund from which awards could be made for meritorious research. At the time of the annual meeting in September, 1948, Chairman Julius Hendel reported that \$12,925 had been contributed towards this fund. Following this date the committees of the Farm Economic Association have been at work developing a plan by which special awards could be made out of this fund.

At the annual meeting of the Association in Laramie in August, 1949, a program was adopted for making the first awards during the year 1949-1950. Following is a brief statement of the conditions under which these awards will be given.

There are two types of awards: (1) For published reports of research in the field of Agricultural Economics, and (2) For theses submitted in partial fulfillment for the degree of Doctor of Philosophy in departments administering majors in Agricultural Economics.

Awards for Published Reports of Research in Agricultural Economics

1. For the year 1950 there will be three prize awards of \$250.00 each. Each award will be in a different field of Agricultural Economics.

2. Papers which are submitted will be classified in the following fields and persons submitting the papers should indicate the field in which they believe they should be classified.

- (a) Farm management and production economics
- (b) Agricultural marketing
- (c) Agricultural prices
- (d) Agricultural finance
- (e) Land economics
- (f) Theory and methodology
- (g) Agricultural policy

3. Selections will be made from published research bearing the publication dates of 1947, 1948, and 1949.

4. Only papers submitted by persons 40 years of age or less at the time of publication will be considered.

5. The prize awards committee will be made up of seven persons representing the various fields which have been designated. All will be members of the American Farm Economic Association.

6. Papers should be in the hands of the Chairman of the committee, E.C. Young, Purdue University, on or before February 1, 1950.

7. Members of the prize awards committee will not be eligible to submit papers of their own.

8. Announcement of the awards will be made on or before the time of the 1950 annual meeting of the American Farm Economic Association.

Awards for Doctor's Theses

1. For the year 1950 the awards will be as follows: (a) First award will be \$250.00, and (b) two special awards of \$100.00 each.

2. Theses in any field of Agricultural Economics may be submitted. Theses prepared by candidates for the Ph.D. degree in any department of Economics or Agricultural Economics in the United States are eligible for consideration.

3. Selections will be made from theses submitted during the calendar years 1947, 1948, and 1949.

4. The head of each department of Agricultural Economics or Economics in the United States where Ph.D. programs are administered will be eligible to submit one thesis.

5. Theses should be in the hands of the Chairman of the Committee, E. C. Young, Purdue University, on or before February 1, 1950.

6. The prize awards committee will be made up of three persons, all of whom will be members of the American Farm Economic Association.

7. Announcement of the awards will be made on or before the time of the 1950 annual meeting of the American Farm Economic Association.

8. No paper shall receive more than one award but a published Doctor's thesis may be submitted in both classes.

WARREN C. WAITE, *President*
American Farm Economic Association

REPORT OF THE EDITOR

The new editor took over his duties beginning with the May 1949 issue. Every effort was made to continue the high standards maintained by the retiring editor. The following tabular data indicates the use made of the JOURNAL pages in 1949 as compared with 1948. (The Proceedings of the Annual Meeting held in 1948 and printed in February 1949 are included in the statistics for 1948.)

		<i>1948</i>	<i>1949</i>
Articles in regular issues	Number	33	33
	Pages	550	519
Notes in regular issues	Number	23	24
	Pages	137	126
Book Reviews in regular issues	Number	30	31
	Pages	67	68
News Items in regular issues	Pages	26	26
Papers in Proceedings	Number	80	59
	Pages	451	486
Discussion in Proceedings	Number	24	25
	Pages	82	45
Number of Different Authors in Regular Issues and Proceedings			
		177	168

The Executive Committee at its last meeting instructed the editor to keep the Proceedings issue within 400 pages and set a maximum of 1200 pages for the year. Since the editor was unable to keep the Proceedings within the designated number of pages, an attempt will be made to keep the regular issues down to 175 pages and yet print as many articles as before. The cooperation of the membership in submitting somewhat shorter articles will be appreciated.

WALTER W. WILCOX

INDEX TO VOLUME XXXI

1949

SUBJECTS

(Due to duplication in page numbers, those from the February, 1949
PROCEEDINGS issue are indicated by a p following the number.)

- Acreage limitation in Federal irrigation projects with particular reference to the Central Valley Project of California, 973
 - Discussion, 982, 983
- Actuarial Structures for Crop Insurance, 418

Important McGRAW-HILL Books

FARM WOOD CROPS

By JOHN FREDERICK PRESTON, U. S. Soil Conservation Service *American Forestry Series*. 304 pages, \$3.75

A technical guide to the development of a farm-woodland enterprise integrated with the farm business. The book shows why the farmer should grow wood as a farm crop and how he should take the first steps in farm woodland management.

RURAL LIFE IN PROCESS

By PAUL H. LANDIS, The State College of Washington. *McGraw-Hill Series in Sociology and Anthropology*. Second edition. 538 pages, \$4.00

Describes the effects of contemporary social forces on personality, institutions, and problems of rural society in the United States, integrating and interpreting rural life from a functional viewpoint, presenting it throughout in cultural perspective.

AGRICULTURAL ECONOMICS

By B. H. HIBBARD, University of Wisconsin. 442 pages, \$5.00

This book presents in simple language and familiar terminology the main economic facts pertaining to the operations and relationships involved in farming under modern economic, political and social conditions.
